APPENDIX A: PROOF OF LABORATORY ACCREDITATION	

1. Introduction

During the clean-up of the CAM-4 DEW Line site at Pelly Bay, Nunavut the collection of sewage effluent samples will only be required should the construction camp discontinue the practice of having its sewage collected and treated by the Hamlet of Kugaaruk Municipal Services.

If an on-site Sewage Disposal Facility is constructed and used, the Proposed Monitoring Program for CAM-4 states that the contents of this facility shall be analyzed once at 30 days after its establishment and a second time prior to discharge. All waste discharged from this Facility will be analyzed for the following parameters:

- Mineral oil and grease (observations of presence/absence of sheen will be made – no samples will be collected or analyzed);
- Total suspended solids (TSS);
- Biological oxygen demand (BOD₅);
- Faecal coliforms; and
- pH.

2. Sample Collection

2.1. Location

GPS coordinates of sample locations are collected and recorded. Photographs of the sample location are also taken.

2.2. Sampling Equipment

The following table summarizes the equipment and storage requirements for each water sample type collected. New bottles were used in all cases for the collection of the water samples.

Contaminant	Container	Amount	Rinse	Storage	Special Treatment
TSS, pH	1L Plastic Bottle	Full	No	Cool	Do not filter
BOD ₅	250 mL amber glass bottle	Full – no headspace	No	Cool	Do not filter
Bacteria and coliforms	Bacti bottles (Accutest)	Full	No	Cool	Analyze within 48 hours of collection

2.3. Sampling Methods

Sample bottles will be filled completely at the time of sampling. Bottles are not to be filled progressively over the course of days. If there is not sufficient water to completely fill the bottle(s), then no water sample will be collected. The bottles are to be filled with no headspace remaining to guard against volatilization of dissolved phases. Generally, the samples will be collected immediately prior to departure from the site and submitted for analysis within 48 hours.

3. Sample Handling

3.1. Preservation

The water samples will be kept cool (approximately 4⁰ C) prior to and during shipping. In general, water samples will be collected when transportation from the site will be available almost immediately after, as many types of the required analyses should be performed as quickly as possible after collection.

Ideally, samples collected for inorganic analyses should be acidified in the field, at the time of collection. However, regulations concerning the transportation of dangerous goods make supplying concentrated nitric acid in the field difficult. Where samples cannot be acidified in the field, it will be requested that the samples are acidified immediately upon receipt in the lab, *prior* to decanting or sample extraction. When acidifying in the lab, the container will be rinsed with 35% HNO₃ and included with the sample.

Samples are not to be filtered at any time. If samples contain excessive sediment, the samples will simply be decanted in the southern laboratory (*following* acidification, for metal analyses) prior to analysis.

3.2. Sample Identification

Each water sample will be given a blind number that was the only number provided on the labels of samples submitted for analysis. This sample number corresponds to the number assigned to that specific sample location which will be recorded on a map and in the field notebook.

3.3. Transportation

Samples are to be shipped by guaranteed airfreight in coolers from the site to their respective accredited laboratory for analysis. Chain-of-custody forms will be filled out and checked for each sample before shipment from the North, and the contents of shipments will be verified upon receipt in the laboratory.

4. Lab Analysis

4.1. Lab Accreditation

All laboratory analysis is carried out at accredited labs. The following laboratories are the ones primarily responsible for the analysis of water samples collected at CAM-4 (Pelly Bay):

- 1) Analytical Services Unit, Queen's University, Kingston ON; and
- 2) Analytical Sciences Group, Royal Military College of Canada, Kingston ON.

Proof of accreditation from these laboratories is located in Appendix A. The standard methods used by the laboratories for each of these analyses are listed in the laboratory's scope of accreditation.

4.2. Detection Limits

The following table provides a summary of the detection limits for the analysis to be performed on water samples collected at CAM-4 (Pelly Bay).

Parameter	Detection Limit
Biological oxygen demand (BOD ₅)	3 mg/L
Total suspended solids (TSS)	1 mg/L
Faecal coliforms	0 counts/100 mL

4.3. Methodology

The following is a summary of the methods to be used in the analysis of the water samples collected from CAM-4 (Pelly Bay).

4.3.1. *Total Suspended Solids*

Analyses were conducted by the Analytical Services Group, Royal Military College, Kingston, Ontario. Each sample was clearly labelled and stored at low temperatures in a secured area before and after analysis.

Total suspended solids (TSS) in water were determined by filtering a sample through a 0.45-micron glass fibre filter. The filter was first dried in an oven at 105 °C for 4 hours, allowed to cool, and weighed. A measured volume of water (usually 500 mL) was poured through the filter, which was then oven-dried for 12-18 hours, cooled, and reweighed. The TSS were reported as the weight of suspended material divided by the volume of water (units of mg/L).

4.3.2. *Biological Oxygen Demand (BOD₅)*

Analyses were conducted by the Analytical Services Group, Royal Military College, Kingston, Ontario. Each sample was clearly labeled and stored at low temperatures in a secured area before and after analysis.

The dissolved O₂ consumed over a five-day period was used as a measure of organic matter oxidizable by biological means. Nutrients were added to each sample solution. Dissolved oxygen was determined using a probe while stirring each solution. Samples were diluted if necessary. The difference in the dissolved oxygen measured in a sample upon receipt and after five days was taken as the measure of its biological oxygen demand (BOD).

4.3.3. *Analysis of Faecal Coliforms in Water*

Analyses were conducted by the Analytical Services Group, Royal Military College, Kingston, Ontario. Each sample was tested for storage temperature and checked for holding time in receipt. All samples were clearly labeled and stored at low temperatures in a secured area before and after analysis. Drinking water analyses were conducted in accordance with Canadian Drinking Water Quality Guidelines and according to procedures appropriate to Ontario Reg. 169/03 (Safe Drinking Water Act, 2002).

A vacuum filtration apparatus was used to filter 100 mL of sample onto a 47 mm diameter, 0.45 μm pore size cellulose ester membrane filter. The membrane filter was then placed on a fecal coliform (FC) agar plate and incubated at 44.5 ± 0.2 °C for 24 ± 2 hours. After the incubation period, fecal coliform colony-forming units (CFU) appeared as blue colonies on the membrane filter.

The presence of any fecal coliform bacteria per 100 mL in drinking water samples is considered adverse (Table 1, Microbiological Standards of Technical Support Document for Ontario Drinking Water Standards, Objectives and Guidelines (MOE 2003) according to the Safe Drinking Water Act O. Reg. 169/03. Coliforms are not necessarily pathogenic, but the presence of coliforms in water samples, especially *E. coli*, is indicative of recent fecal contamination and hence the possibility of contamination by the pathogenic organisms commonly associated with fecal waste.

4.3.4. pH Measurement

Measurements on water and soil samples were conducted by the Analytical Services Group, Royal Military College, Kingston, Ontario.

Water samples were measured directly using a 50-mL sample; the pH of soil was determined by mixing 10 g of soil with 10 mL of distilled water, allowing the mixture to settle, and measuring the pH of the supernatant. The pH was measured with a Denver Instruments model 220/300729.1 pH meter and probe, relative to buffered reference standards and control.

4.4. Reporting Requirements

The following types of QA/QC samples will also be collected as part of the water sampling program. Note that if more than one type of bottle is used for each water sample, QA/QC samples will be submitted in each type of bottle used for the collection of the samples.

Field duplicates: Approximately 10% of the samples were collected as field duplicates. That is, two samples were collected from one sample location. These samples were handled in the same way and submitted blindly to the laboratories for analysis.

Field blanks: Field blanks consisted of distilled water and were collected to ensure that there is no corruption of samples from the sampling method. The distilled water was

poured from its container into the sample container at the same time and using the same techniques as used to collect the regular water samples.

Travel blanks: The purpose of travel blanks is to ensure that there is no corruption of the sample or sample container during travel. Ideally, a full set of travel blanks should accompany each shipment of water samples. However, in cases where very few samples are shipped at a time, this guideline can be extended to a more reasonable number. Travel blanks were filled at ESG prior to leaving for the field. They were shipped with the sample bottles, stored with the sample bottles on site, brought out to the sampling location in the field, returned to the lab, and shipped to the labs with the water samples. They should not be opened unless the other bottles or water samples are opened for some reason during shipping.

Revised CAM-4 QA/QC Plan
