

Operations and Maintenance Plan

FINAL

Operations and Maintenance Plan Cambridge Bay Soil and Water Treatment Facility V.1 January 2017

Plain Language Summary

This Plan outlines how KEL will operate and maintain the soil and water treatment facility (SWTF) in Cambridge Bay, Nunavut (the Hamlet). The facility will include one bermed and lined area for soils contaminated with petroleum hydrocarbons, a lined water and snow retention/storage area and a lined and bermed hazardous waste storage area. Soil is treated by a mechanized process combined with the potential application of amendments to the soil to facilitate microbial activity to break down the pollutants. Once treated, soil will be reused as alternate daily cover at the Hamlet's Landfill or re-purposed as permitted. Water will be treated using an onsite water treatment plant and once treated will be used to increase moisture at the soil treatment facility or discharged as per requirements outlined within the issued water license. The waste storage area will be used to temporarily store waste that requires containerization and/or shipment to an authorized location. Any soil or water that cannot be treated at the facility will be transported to a licensed waste receiving facility for disposal.

1.0 Purpose and Scope

The purpose and scope of this Plan is to outline the methodology for operating and maintaining the SWTF. The location drawing can be found in Appendix B and the design drawing of the facility in Appendix C.

KEL manages operations responsibly and will comply with all licenses, permits and applicable territorial and federal laws and regulations related to Facility operations and maintenance. The following table lists regulations and guidelines applied to and referenced for Facility operations.

a) Project Description

The purpose of this project is to construct and operate a permanent SWTF in Cambridge Bay, Nunavut. Following bioremediation, treated soil meeting landfill criteria is reused as Alternative Daily Cover (ADC) at the town landfill or re-purposed. Soil not meeting reuse criteria is transported off site for disposal at a suitable facility. Water will be treated using an onsite water treatment plant and once treated will be analyzed and discharged as per territorial regulations.

The Facility includes: one engineered cell consisting of three sub-cells: one cell 50 m x 40 m, for receipt, storage and treatment of petroleum hydrocarbon-contaminated soil; one cell designed for storage of up to 170 m³ of petroleum hydrocarbon-contaminated snow and water; one cell 19 m x 14 m designed for storage of hazardous waste awaiting shipment; one small package

treatment plant to treat petroleum hydrocarbon-contaminated water; one or two above ground storage tank(s) (AST) for treated water storage; one small shed for storage of supplies, documentation and health and safety equipment.

The SWTF is intended to be constructed commencing in summer of 2017. The facility is anticipated to be operated for a term of five (5) years at which time its use to the community will be re-evaluated.

2.0 Environmental Management

The Facility will be located within the hamlet limits on an existing lease adjacent to the hamlet of Cambridge Bay sewage lagoon. Land disturbance as a result of the construction and operation of the Facility will be minimal and not greatly alter existing site condition. Based on facility design, operating principles and monitoring plan the environmental impacts associated with this facility will be minimized.

3.0 Soil and Water Treatment Facility

The Facility is designed to treat petroleum hydrocarbons. Materials received at the site for treatment include petroleum hydrocarbon-contaminated soil and/or water and snow, from off-site sources including residential, commercial and industrial properties where a hydrocarbon spill or leak has occurred. Prior to receipt on-site, contaminated soil will be profiled which may include sampling and field testing to determine suitability for treatment. Soil meeting acceptance criteria is deposited into an engineered cell, operated as a Soil Treatment Facility.

Once the bioremediation process has been given adequate time, soil is sampled and tested to confirm it meets discharge/beneficial reuse criteria (as presented in Appendix A). Soil meeting reuse criteria is hauled as cover material at the Hamlet's landfill or re-purposed as permitted.

The Facility will also include an engineered pond to accept petroleum hydrocarbon contaminated snow and water. Snow and water will be profiled for acceptance either by analytical testing and/or MSDS sheet and be accompanied by a movement document prior to acceptance at the site. Runoff water from the soil treatment facility and contact water from the hazardous waste storage area will also be deposited into the water storage pond. Once snow melts, water from the storage pond will be treated using an onsite water treatment plant and then tested to analyze for the discharge guidelines set forth in the license.

a) Facility Design

The facility has been designed to receive up to 3,000 m³ (a drawing of the Facility Plan and Section is provided in Appendix B). The cell is 50 m by 40 m, surrounded by a soil berm approximately 1.5 m tall with 2:1 side slopes measured from existing grade. The base of the cell is graded to a 1.0% slope on the long axis, away from the entrance ramps to control and direct interior drainage towards the water storage cell.

At least 0.2 m of soil fill <8mm in diameter, debris, and organics (protective fill) covers the base of the cell and the sides of the berm to protect the overlaying geomembrane against punctures. A Solmax 460ST 60 mm single textured high density polyethylene (HDPE) liner (or equivalent) covers the cell floor, overlaps the crest of each berm, and is anchored into the side of the perimeter berms. A 16 oz non-woven geotextile overlays the geomembrane as a precaution against punctures, and is anchored into the perimeter berms. Approximately 500 mm of fill free from debris and organics overlays the geotextile on the base of the cell, for torsion protection from turning vehicles. At least 300 mm of fill overlays the interior side slopes of the berms.

b) Biotreatment Facility Operations

All soil transported to site requires a waste profile including analytical testing and suitable movement documents prior to receipt on-site. An example of a typical waste profile form is included in Appendix E. If this information is absent or incomplete, or materials do not meet the acceptance criteria listed in Appendix A, soil is not received into the Facility and will remain the responsibility of the generator. In some cases, such as spills and emergency response, soil may be accepted into the facility and samples collected after receipt. Department of Environment (DOE) and Indigenous and Northern Affairs Canada (INAC) representatives will be notified in this situation.

Once quality and quantity of soil are approved for receipt at site, soil is end-dumped into a designated area of the cell, and placed in biopiles in a fashion to facilitate segregation and ease of access for equipment or technical staff to complete required sampling and treatment campaigns. Soil is managed in biopiles with an average height of up to 3.0 m using a hydraulic excavator or dozer. Once placed, each biopile is labelled with a unique identifier and documented. Each waste shipment is managed and treated separately. Efforts are made to avoid comingling of wastes and dilution of contaminated soils with cleaner soils.

Typically, two or three treatment events occur each year over the summer season. Treatment may occur using a track hoe equipped with an Allu bucket or by manual aeration using an excavator. Materials are quickly churned and aerated by thorough mixing, blending and aeration while all unwanted debris is removed manually. The final waste soil matrix is a finely processed material suitable for beneficial reuse.

Treatment does not occur when the ambient air temperature is below 5°C. The mean expected residency of soil undergoing bioremediation in the Soil Treatment facility is one year however soils with recalcitrant contaminants may require longer treatment times.

There may be times throughout operations wherein it may be necessary to add amendments to the soil to promote effective and efficient breakdown of hydrocarbon constituents. Typical amendments include fertilizer to stimulate natural microflora activity, water to adjust moisture content, and lime to modify pH. In more extreme circumstances other soil conditioners such as surfactants can liberate hydrocarbon from soil particle adsorption to promote bioavailability, or peroxides to promote oxidation of chemical constituents. In the event that any of these are required, MSDS will be provided, located in a small storage shed on site and be accessible to all

workers. Any amendments will be procured for immediate use; no long term storage on site is expected. Over the short term, amendments will be stored within appropriate containment in the locked shed on site. All soil amendment application, will be conducted by KEL personnel experienced in waste facility management and operation.

Prior to commencement of operations for the year, KEL staff and contractors working at the Facility will be given an orientation on operations, safety and routine practices at the site.

c) Soil Sampling

To assess the progress of remediation, a photoionization detector (PID) may be used or grab samples collected and tracer tests carried out during the first or second treatment campaign. Once it is determined that a remediation end point has likely been reached, formal soil sampling occurs to determine compliance with reuse criteria. Following the sampling protocol outlined below, along with avoiding comingling of soils between biopiles, efforts are made to ensure that confirmatory sampling is unbiased and representative, and contaminated soils are not diluted with cleaner soils.

Sampling involves establishing sample points in each biopile: one representative sample is collected for the volume of remediated soil specified; this is consistent with confirmatory sampling for soil removal from landfarms in Yukon Territory (Environment Yukon 2011) and confirmatory sampling of ex situ stockpiles in BC (BC Ministry of Environment 2009). Each representative sample collected is composed of five sub-samples. Each sub-sample is collected from one of five areas or 'cells' within each, wherein each of the five cells is equivalent to 20% of the soil volume specified in the sampling protocol found in Appendix A. Multiple specimens from within the cell can be collected for each sub-sample, reducing the "nugget effect" that can arise when small sample volumes are collected from a stock pile; this is consistent with BC's Technical Guidance on Contaminated Sites for Site Characterization and Confirmation Testing (BC Ministry of Environment 2009). Samples will be collected by trained personnel using either handheld implements such as a hand auger or shovel or with the assistance of mechanical equipment such as an excavator.

Quality Assurance/Quality Control (QA/QC)

All samples are collected in laboratory prepared containers, stored in temperature-controlled coolers, transported and submitted to a Canadian Association for Laboratory Accreditation (CALA) accredited laboratory for analysis of contaminants of concern. KEL follows appropriate chain of custody control mechanisms during transportation of samples to the laboratory.

Samples are collected and submitted for QA/QC purposes including collection of: 10% blind duplicates; one field blank per day; one travel blank per shipment. For each sample collection personnel use new latex or Nitrile gloves for collecting each sample and augers and shovels are washed to avoid potential cross contamination. At the time of sampling, on-site activities and observations are documented including field testing results, soil pile stability or suspected leachate issues.

Upon receipt, the laboratory conducts internal QA/QC sampling. If results from either field or lab QA/QC analysis are considered significantly different, re-sampling will occur.

d) Soil Reuse and Disposal

Once remediated soil has been analysed, it is classified as either meeting reuse criteria, requiring additional treatment or requiring off-site disposal. Soil suitable for industrial reuse has analytical results meeting the criteria outlined in Appendix A. Material meeting re-use criteria will be used as cover material at the Hamlet's landfill or re-purposed as permitted.

Soil is removed from the cell using an excavator and dump truck and is hauled to the landfill working face. If it is determined that soil for which no acceptance analytical was collected is untreatable or unacceptable at the facility, it will be managed in the same way as soil that needs to have final disposal at an alternate approved facility.

All materials removed from site will be accompanied by appropriate movement documents. Volumes and soil sampling results will be provided in annual reports distributed to DOE, INAC and the Nunavut Water Board (NWB).

e) Maintenance

Weekly site inspections during snow-free months include a visual inspection for erosion, subsidence, exposure of liner, leakage, wildlife disturbance and security breach. During winter months, inspections occur monthly. The Soil Treatment facility liner is inspected annually, after soil turning and soil removal. Any tears detected during visual inspection will be repaired and documented immediately. Inspections are conducted by trained personnel. Inspection logs are maintained on site will be provided upon request. An example of the inspection form can be found in Appendix D.

f) Water/Snow Storage Pond

The water storage area will be 19m x 14m lined pond located in the corner of the treatment pad or constructed as stand-alone pond located adjacent to the treatment pad. An engineered pond is utilized to accept petroleum hydrocarbon-contaminated water and snow from off-site sources including residential, commercial and industrial properties where a petroleum hydrocarbon spill or leak has occurred. Snow and water transported to site requires confirmation of contaminants of concern from the spill source, MSDS and/or results of analytical testing and a suitable movement document prior to receipt on site. It is not anticipated that the facility will receive water or snow contaminated with anything other than petroleum hydrocarbons. The capacity of the retention pond is anticipated to be 170m³.

Water will be transported to town using a dedicated pumper truck and disposal into the pond will be done by hose. Snow that is delivered to the site will be placed into the pond by dump truck or loader. Care will be taken to ensure that snow does not spill over the berms of the pond. If required, an excavator will be used to knock down larger piles and level out any snow that has

been piled. Care will be taken to ensure that any contaminated snow is not tracked out of the facility by scraping tracks clear of any contaminated snow that it contacted.

An above ground storage tank (AST) or a vacuum truck will be used onsite in the event that water levels are anticipated to increase beyond the storage capacity of the pond. Regularly scheduled site inspections during snow free months will monitor the water levels, exposure of liner, and retention pond volumes. Inspection logs will be maintained onsite at all times.

As water levels increase in the retention pond, samples will be collected and analyzed for the parameters listed on Table A3 in Appendix A. If the samples do not meet the guidelines, the water from the storage pond will be treated using an onsite water treatment plant and transferred to a storage tank onsite. Once results are received and meet the guidelines set forth by the issued license, the water will be discharged to surface. Analytical results and notification will be reported to the DOE and INAC prior to the planned discharge. In the event that water does not meet discharge criteria it will undergo further treatment or be transported to an authorized disposal location.

g) Water Treatment Plant

The mobile water treatment plant consists of a series of inline bag filters designed to remove sediment and suspended solids. Following the filter bag train, effluent enters the bottom of treatment vessels which contain granular activated carbon and an organoclay. Water treatment is designed to occur in a manner to promote contact between the effluent and the media, enhancing treatment success. Treated water would be stored in ASTs and sampled for comparison against the parameters outlined in the license. Performance of the treatment system is dependent on the contaminant. Organic contaminants are likely to be removed easily from the water. Inorganic constituents have been successfully removed by activated carbon and organoclay filtration, however less reliably so. Sampling prior to, and after discharge will be required in order to determine treatment efficacy. Additional media may be obtained for treatment of specific contaminants of concern. Once it is confirmed that water meets the guidelines set forth by GN and NWB in the license, representatives from DOE and INAC will be provided with analytical water quality results. 10 days prior to discharge, disposal or reuse of water from the ASTs or retention pond notice of intent to discharge will be given.

Once it is confirmed that water meets the applicable guidelines, it will be discharged to surface in a manner which follows natural site drainage and avoids erosion. If it is determined that erosion is occurring, a splash pad will be constructed using riprap. The details and design will be discussed with stakeholders prior to construction. All discharged water and groundwater will respect Section 36(3) of the Fisheries Act (EC, 1985) year round, ensuring that at "no person shall deposit of deleterious substance of any type in water frequented by fish". Discharging will be documented and submitted in the annual report.

h) Water Monitoring Program

In addition to visual inspections, a groundwater monitoring program (GMP) will be in effect to detect any changes in groundwater quality. The GMP will include annual monitoring and sampling of the groundwater wells (locations to be determined prior to construction). Groundwater wells will be analyzed and compared to the Federal Interim Groundwater Quality Guidelines (Environment Canada, 2012). Results from the monitoring and sampling events will be issued in the annual report along with accompanying laboratory certificates of analysis.

i) Wind Erosion Mitigation

Strong winds can carry soil from stockpiles to areas outside the soil storage area. A contingency plan is required to mitigate soil erosion and the potential spread of contaminants. The main factors influencing wind erosion from soil stockpiles are the threshold wind speed, stockpile contents and surrounding conditions.

Wind erosion can be effectively controlled through maintaining moisture content within soil piles. Moisture is also an important factor in the bioremediation process therefore it is necessary to maintain adequate moisture content for microbial activity. Wind erosion control through moisture control will be satisfied by topical applications of water from the retention pond. As required, water from the pond will be sprayed over the soil stockpiles at a rate sufficient enough to minimize erosion by wind and minimal enough so as not to create ponding within the storage area.

If wind conditions are such that substantial dust is created during soil handling and treatment, activities will be shut down until conditions stabilize. Where possible, operations may shift to another area within the facility that is more sheltered.

To ensure that snow in the water/snow storage pond is not susceptible to being wind swept, a snow fence will be erected surrounding the pond. This will serve to decrease the effects of wind on the pond and its contents, along with serving as a barrier to people and animals.

j) Containment of Impacted Soil

Equipment working in and around the biotreatment pad presents a risk of spreading contaminated material from machinery tracks or tires as equipment is moving at the edges of the biotreatment pad or when soil is being handled for discharge. In addition, other conditions may also result in soil moving beyond the biotreatment pad such as unstable piles and inadequate soil berms. In order to minimize the spread of impacted soil, the following measure will be implemented:

- Operators of track mounted equipment working in the biotreatment pad will be required to shovel/remove soil off the tracks prior to leaving the area.
- 2. Trucks delivering contaminated soil to the Facility will be required to use a spotter or other indicator to ensure they are not back into the treatment pad further than necessary.
- 3. Soil piles and windrows should be stably built with piles at or near the angle of repose.

- 4. Soil berms should be high enough and at an adequate distance to prevent soil which has rolled off piles from leaving the biotreatment pad.
- 5. Any soil tracked or dropped outside the treatment cell will be immediately scraped up and put back into the biotreatment pad.

k) Hazardous Waste Storage Area

A portion of the bermed and lined soil treatment pad will be used for the storage of hazardous waste containers (drums, bags etc.) that are awaiting transportation to authorized facilities. These types of waste could include fuels, oils, solvents and glycols which require consolidation, containerization and temporary storage onsite while awaiting shipment to authorized facilities. Used water treatment plant media or used spill response items may also be stored at this location awaiting final disposal.

4.0 Documentation and Reporting

A daily log of acitivites will be kept detailing personnel onsite, acitivities undertaken, weather conditions and water pond freeboard. Monthly inspections will be conducted and documented. An annual report will be submitted to the Nunavut Water Board (NWB) and all stakeholders in accordance with the terms and conditions of the license approval and permits assigned to the Facility. In conjunction with annual reporting, this Plan is to be reviewed annually and updated as needed to maintain compliance. Analytical test results, as required under the anticipated water license, are submitted to DOE and INAC in a timely manner. A copy of all licenses and permits will be maintained on site.

5.0 Safety and Emergency Response

The operations at the facility will involve the use of heavy equipment to process the soil stored for treatment and for the movement of soil into and out of the treatment pad. The soils handled at site have varying levels of petroleum hydrocarbon contamination.

All operations will be performed in conjunction with KEL Health and Safety Programs and applicable regulations and standards. All personnel on site are required to wear basic personal protective equipment: hard hat, high visibility vest or striping, safety footwear. Other PPE requirements are specific to the tasks undertaken by the employees on site. Refer to the KEL Health and Safety Manual (which will be available on site).

Emergency Contact Information for the Cambridge Bay Soil Treatment Facility:

Police 867-983-1111

Fire 867-983-2222

Ambulance 867-983-2531

KEL 867-983-7500

Hamlet of Cambridge Bay 867-983-4650

Department of Environment 867-975-7700

a) Fire and Prevention Control

The purpose of this plan in to provide information to KEL employees and contractors in the event that a fire occurs at or near the facility. Specifically, the plan establishes who is responsible for various aspects of the fire control procedure.

DO NOT PANIC, the greatest danger lies not in fighting the fire, but in the panic that arises from a fire. Spend a few minutes getting a grip of the situation. Go through the steps of notifying the appropriate authorities and follow the basic steps in the fire control plan.

- 1. Notify any other nearby employees.
- 2. Notify the site manger immediately. Follow his instructions.
- 3. Notify the fire department. Tell them the location and type of fire and whether it looks like it will spread out of the immediate area.
- 4. Notify surrounding property owners, particularly if it appears that the fire could spread beyond the facility.
- 5. When the fire department arrives, follow their instructions.
- 6. Do not fight the fire alone.
- 7. Do not place yourself or others in danger while fighting the fire.

b) Spill Response Plan

For the purpose of this plan, a spill is the accidental or purposeful discharge of a liquid waste (listed herein) or contaminated soil in a location or manner that will allow it being washed, carried, or flow into a natural or man-made watercourse that could potentially result in groundwater or surface water contamination now or in the future.

Most potential spill sources will only be present during normal facility working hours. As a result, adequate personnel and equipment is available to respond to any spill-related emergency. With equipment at the facility, it is possible to respond immediately to the site of any spill for necessary spill containment and cleanup. The immediate requirement will be to construct temporary earth berms around the spill area to control and allow implement cleanup measures as directed by the Site Manager and the Hazardous Materials Response Team (if applicable).

The facility is operated in conjunction with KEL's Spill Contingency Plan (KEL 2017) along with KEL's Waste Management Plan (KEL 2017). The Spill Contingency Plan addresses spills of:

- 1. Fuel and oils from operating equipment.
- 2. Soils contaminated with petroleum hydrocarbons.
- 3. Liquids from the storage pond.

6.0 Training

Personnel managing waste are certified in Workplace Hazardous Material Information System (WHMIS) and Transportation of Dangerous Goods (TDG). Any waste shipment requiring a Federal Movement Document (FMD) will need to have FMD filled out by an individual holding a valid certificate in TDG. Personnel responsible for operation and maintenance of the SWTF will receive training in the principles of soil treatment along with safe operating procedures.

7.0 Facility Closure

Final closure of the facility will involve the decommissioning of the lined bioremediation cell, the lined water pond and the removing of all fencing and security installations associated with the site. The used liners will be disposed of at the hamlet landfill and the site will be regraded back to natural drainage. Long term monitoring will continue once the facility has been decommissioned and prior to any future use for the land. No long term effects are anticipated following facility decommissioning.

Standard Operating Procedure

Soil Sampling and Handling at STFs

Pre-Acceptance and Re-Use Sampling Protocol

Standard Operating Procedure Soil Sampling and Handling at STFs

Objective:

This protocol is intended for use at KEL soil treatment facilities in order to determine whether treated soils meet landfill cover criteria. Soil treatment facilities each have criteria specific to the facility. Soil samples will be obtained using the protocol below and then compared to the criteria to determine if the soil may me moved off of the treatment pad. This protocol does not apply to sampling of clean fill for use on third party sites.

Protocol:

The soil arriving at the facility will be segregated according to source site. Each source site will be assigned a project number prior to arriving at the facility. The soil from each project will remain segregated while on the treatment pad.

 The number of composite samples required will depend on the volume of soil for each project. Composite sample will represent 50 to 1000 m³ of soil in accordance with the following table:

Volume of Soil Project (m³)	Composite Samples Required
1-50	1
51-500	2
501-1000	3
1001-2000	4
2001-5000	5
Each additional 1000 over 5000	+1

- Composite samples will consist of a minimum of five subsamples obtained at different vertical depths in the same horizontal location;
- Samples are identified by PROJECT-SAMPLE-DATE i.e., 15-002-01-150812;
- Diagrams of the treated soil piles are sketched and/or GPS data is collected showing the exact location of each soil pile represented by a composite sample;
- Samples are taken using a hand held auger or if required, an excavator should be used to ensure that the entire vertical profile of the lot is represented by the sample;
- Information required for sampling diagrams includes:
 - Facility Name;
 - Sample Date;
 - Sampled By; and
 - Comments (if any).
- All field staff are required to wear PPE during sampling events including but not limited to safety glasses, hard hats, steel toed boats, safety coveralls and gloves;

Standard Operating Procedure Soil Sampling and Handling at STFs

- Each composite sample is tested for BTEX/F1-F4, and CCME metals at a minimum, other parameters or contaminants of concern may be required based on the facility or the generating location;
- If necessary, resampling will occur after an additional treatment campaign for confirmation;
- No Headspace: Sample jars will be filled with soil to the top. That is, there should be no void spaces in the jars after sampling;
- Duplicate samples will be collected at a rate of one duplicate per 10 samples with a minimum of one duplicate per sampling event. The relative percent difference (RPD) will be calculated on duplicate sample results by the following formula:

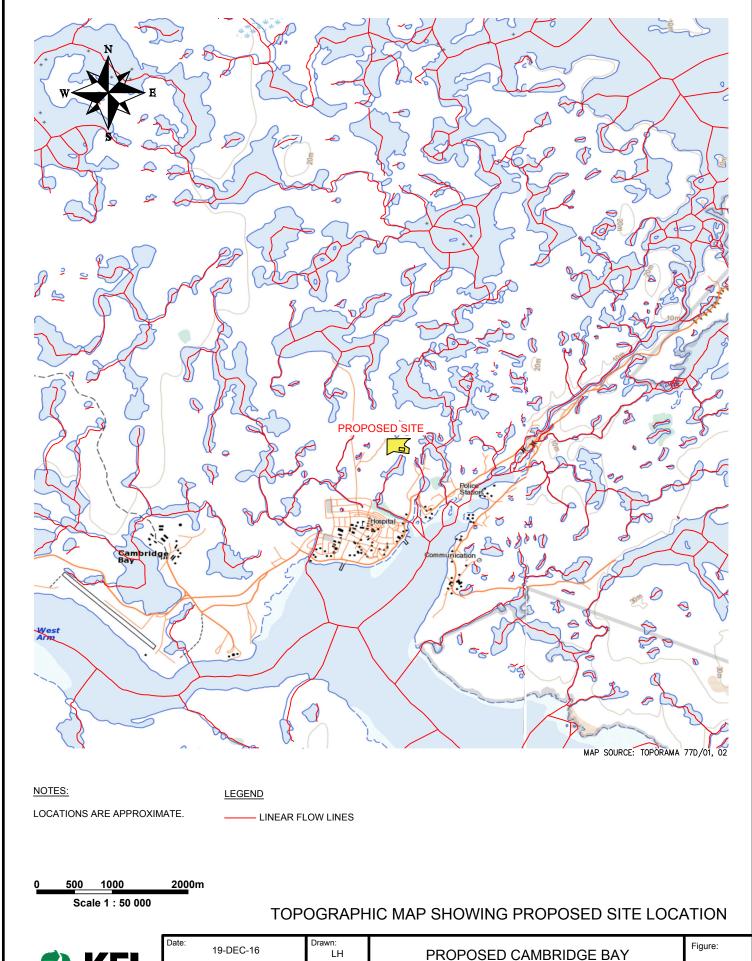

$$RPD\% = \left| \frac{(C1 - C2)}{\left[\frac{C1 + C2}{2} \right]} \right| \times 100\%$$

- Analytical data is reviewed and tabulated in an excel spreadsheet for review;
- Soil analysis must be reviewed by two qualified staff prior to removal from the pad.
 Only soils meeting license criteria, GNWT/Federal regulations for industrial use will be reused as alternative daily cover (ADC) once approved; and
- Treated soil meeting ADC may be stockpiled off the pad.
