Hope Bay Project: Boston Surface Infrastructure
Preliminary Design

Memo

To:	John Roberts, PEng, Vice President Environment Oliver Curran, MSc, Director Environmental Affairs	Client:	TMAC Resources Inc.
From:	Cameron Hore, CPEng, PEng Megan Miller, PEng	Project No:	1CT022.013
Reviewed By:	Maritz Rykaart, PhD, PEng	Date:	November 30, 2017
Subject:	Hope Bay Project: Boston Surface Infrastructure Preliminary Design		

Change Log

The following table provides an overview of material changes to this report from the previous version issued as Appendix V3-3J as part of the DEIS for Phase 2 of the Hope Bay Project dated December 2016.

Changes by Section

Information Request, Technical Comment, or Other Change	Section	Comments
Other	4.2	Contact water ponds now addressed in separate report (SRK 2017c)
Other	2.2, 4.1.1, Attachment 2	Increase in select infrastructure footprints to accommodate doré production.
Other	4.8	Inclusion of explosives facility in Quarry V
Other	4.7	Additional fuel storage capacity
INAC-IR2 (a)	2.2	Inclusion of incinerator in Table 2.1
INAC-IR4	4.5.2	Additional details on landfill design included
KIA-IR176 (1)	4.1.1	Clarification of overall slope angle
KIA-IR176 (2)	4.5.2	Additional details on landfill cover included
Other	4.9	New section, providing details on reagent facility required to store reagents for doré production

1 Introduction

1.1 General

The Hope Bay Project (the Project) is a gold mining and milling undertaking of TMAC Resources Inc. The Project is located 705 km northeast of Yellowknife and 153 km southwest of Cambridge Bay in Nunavut Territory, and is situated east of Bathurst Inlet. The Project comprises of three distinct areas of known mineralization plus extensive exploration potential and targets. The three areas that host mineral resources are Doris, Madrid, and Boston.

The Project consists of two phases: Phase 1 (Doris project), which is currently being carried out under an existing Water Licence, and Phase 2 (Madrid-Boston project) which is in the environmental assessment and regulatory stage. Phase 1 includes mining and infrastructure at Doris, while Phase 2 includes mining and infrastructure at Madrid and Boston located approximately 10 and 60 km due south from Doris, respectively. Boston will be a standalone self-contained mining complex complete with all surface infrastructure to support mining and ore processing required to produce doré.

1.2 Objectives

This memo provides preliminary engineering design details of the Boston surface infrastructure, excluding the tailings management area (SRK 2017a), the airstrip (SRK 2017b), the contact water ponds (SRK 2017c) and the Madrid-Boston all-weather road (SRK 2017d).

2 Design Concept

2.1 Approach

Boston is a self-contained mining complex, and thus contains all surface infrastructure required to support the mining operations, including a camp and ore processing facility.

The overall design concepts for the Boston surface infrastructure (i.e. pads, roads and water management facilities) are based on the same principles as used for Doris. As far as practical, all facilities will be constructed either on bedrock, or geochemically suitable rock fill pads designed to protect the permafrost. Site layouts are designed to minimize the overall footprint, and minimize the volume of contact water that has to be captured and managed via ponds for appropriate disposal.

Access roads are considered private roads, administered and controlled entirely by TMAC. TMAC has opted to design all site roads to mine haul road standards as set out in the Nunavut Mine Health and Safety Act (WSCC 2015).

2.2 Infrastructure Components

The surface infrastructure associated with the mining activities at Boston include necessary access roads, water management facilities and pads to support buildings associated with accommodations, processing and other mining support services. These components along with limitations on their location are summarized in Table 2.1. Infrastructure components have been grouped into zones with the understanding that these components should be grouped together for functionality.

Table 2.1: Summary of Infrastructure Associated with Boston

Zone	Infrastructure Component	Surface Area	Limitations and Comments
Camp	Camp	10,224 m ² (71 x 144 m)	Minimum 10 m offset from other buildings; Connected to processing and mine zone buildings via arctic corridors
	Sewage Treatment Plant	30 m ² (6.1 x 4.9 m)	Minimum 10 m offset from other buildings; Downwind of the camp
	Potable Water Treatment Plant	45 m ² (6.1 x 7.3 m)	Minimum 10 m offset from other buildings
	Fire Water Tank	79 m ² (10 m diameter)	Minimum 10 m offset from buildings
Geology	Heliport	729 m ² (27 x 27 m)	Requires 27 m clearance distance from all buildings
	Heliport Shack	15 m ² (6.1 x 2.4 m)	Shack at edge of 27 m heliport clearance
	Exploration Office	250 m ² (15 x 10 m)	Minimum 10 m offset from other buildings
	Core Shack	325 m ³ (25 x 13 m)	Minimum 10 m offset from other buildings
	Core Storage	10,000 m ²	General outside storage
Processing	Power Station	1,250 m ² (50 x 25 m)	Minimum 10 m offset from other buildings; Requires bedrock, or piled foundation
	Process Plant Office	144 m ² (12 x 12 m)	Minimum 10 m offset from other buildings; Connected to camp and mine zone buildings via arctic corridors; Near power station to maximize heat recovery opportunity
	Water Treatment Plant	30 m ² (6.1 x 4.9 m)	For treatment of process and contact water; Minimum 10 m offset from other buildings, or inside processing plant
	Ore Pad (and Associated Ore Stockpile)	2,400 m ²	Haul distance of less than 500 m from portal preferred; Haul road grade cannot exceed 7%; Two ore stockpiles, each with a minimum ore storage capacity of 20,000 tonnes (11,100 m ³) Expected operational Ore Stockpile tonnage is 8,000 tonnes (4,400 m ³). Must drain towards a contact water pond
	Warehouse	1000 m ² (50 x 20 m)	Minimum 10 m offset from other buildings
	Processing Plant	14,000 m ²	Minimum 10 m offset from other buildings; Requires bedrock, or piled foundation; Connected to camp and mine zone buildings via arctic corridors; Near power station to maximize heat recovery opportunity

Zone	Infrastructure Component	Surface Area	Limitations and Comments
	Reagent Storage	15 m ² (6.1 x 2.4 m)	Can be immediately adjacent to or inside the processing plant building
	Emergency Response Center	144 m ² (12 x 12 m)	Minimum 10 m offset from other buildings. Near process plant.
Mine	Portal Access Clearance	36 m ² (6 x 6 m)	-
	Vent Raise	625 m ² (25 x 25 m)	-
	Mine Office	300 m ² (12 x 25 m)	Minimum 10 m offset from other buildings; Connected to camp and mine zone buildings via arctic corridors; Near power station to maximize heat recovery opportunity
	Mine Dry	600 m ² (30 x 20 m)	
	Mobile Equipment Workshop	600 m ² (30 x 20 m)	
	Waste Rock Pad (and associated waste rock pile)	As required for 349,000 m ³	Haul distance of less than 500 m from portal; Haul road grade cannot exceed 7%; Minimum storage of 628,000 tonnes (349,000 m ³); Should drain to a contact water pond
Other	Water Supply Pump House	15 m ² (6.1 x 2.4 m)	Minimum 10 m offset from other buildings
	Landfarm	4,725 m ² (105 x 45 m)	Minimum 10 m offset from buildings
	Reagent Facility	4,125 m ² (75 x 55 m)	Minimum 10 m offset from buildings
	Incinerator	15 m ² (6x2.5 m)	Minimum 10 m offset from buildings
	Non-Hazardous Landfill	50,000 m ²	Located within a quarry, more than 450 m from camp, but less than 10 km from the mine
	Fuel Storage Facility	9,900 m ² (165 x 60 m)	Minimum 10 m offset from buildings; Requires bedrock, or piled foundation
	Laydown Areas	36,000 m ²	General outside storage area for equipment and supplies
	Overburden Pile	As required for 54,100 m ³	Minimum storage of 54,100 m ³ ; Should drain to a sedimentation pond
	Contact Water Pond(s)	As required	Needed downstream of ore, waste rock and processing pads
	Explosives facility	35,000 m ² (700 x 50 m)	Based on separation distances between individual facilities as defined by NRCan 2007.

2.3 Foundation Conditions

Numerous geotechnical investigations have been performed at the Project site. A surficial geology and permafrost investigation was carried out at Boston in 1996 (EBA 1996).

The investigation included air photo interpretation followed by ground truthing and completion of six onshore drill holes, followed up by laboratory testing of select geotechnical samples.

The investigation found the proposed Boston area is characterized mostly by marine deposits of silty-clay with trace sand. With small pockets of glaciofluvial deposits of coarse sand and some gravel.

Project-wide overburden consists of permafrost soils which are mainly marine clays, silty clay, and clayey silt, with pockets of moraine till underlying these deposits. The marine silts and clays contain ground ice ranging from 10 to 30% by volume on average, but occasionally as high as 50%. The till typically contains low to moderate ice contents ranging from 5 to 25%. Overburden soil pore water is typically saline due to past inundation of the land by seawater following deglaciation of the Project area. Salinity measurements in the EBA (1996) investigation ranged from 3 to 48 parts per thousand, which depresses the freezing point and contributes to higher unfrozen water content at below freezing temperatures.

Permafrost at the Project area extends to depths of about 565 m, with an average geothermal gradient of 0.021°C/m. Active layer depth in overburden soil averages 0.9 m, with a range from 0.5 to 1.4 m (SRK 2017e).

Isopach maps developed from seismic surveys and exploration and geotechnical drill holes indicate that depth of overburden under the infrastructure is expected to range from 0 to 10 m, with most areas having less than 6 m of overburden. The closest geotechnical drill holes (EBA-12259-02 and EBA-12259-03) indicate that the overburden under the infrastructure pads is likely silts, clays, and sands. Ice content of the foundation soils could also be in the higher end of those typically found on the Project, as those drill holes note ice contents up to 70% (EBA 1996).

General foundation conditions, material properties for geotechnical analysis, and development of the overburden isopach surface are described in more detail in SRK's Geotechnical Report (2017e).

2.4 Environmental Setbacks

The following environmental setbacks have been applied when selecting the location of the infrastructure:

- Minimum 31 m setback from waterbodies, 50 m setback where possible;
- Minimum 30 m buffer zone from known rare plants; and
- Minimum 30 m buffer zone from known archeological sites.

While priority was given to avoid these areas, in some cases the minimum buffer around archeological sites and rare plants could not be maintained. In these instances, the archeological site will be mitigated in accordance with the Heritage Resources Protection Plan (TMAC 2016).

3 Alternatives

3.1 Overall Site Layout

Alternative layouts were prepared primarily based on watershed areas, overburden thickness, and a 50 m crown pillar based on the current and future mine development. Components that take priority in developing alternate site layouts are the processing plant, the power plant, and the fuel storage facility, as these facilities should be constructed on a competent foundation, ideally bedrock, and outside of the 50 m crown pillar offset. Since the Boston area has limited exposed bedrock, areas where bedrock is less than 3 m deep was deemed suitable as excavation of this amount of overburden would be practical.

A second priority in evaluating site layout alternatives was to minimize the amount of affected watersheds. To that end the areas where contact water may be impacted by operations, such as the mine and processing zones, was grouped to minimize the footprint and affect the minimum amount of watersheds such that contact water ponds can be minimized and reduced in size.

Components in the camp zone should be relatively close to the mine and processing zone infrastructure, while the geology zone, landfarm, landfill, overburden storage area, and laydown areas were assumed to be the least critical infrastructure in terms of limitations on placement. Table 3.1 lists the three general site layouts that were considered (Figures 1 to 3). Alternative 3 is preferred as it is the most functional of the options, has the required space for all infrastructure, and has the most favourable foundation conditions.

Table 3.1: Alternative Infrastructure Locations

Alternative	Details
1	The camp and geology zone buildings would be located ~200 m north of the current portal. The mine and processing infrastructure would be placed ~50 m east of the portal, close to the planned waste rock pile. Laydown areas, fuel facility, and the landfarm would be placed ~700 m south of the portal. The advantages of this layout are the short haul distances between the portal and the processing, the nearness of the camp to the mine and processing infrastructure, and that contact water from the mine and process plant are contained within the same contact water pond as the waste rock pile. The disadvantage of this layout is that there are three distinct separated areas.
2	The camp and geology zone buildings would be located ~200 m north of the current portal. The mine and processing infrastructure as well as the infrastructure within the other zone would be placed ~700 m south of the portal. The advantage of this layout is that the camp is located close to the portal. The disadvantage of this layout is that the mine and processing infrastructure are far from the camp and portal.
3	All infrastructure excluding the waste rock pile and overburden pile would be located ~700 m south of the portal. The majority of the infrastructure is contained within one location. There is greater access to areas with shallow bedrock and increased space for access roads and pads. There is a relatively long distance from the process plant and the addition of a second ore storage pile is required.

4 System Design

4.1 Waste Rock, Ore Stockpiles and Overburden Pile

4.1.1 Design Criteria

The waste rock pile is expected to be a temporary stockpile and, prior to closure, all waste rock will be hauled for underground stabilization. However, the waste rock pile will be designed for the maximum volume of waste rock expected to be brought to surface from the Boston Mine. During construction of the infrastructure pads for the processing and mine zone components, some overburden may have to be removed to expose bedrock. Since this material may not be suitable for use as mine backfill, a permanent storage area for this material is required. The design criteria for the waste rock storage area, ore stockpile and overburden pile are as follows:

- Minimum waste rock storage capacity of 628,000 tonnes (349,000 m³);
- Two ore stockpiles, each with a minimum ore storage capacity of 20,000 tonnes (11,100 m³);
- Minimum overburden storage capacity of 37,000 m³;
- Maximum overall slope angle for waste rock and ore of 2.5H:1V (21.8°) as measured from the toe of the lowest bench to the set-back of the highest bench, assuming inter-bench angle of repose slopes of 1.3H:1V (37°), bench heights of 5 m and bench widths of 6 m. Minimum slope angle of 5H:1V (11°) for overburden;
- Maximum height of 100 m for waste rock and ore, and 5 m for overburden;
- Factors of safety (FOS) as defined in the Mined Rock and Overburden Piles Interim Guidelines (Piteau 1991) of:
 - 1.0 for pile surface during construction;
 - 1.3 for short and long term deep seated stability; and
 - 1.1 for pseudo-static deep-seated stability.
- Seismic parameters, as defined in the Mined Rock and Overburden Piles Interim Guidelines (Piteau 1991) for an event with a 10% probability of exceedance in 50 years (1:500 year return period); and
- Design vehicle for the ore and waste rock piles is a loaded Sandvik TH540 (40 tonne) haul truck.

4.1.2 Design

The Boston waste rock pile has a maximum available capacity of 349,000 m³ (628,000 tonnes), and a maximum height of approximately 23 m. The waste rock pile is located on a 1 m thick geochemically suitable run-of-quarry (ROQ) or run-of-mine (ROM) material pad.

The Boston waste rock pile has a pile stability rating of LOW according to the classification standards outlined by the Mined Rock and Overburden Piles Interim Guidelines (Piteau 1991). This rating is due to the shallow foundation slopes, low seismicity, side hill design, thin lifts, and slow dumping rate (Attachment 1).

The Boston overburden pile has a maximum available capacity of 37,000 m³ and a maximum height of approximately 5 m. The overburden pile is located on a 1 m thick ROQ or geochemically suitable ROM material pad. The pile is located within the Stickleback Lake watershed and the Madrid-Boston all-weather road will act as a sedimentation berm for the overburden pile, by allowing water to slowly filter through the road and depositing entrained sediments.

Stability analysis performed on a general waste rock pile on site indicates that a waste rock pile designed to the design criteria listed above should be stable under static and pseudo-static conditions. Details of the stability analysis including material properties and seismic parameters used in this assessment are described in SRK (2017e).

4.2 Contact Water Ponds

There will be two unlined contact water ponds and one lined surge pond at Boston. These ponds will be located downstream of the waste rock pile, ore stockpiles, camp, mine and processing infrastructure.

The design criteria and design of the contact water ponds and surge pond are provided in the Boston Water Management Engineering Report (SRK 2017c).

4.3 Infrastructure Pads

4.3.1 Design Criteria

The design criteria for the pads are as follows:

- Minimum fill thickness is 1 m;
- Side slopes will be 1.5H:1V (34°) when fill thickness are less than 2 m;
- Side slopes will be 2H:1V (26.5°) when fill thicknesses are great than 2 m;
- No cut is allowed in overburden; and
- The floor of bedrock cuts should slope at 1% to shed water.

4.3.2 Design

The pads are designed with a minimum 1 m fill thickness that consists of a minimum of 0.85 m of geochemically suitable ROQ or ROM material overlain by 0.15 m of surfacing material consisting of crushed rock. The exceptions are waste rock and ore storage pads which do not have the layer of surfacing material. Design analysis to demonstrate the suitability of a 1 m thick rock fill pad for permafrost protection is presented in SRK (2017f).

The process plant pad is to be excavated to bedrock, with the blasted material expected to be suitable for construction of the camp pads. The process plant pad will have a 0.15 m layer of geochemically suitable surfacing material. The terraced camp pads and process plant pad are sloped at 1% towards the contact water pond so that contact water and sediments are collected. A rare plant and archeological site have been identified within the footprint of the process plant pad; these items will be mitigated prior to construction.

While the process plant pad has been identified as a quarry (Quarry AD), the rock produced from this quarry is not expected to be suitable for use in construction. Therefore, this material will be stockpiled in the waste rock pile until it can be placed underground for structural backfill. Detailed design will consider minimizing the cut within this area.

There is no sediment or contact water pond associated with the vent raise pad; therefore, a silt fence may be required the first spring after construction.

4.4 Access and Haul Roads

4.4.1 Design Criteria

Several access roads are needed in the Boston mining area, excluding the Madrid-Boston Road, these include an access road to the contact water pond #1 berm, an access road to the vent raise, an access road to the heliport, the process plant haul road, the water intake and water discharge access roads, and the camp ring road.

The design criteria for the access and haul roads is similar to that used on other roads on-site:

- The design vehicles will be crew cab trucks, personnel transfer busses, Super B fuel trucks and Super B trucks, mine trucks, and lowbed trucks. In addition, construction equipment will periodically travel the road, which is expected to include CAT 988 loaders, and CAT 330 excavators;
- Haul roads shall have a maximum grade of 7%, while access roads shall have a maximum grade of 10%;
- The roadway will be crowned at 0.5% to promote drainage;
- Side slopes shall be 2H:1V (26.5°) when fill thickness is greater than 2 m, and 1.5H:1V (34°) when fill thicknesses are less than 2 m;
- Unless otherwise noted roads shall be single lane with turnouts to allow for passing;
- Single lane access road should be a minimum of 8 m wide and dual lane haul roads should be a minimum of 11 m wide;
- Where road thickness is greater than or equal to 3 m safety berms or barriers will be placed along the road edge, and the road crest will be widened to accommodate the berms; and
- No cut is allowed into overburden.

4.4.2 Design

The process plant haul road will be a 694 m long dual lane, 11 m wide, haul road running from the mill pad to the Madrid-Boston all-weather road. This road can be seen on Drawings BC-02 and BC-04 (Attachment 2). The camp ring road is a single lane, 8 m wide, access road that runs south from where the process plant haul road enters the camp area along the top of the contact water pond #2 berm to the process plant pad (Drawing BC-03, Attachment 2).

The contact water pond #1 berm and access road, is a 8 m wide, 170 m long road that starts from the existing camp pads and ends in a turn out on the east side of the waste rock pile. Two short, single lane, 8 m wide access roads are required to access the heliport and vent raise pads (Drawing BC-02, Attachment 2). The water intake and water discharge access roads will be 8 m wide access roads with 15 m radius turnarounds near the edge of the lake (Drawings BC-15 and BC-16, Attachment 2).

All roads will be constructed of geochemically suitable ROQ or (ROM) material, with a 0.15 m thick surfacing layer.

4.5 Landfill

4.5.1 Design Criteria

The non-hazardous landfill at Boston will be similar to that at Doris. The design criteria for the landfill are listed below:

- The landfill shall be a non-hazardous waste landfill;
- Minimum non-hazardous waste storage volume of 50,000 m³;
- The landfill shall be located:
 - Within a quarry;
 - A minimum of 450 m from Boston Camp (R.R.N.W.T. 1990);
 - Where practical, a minimum of 90 m from the Madrid-Boston all-weather road (R.R.N.W.T. 1990); and
 - A maximum of 10 km from Boston Mine.
- The landfill shall be located in an area with low surface runoff, or water diversion should be used to minimize water run-on;
- Ramp grades shall not exceed 5H:1V (11°);
- Ramps shall have a minimum width of 5 m;
- Minimum slope of 0.5% towards a sump to allow for drainage;
- Minimum 1.0 m thick rockfill cover placed at closure; and
- Closure cover shall be sloped at 1% to shed water.

4.5.2 Design

The non-hazardous waste landfill will be located in Quarry V and accessed by a 1,260 m long road (Drawings BC-10 to BC-12, Attachment 2). The landfill will have a surface area of 11,000 m². The quarry floor will drain to a sump at a slope of 1%.

The capacity of the landfill is to be defined by the waste storage volume required. The maximum capacity is constrained by the size of Quarry V. The minimum design volume is expected to be 50,000 m³. This is the same approach undertaken for the Doris landfill to be located within Quarry 3.

Two sides of the landfill will abut the quarry highwalls, the other two sides of the landfill will consist of berms constructed of geochemically suitable transition (0.15 m minus) material. The berms shall have a minimum crest width of 3.0 m and minimum side slopes of 2H:1V (26.5°).

Geotechnical information on the bedrock quality at the proposed landfill location (Quarry V) is not currently available. The geotechnical quality of the bedrock will be assessed following completion of quarrying operations in Quarry V and prior to IFC design of the landfill.

Waste should be placed and compacted within the landfill in 0.85 m thick lifts. A series of 0.15 m thick interim covers of geochemically suitable surfacing material shall be placed as needed to prevent the production of dust. Alternatively, non-hazardous waste could be placed in seacans which would be placed within the landfill.

At closure, the facility will be covered with an isolation cover which shall have a minimum thickness of 0.3 m of geochemically suitable ROQ or ROM material. The closure cover will be sloped at 1% to allow drainage. The landfill will contain only non-hazardous waste and therefore leachate is not a concern. As the leachate is not a concern, the cover is only an isolation cover and does not require freeze-thaw protection. The cover thickness will be the minimum thickness that can reasonably be constructed with the available run-of-quarry rock and that estimated to be about 0.3 m. This is consistent with the currently approved non-hazardous landfill at the Doris Mine.

4.6 Landfarm

4.6.1 Design Criteria

The landfarm will be similar to the existing landfarm at Doris. It will consist of three cells, one for contaminated snow and water, one for clean water (pending discharge) and one for contaminated soil. The landfarm will not be used for treatment as this is inefficient in the arctic, rather it is an area to store hydrocarbon contaminated soils, water and snow. Soil will be stored temporarily within the facility until it can be disposed of underground in permafrost areas. Snow and water will be placed in the contaminated snow and water pond, and hydrocarbons will be separated from the water using an oil water separator. Decontaminated water will be moved into the clean water pond until testing can confirm it meets discharge criteria.

The design criteria for the landfarm are:

- Minimum clean water and soil pond containment volumes of 360 m³;
- Minimum contaminated snow and water containment volume of 550 m³;
- The floor of each cell will sloped at 1% towards a sump;
- Each cell will be accessed via access ramps sloped at 5H:1V (11°);
- Each cell shall be lined with a geomembrane liner; and
- Landfarm berms will have:
 - A minimum of 3.4 m crest width;
 - Inner slopes of 2H:1V (26.5°), and
 - Outer slopes of 1.5H:1V (34°).

4.6.2 Design

The landfarm berms will be constructed of geochemically suitable transition material, and bedding material. The landfarm cells will be lined with a textured HDPE liner sandwiched between two layers of non-woven geotextile. A 0.15 m thick layer of bedding material will be placed below the liner system and a 0.6 m thick layer of bedding material will be placed above the liner system (Drawing BC-07, Attachment 2). All materials should be placed and compacted in accordance with the Technical Specification (SRK 2011).

4.7 Fuel Storage Facility

4.7.1 Design Criteria

The fuel facility will include six 1.5 million litre fuel storage tanks (five diesel tanks and one aviation fuel tank) and a fuel transfer station for refueling of vehicles. Design criteria for the fuel facility is as follows:

- Fuel storage tanks and transfer station will be within a lined facility to provide secondary containment;
- The design vehicles for the facility are crew cab trucks and Super B train fuel trucks (60,000 L capacity);
- The secondary containment facility will be designed to contain 110% of the fuel tank volume of the single largest tank, and all the rainfall from the 1:100 year, 24-hour storm runoff (55 mm), and the average maximum daily snowmelt (18 mm); and
- The containment area should have a minimum slope of 1% towards a sump.

In addition, the fuel facility should be designed to the following codes and guidelines:

- NFPA 30, Flammable and Combustible Liquids Code, 2015 Edition (NFPA 2014);
- SOR/2008-197, Storage Tank Systems for Petroleum Products and Allied Petroleum Products Regulations (Government of Canada 2012); and,
- Environmental Code of Practice for Aboveground and Underground Storage Tank Systems Containing Petroleum and Allied Petroleum Products (CCME 2015).

4.7.2 Design

The entire footprint of the fuel facility will be lined with an HDPE geomembrane sandwiched between two layers of 12 oz non-woven geotextile. A 0.15 m thick layer of bedding material will underlie the geomembrane, and a 0.3 m thick bedding layer will overlie the geomembrane. The interior of the facility will also have a 0.3 m thick layer of surfacing material.

The fuel tanks will be located in a row in the center of the facility, a minimum of 3.0 m from the base of the containment area berms, and 9.8 m between tanks to allow access. The containment berms will be constructed of transition material overlain by the geomembrane and bedding layers described above. To reduce the amount of construction material required and the height of the containment berms, the base of the fuel facility will be cut into bedrock. The berms will have interior slopes of 2H:1V (26.5°) to allow for geomembrane placement and will have exterior slopes of 1.5H:1V (34°). The secondary containment facility will have a surface area of 8,400 m² and a minimum containment capacity of 2,750 m³.

There will be a 6 m wide ramp allowing vehicles to drive through the fuel facility. Ramps sloping at 5 to 6% enter and exit the facility. A flat area within the facility is where the fuel transfer module will be set up and where refueling will occur.

Details of the fuel facility design are presented in Drawing BC-06 (Attachment 2).

4.8 Explosives facility

4.8.1 Design Criteria

An explosives facility for the Boston mining area will be located in one of the quarries along the Madrid-Boston all-weather road, as determined by negotiation with the regulators. This facility will be sited to meet the setback requirements outlined in regulations and guidelines. A preliminary design as per NRCAN 2007 and NRCAN 1993 has been developed and shows the explosives facility within Quarry V as presented on Drawings BC-13 (Attachment 2). This is the same design as the permitted explosives facility at Doris. The Boston explosives facility will only be developed within Quarry V once quarrying of the final selected Quarry is determined complete. The design is shown on existing surface contours; however the final layout of the Boston explosives facility will be determined based on final quarry surface.

4.9 Reagent Facility

4.9.1 Design Criteria

The reagent facility will be separated into two lined containment areas, one area for acid and one area for bases. Design criteria for the reagent facility are as follows:

- Shipping containers (seacans) filled with reagent will be stored within a lined facility to provide secondary containment;
- The reagent facilities will be designed to contain 100% of the volume of one shipping container (67 m³) and all the rainfall from the 1:100 year, 24-hour storm runoff (55 mm), and the average maximum daily snowmelt (18 mm);
- The design vehicle for the facility is the Hyster HR45-40LS reach stacker;
- The base side of the reagent facility should be large enough to contain 24 shipping containers without stacking, and the acid side should be large enough to contain six shipping containers without stacking;
- Containers should be located a minimum of 2.5 m from the toe of the containment berms to allow for snow clearing;
- Containers can be stacked a maximum of two high; and
- The base of each cell should be graded towards a sump with a minimum slope of 1%.

4.9.2 Design

The reagent facility berms will be constructed of geochemically suitable transition material, and bedding material. The reagent facility cells will be lined with a textured HDPE liner sandwiched between two layers of non-woven geotextile. A 0.15 m thick layer of bedding material will be placed below the liner system and a minimum 0.9 m thick layer of bedding material will be placed above the liner system in the floor of the facility. An additional layer of textured HDPE liner and non-woven geotextile will be placed at the access ramp location to prevent puncture of the liner. All materials should be placed and compacted in accordance with the Technical Specification (SRK 2011).

Details of the reagent facility design are presented in Drawing BC-08 (Attachment 2).

5 Construction Methodology

All construction fill materials will be obtained from geochemically suitable permitted quarries, or geochemically suitable waste rock. Management and monitoring of these quarries will be according to the quarry monitoring plan (TMAC 2017). Surfacing (32 mm minus), bedding (19 mm minus), and transition (150 mm minus) materials will be produced at an on-site crusher located within one of the permitted quarries. The estimated construction quantities are provided in Drawing BC-17 (Attachment 2).

All material excavated from Quarry AD is not expected to be geochemically suitable (SRK 2017g) for construction usage, so all material excavated from this quarry will be stored for use as underground backfill material.

Based on previous surface infrastructure construction on the Project, it is assumed that the construction fleet will consist of CAT 730 haul trucks, CAT 773 haul trucks, CAT D8 dozers, CAT C330 excavator(s), CAT CS563 compactor and a crusher.

Prior to construction the road alignments and pad areas should be cleared of snow and ice. At no time will disturbance of the tundra vegetation or soils be allowed outside of the road footprint, and no permafrost disturbance will be allowed. Construction fill will be placed by end-dumping on the existing road or pad surface and pushing the dumped material with a bulldozer. Surfacing material will not be placed until the ROQ material layer is at design grade and level. All construction should be performed in accordance with the Technical Specifications (SRK 2011). Where necessary, rock drains will be installed at topographic lows to ensure no standing water is created along the edges of roads or pads. Prior to quarry excavation all overburden material should be stripped and placed in the overburden dump.

Wherever possible, pads and roads will be constructed in the winter to ensure the foundation materials remain frozen. Summer construction may be required to meet development schedules. Winter and summer construction techniques will be identical; however, summer construction will result in the use of more construction material as greater imbedding of material into the active layer will occur. Summer construction will also require careful screening of the site for nesting birds, and modifications to the construction schedule may be required to avoid disturbing nesting birds.

Attachment 1
Dump Stability Rating

Structure Name: Boston Waste Rock Pile

Key Factor Affecting Stability	Conditions	Description	Rating Points
Pile height (m)	<50m		0
Pile volume (m³)	Small	< 1 million BCM's	0
Pile slope	Moderate	26 - 35 deg	50
Foundation Slope	Flat	<10%	0
Degree of confinement	Moderately Confined	-Natural benches or terraces on slope -Even slopes, limited natural topographical diversity -Heaped, sidehill or broad valley or cross-valley fills	50
Foundation Type	Weak	- Limited bearing capacity, soft soils - Subject to adverse pore pressure generation upon loading -Adverse groundwater conditions, springs or seeps - Strength sensitive to shear strain, potentially liquifiable	200
Pile Material Quality	Moderate	- Moderately strong, variable durability -10 to 25% fines	100
Method of Construction	Favorable	- Thin lifts (<25m thick), wide platforms -Dumping along contours -Ascending construction -Wrap-arounds or terraces	0
Piezometric and Climatic Conditions	Favorable	- Low piezometric pressures, no seepage in foundation - Development of phreatic surface within dump unlikely -Limited precipitation -Minimal infiltration into dump - No snow or ice layers in dump or foundation	0
Dumping rate	Slow	- <25 BCM's per lineal metre of crest per day - Crest advancement rate < 0.1m per day	0
Seismicity	Low	Seismic Risk Zone 0 and 1	0

Dump Stability Rating (DSR)

Pile Stability Class	Failure Hazard	Recommended Level of Effort for Investigation, Design and Construction	Dump Stability Rating (DSR)
2	Low	- Thorough site investigation - Test pits, sampling may be required - Limited lab index testing - Stability may or may not influence design - Basic stability analysis required - Limited restrictions on construction - Routine visual and instrument monitoring	400
Comments: The foundation type listed is for thawed conditions, under frozen conditions the foundation type would be considered intermediate or competent			

Based on the BC Mine Waste Rock Pile Research Committee; Mined Rock and Overburden Piles Investigation and Design Manual, Interm Guidelines, May 1991.

- LEGEND**
- 31m Stream / Lake Setback
 - 50m Underground Workings Buffer
- NOTES**
- The coordinate system is UTM Zone 13, NAD83.
 - Dimensions in metres unless noted otherwise.
 - Contour labels are oriented facing upslope.

LEGEND

- Surfacing Material
- Run of Quarry Material
- Waste Rock

NOTES

- Maximum overall slope angle for waste rock of 2.5H:1V (21.8°) as measured from the toe of the lowest bench to the set-back of the highest bench, assuming inter-bench angle of repose slopes of 1.3H:1V (37°), bench heights of 5 m and bench widths of 6 m.
- Dimensions in metres unless noted otherwise.

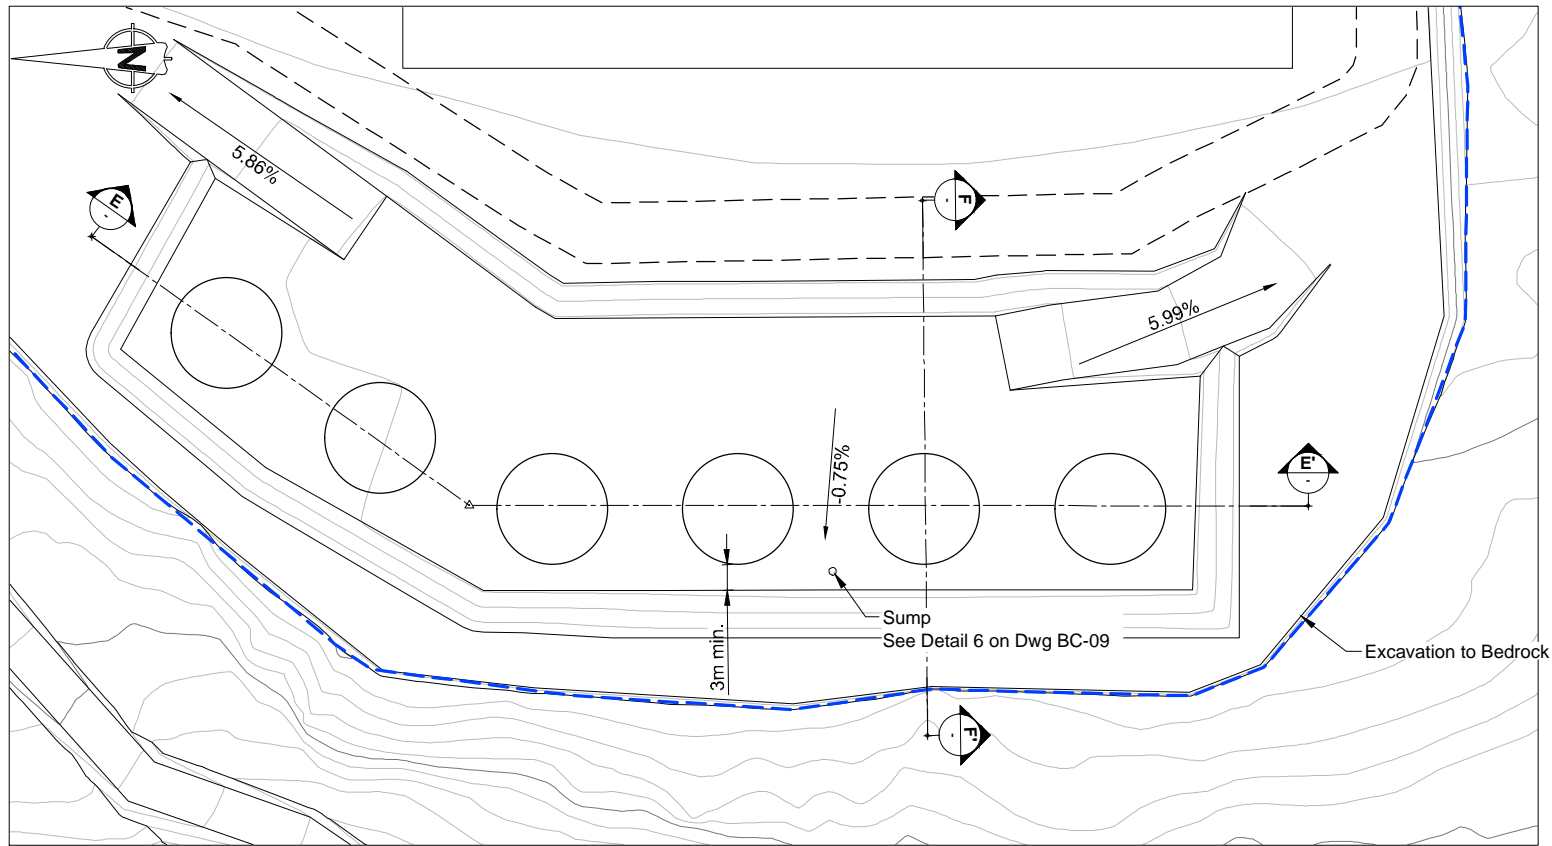

0 5 10 15 20 25
Horizontal Scale in Metres
