

1 that's where the dense media separation plant will
2 be located where the kimberlite will be put into
3 the plant and the diamonds recovered.

4 Located immediately next to the processing
5 plant will be the accommodations where the
6 employees will be staying. And north of the
7 accommodations slightly will be the fuel tank farms
8 location.

9 The small blue sliver that you see at the
10 bottom of the picture is part of the processed
11 kimberlite containment area. That will be the area
12 where the fine processed kimberlite will be sent
13 after it leaves the processing plant.

14 To the right of the picture is a road that
15 goes off through a small lake that we call Lynne
16 Lake, travelling over to Contwoyto Lake, which
17 links us up to the annual winter road that runs
18 north of Yellowknife each year.

19 Tahera Diamond Corporation has been working
20 with the other members of the joint venture winter
21 road committee, and we will be part of that joint
22 venture.

23 CHAIRMAN: Thank you. Just to
24 interrupt here, I wonder if the Board members can
25 see clearly. There is three people there, because
26 the Board members haven't seen this. Thank you so

1 have much. I didn't want to be rude, but the Board
2 members have to see this information. Thank you.

3 GREG MISSAL: Greg Missal, would you
4 like me to back up at all? Okay. I will just
5 maybe touch back on the winter road.

6 The winter road access runs from the Jericho
7 site eastward and slightly south to Contwoyto Lake,
8 which will be our link to the winter road which is
9 built annually up from Yellowknife.

10 The company has utilized this winter road in
11 the past to gain access to this site, so we are
12 very familiar with what it takes to bring the
13 winter road into Jericho.

14 Besides the winter road is the explosives --
15 basically the explosives storage location, and
16 slightly into Carat Lake you can see just a small
17 line there, that's the water intake, or as we will
18 be speaking about, calling it the causeway where
19 the water will be drawn from Carat Lake, up to the
20 process plant and the accommodations facilities, as
21 well.

22 And also just south of the causeway, you will
23 see a slight curved stream, that's what we refer to
24 as the Stream C1 diversion, that's a small stream
25 that currently runs through the outline of where
26 the open pit will be located. We are proposing to

1 divert Stream C1 around what will be the ultimate
2 open pit and join back into its natural flow
3 location into Carat Lake.

4 In terms of our water requirements, for fresh
5 water requirements, the majority of the makeup of
6 that is for the processing plant. We will also
7 have a need for potable water or for use of the
8 camp. And of course there is going to be small
9 miscellaneous uses as well, such as some water to
10 be used for any of that ice road construction going
11 over to Contwoyto Lake, any fire protection, or
12 such things as hydrostatic testing. And, of
13 course, as I mentioned, our main water source for
14 that is Carat Lake.

15 This is a slight schematic of the Jericho
16 kimberlite as it is located in the ground, and you
17 can see the lines that go around it, that basically
18 represents the outline of the open pit that we will
19 be digging or developing in order to mine or
20 extract this kimberlite material. That's the
21 approximate location of that kimberlite, it is --
22 as you can see from here, it is a land-based
23 kimberlite which is slightly unique to most
24 kimberlites. Quite often kimberlites are found
25 under lakes or partially under lakes. In this
26 case, we are very fortunate that the kimberlite is

1 a land-based kimberlite.

2 This is a bit of a difficult slide to read,
3 but the intent of it was to show that the company
4 has been doing many, many years of baseline study
5 collection, and we feel we have covered all the
6 points that are required to give us a very good
7 knowledge of the circumstances that exist at
8 Jericho in terms of requiring this baseline data.

9 You can see it began as far as back as 1995
10 and has carried up into 2004 with some
11 predevelopment monitoring work and some
12 geotechnical work this past summer.

13 I have introduced the team a little earlier.
14 As I mentioned very briefly, this team has been
15 together for quite some time working on this
16 project. And for some of them it has been many
17 years, in fact, and I believe that this group of
18 people are experts related to this project. They
19 have spent the most time and have the most
20 knowledge of the circumstances that affect this
21 project and would have gone into the work that we
22 have prepared to show you today and the work that
23 went into our submission to you.

24 So with that, I will start with Cam Scott to
25 my right who is going to speak to you about the
26 geotechnical work that he has been working on.

1 CAM SCOTT: Mr. Chair, this
2 presentation that I'm going to give right now
3 basically talks about the mine waste management for
4 the project. It is a lot of the other discussions
5 will follow related to water, will follow logically
6 from this presentation which will set up the mine
7 waste management side of things.

8 The first slide basically just gives an
9 overview of the content of what I will go through,
10 starting off with just an overview of the mine
11 waste materials, followed up with a discussion of
12 the waste rock piles and kimberlite stockpiles,
13 specifically the layout, some of the improvements
14 that we have made since the submission of the FEIS
15 some years ago. Foundation conditions, design and
16 some of the very brief comments on the dam
17 construction.

18 The next portion will just touch on the
19 processed kimberlite containment area, and again
20 layout and filling, foundation conditions, design
21 and very brief comments on construction.

22 The second-last component will deal with
23 monitoring as it relates to these elements, and we
24 will finish up with just some comments on the
25 closure plan.

26 This first slide illustrates the main

1 components or the main materials associated with
2 the mine waste from the project. The first part,
3 the overburden soils, the soils overlying the ore
4 body comprise mainly of boulders, sands and gravels
5 with some silt. And there is the tonnage that goes
6 with it. The second component, the waste rock,
7 which is primarily granitic waste rock associated
8 with the extraction of the kimberlite.

9 The next component, low-grade ore, which is
10 basically kimberlite, it is low grade insofar as
11 what we know presently. It may well get -- the
12 plan of Tahera is to, in fact, process that
13 material based on the assessment of some of the
14 initial production and running that through the
15 plant.

16 The actual production component is the coarse
17 PK and the fine PK, which is processed kimberlite.
18 Two fractions, the coarse fraction is basically
19 like a gravel and comes out of the plant in that
20 form and is handled by mechanical equipment. The
21 fine PK is a very, very fine silty slimy material,
22 and it is produced as a pipeline product from the
23 plant and is piped to its containment area.

24 Just to give people an appreciation of the
25 scale of the project, you can see the Jericho
26 numbers, and we have added the Ekati production

1 from one year, 2002. So if we look at our waste,
2 our overburden and waste rock, we have got
3 basically 15 million tonnes based over life of mine
4 for Jericho, and for one year at Ekati, it is round
5 numbers, approximately 45 million tonnes. So
6 essentially we have got a three-time factor based
7 on one year production at Ekati compared to the
8 life of mine for the Jericho project.

9 If you look at the low-grade ore and the
10 coarse PK and the fine PK, it is sitting at around
11 4 million, and it is a similar number of actual
12 production of the processed kimberlite at Ekati.
13 So you can see the magnitude of the scales of the
14 project.

15 This slide illustrates the production in
16 years, starting with year one, extending through to
17 year nine of these various waste materials. The
18 overburdened soils coming out basically in years
19 one and two, very early in the start of the
20 project. Mine waste or waste rock produced through
21 the first four years through the open pit, there
22 will be some incremental production of waste rock
23 as part of the underground operation, but it is
24 very small by comparison to the production that you
25 see here.

26 Low-grade ore, first four years, and of

1 course the processed kimberlite associated with the
2 project, starting perhaps just slightly in the
3 first year, extending primarily for the next eight
4 years and going through the life of the project.

5 This slide basically just gives a little more
6 detail to what Greg touched on earlier. We have
7 the waste rock pile 1, overburden waste rock pile
8 2, which is primarily where the overburden goes.
9 Down here, of course, processed kimberlite, and
10 here the low-grade ore stockpile.

11 Just so people appreciate some of the
12 modifications or improvements that have been made
13 based on input from reviewers over the course of
14 the NIRB process and other inputs along the way,
15 the first thing I would point out is the green line
16 that runs along here, and that green line basically
17 separates the two watersheds, water which flows to
18 the north towards Carat, and water which flows
19 south towards Key Lake and on into Contwoyto.
20 Basically what we have done is we have moved all of
21 those waste elements onto the watershed leading
22 into Carat and kept out of this watershed to the
23 south.

24 In addition, some of you may recall there was
25 an overburden pile here as well as a waste-rock
26 pile here. We have moved the overburden pile that

1 was at this location to here, switched it with the
2 waste rock so it is back here and then merged those
3 two piles and moved it slightly up the hill. The
4 advantage to that is now we have the capacity to
5 move drainage from this pile more easily into the
6 open pit during operations and at closure.

7 Moving on to the foundation conditions
8 associated with these structures, basically they
9 consist of bedrock, or in some cases bedrock with a
10 thin soil cover, but predominantly bedrock is the
11 foundation.

12 All of these sites are underlain by cold
13 permafrost. And when I say cold permafrost,
14 temperatures significantly colder by way of example
15 than you would have in Yellowknife, where you would
16 have what I call warm permafrost.

17 This section illustrates fairly typically
18 what the slopes will be on each of the various
19 facilities. The black line that you see there is
20 representing the benches at which the material will
21 be placed as part of the final slopes for each of
22 the facilities. The steep segment on each of
23 those, the materials placed at the angle of repose.
24 The fine black line that goes from crest to toe
25 illustrates the overall slope, which is
26 approximately 21 degrees. And the red line that

1 you see there, at closure we will just take the
2 caps off, the sharp edges off, and grade that down
3 to approximately an average slope of 19 degrees.

4 Insofar as the design and construction, for
5 most of these facilities, most of these piles and
6 stockpiles, we will attempt to put the first lift
7 of material in winter to try and preserve the
8 permafrost in the ground.

9 Where the stockpile comprises kimberlite,
10 such as the low-grade ore and the coarse processed
11 kimberlite pile, where there is organic soil, prior
12 to placement of the kimberlite, there will be a
13 thin deposit or layer of granitic waste rock placed
14 over that, and that is basically for geochemical
15 reasons to provide separation between the
16 kimberlite and the organic soils. Kelly Sexsmith,
17 I think, will be touching a little bit on that
18 later.

19 These lift thicknesses, each of those is
20 approximately 10 metres, and as I mentioned, the
21 overall slope is about 21 degrees.

22 Moving on to the processed kimberlite
23 containment area, this is a shot of the facility
24 near the end of the mine life. I would draw your
25 attention to this structure here, this is the west
26 dam, this is what we referred to it. There is a

1 structure at this location called the north dam, it
2 is a contingency item at the moment.

3 The divider dike which separates the pond,
4 the PKCA pond from the fine processed kimberlite,
5 and then we have a dam at the east side and a dam
6 at the southeast side.

7 Actually, could we just go back one? Just to
8 carry on with the concept of just touching on the
9 improvements that has been made, as a result of
10 input from intervenors and others over the past few
11 years, I want to point out that the divider dike is
12 in fact back in, and that is different from where
13 we were during the NIRB hearings, and it reflects
14 primarily the difference in the deposition process.
15 The fine processed kimberlite will be discharged by
16 a pipeline from this end, and the intention is to
17 put this divider dike and provide separation
18 between the processed kimberlite and the pond.

19 So this pond here acts as a settling pond,
20 and as a consequence of that, some of you may
21 recall that there was a sediment settling pond at
22 this location west of the west dam, and that is
23 essentially a contingency element now and not part
24 of this current base plan.

25 Just very quickly an overview on the
26 processed kimberlite containment area. All of the

1 dams have been designed in accordance with the
2 Canadian Dam Association's guidelines. To give
3 you the sense of scale, the dams are approximately
4 9 to 12 metres high. And as mentioned earlier, we
5 have storage of the processed kimberlite to the
6 east side of the divider dike. There is sufficient
7 capacity to store the tailings in that area or to
8 store the processed kimberlite in that area, even
9 with a significant degree of ice entrainment which
10 will likely occur as a result of the climate and
11 operations during winter.

12 This facility also has a capacity for
13 suitable water management and flood capacity
14 handling. And the earthquake design criteria on
15 which the dams are based is the 1 in 2475-year
16 earthquake. Essentially for the 2005 year, that's
17 the design earthquake that the National Building
18 Code of Canada is recommending.

19 So this slide just shows how the development
20 of the kimberlite -- the filling of the facility
21 with occur. Starting in the year 2006, again
22 discharging from these dams at the east end of the
23 facility. Into 2007, the deposit is getting
24 larger. Through to 2008, and we are starting to
25 get pushed down towards the divider dike. And by
26 the end of -- as time goes on, the elevation of the

1 processed kimberlite rises, but the footprint stays
2 more or less the same, some advancement over to the
3 south.

4 The foundation conditions at the processed
5 kimberlite containment area consist on the
6 abutments or the sides of the valley of bedrock, or
7 in some cases with a soil deposit overlying
8 bedrock. In the valley floor, under the lake and
9 along the alignment of the lake, there are glacial
10 deposits, boulders, cobbles in a glacial till
11 matrix of silt, sand and gravel. And all of the
12 dam sites are underlain by several hundred metres
13 of cold permafrost.

14 By way of example, there is something in the
15 order of 540 metres of permafrost at Lupin, and
16 approximately 400 metres at Ekati, and we would be
17 in the same sort of situation here at Jericho.

18 This is the west dam showing a spillway on
19 the one abutment. This structure is the most
20 important in terms of containment of water from the
21 entire operation. I will just point your attention
22 here to this section line on this next slide.
23 There is a cross section through that dam. We
24 point out, this is where the water would be
25 accumulating on this side.

26 The water at this level we anticipate to be

1 the normal operating level, so fairly low in terms
2 of elevation, 515, 517. The spillway would be
3 situated up at a 523, which is what you see here.
4 And it may rise slightly to the extent that water
5 were to flow through that, but we envisioned that
6 would be a very extreme and likely case. The base
7 case, as I mentioned, has our water level down at a
8 fairly low operation level.

9 The structure itself, this is the dam in this
10 area, consists of a frozen core, which is soil
11 which has been placed in the middle of winter under
12 very cold temperatures and compacted with an
13 appropriate care and attention and quality control.

14 Thermosiphons, which are tubes linked to the
15 surface that provide effectively refrigeration and
16 it provides a cooling in this area, and provides a
17 good bond between the frozen core and the
18 underlying permafrost.

19 The brown line that you see there is
20 especially what is called a geocomposite clay
21 liner. It is essentially almost two pieces of
22 carpet with clay in between, and it is a secondary
23 containment element to the whole design of this
24 feature.

25 One thing I just want to point out, the
26 elevation, this is our seepage containment, the

1 elevation to the top of it is 524, so it is, in
2 fact, one metre above the level of the inlet to the
3 spillway.

4 The rest of the structure is composed of
5 waste rock from the operation, either crushed or
6 run-of-mine waste rock.

7 Now you recall the divider dike that we
8 talked about which defines and separates the pond
9 and the processed kimberlite. So here we have the
10 processed kimberlite in this area, and then the
11 pond over on this side.

12 This structure is important for a variety of
13 reasons. Its primary objective during operations
14 is to prevent the movement of fine processed
15 kimberlite through this structure and into this
16 pond. On the other hand, it is important that it
17 pass water, so essentially it is quite coarse.

18 And what we have up here is a series of
19 filters or transmission materials, effectively a
20 filter to prevent the movement of fines. So it
21 will be built in stages starting as early as this
22 summer at elevation 517. And then as time goes on,
23 we will place, you know, before the processed
24 kimberlite gets to this location, the installation
25 of this filter zone. And as time goes on, as the
26 processed kimberlite rises, the structure gets

1 raised higher as well.

2 We will talk a little bit about closure
3 later, but this structure ultimately becomes a
4 containment element at closure for all the
5 processed kimberlite upstream of it.

6 This is the typical section through the dams.
7 The fundamental difference between these
8 structures, the dams at the east side of the
9 facility are that there is a beach or a zone of
10 processed kimberlite against the structure, so
11 that's distinctly different than what the situation
12 we have at the west dam where we have water ponded
13 against it. As a consequence, what we have here is
14 a frozen core dam which provides containment in the
15 first year of operation for water to the extent
16 that we had elevated water levels.

17 In general, the pond will be situated well to
18 the west of this structure. And so we don't need
19 the same level of engineering containment or
20 seepage control at this structure that we have at
21 the west dam.

22 So as I mentioned, you have got a frozen core
23 here, and, again, a waste rock structure through
24 the rest of the dam. And to the extent that we
25 need incremental storage, we simply have to raise
26 the structure to get in and allow the tailings to

1 discharge from the crest of the dam until the
2 processed kimberlite builds up against it.

3 The construction of these dams is quite
4 conventional in the north, they are frozen-core
5 dams. The technologies and procedures are quite
6 well established. In this case, it will be done by
7 an experienced contractor using winter
8 construction. And as I mentioned, the waste rock
9 and esker sands and materials available onsite, and
10 Don Hayley will be talking a little bit following
11 my presentation, will cover off more details on
12 just the general experience in the north with these
13 types of structures.

14 Okay, moving on to the monitoring systems. I
15 draw your attention. This is obviously a site
16 plan, I draw your attention to this part of the
17 drawing, purple, pit monitoring, green,
18 thermistors, which effectively measure temperature
19 and survey hubs for measuring displacements.

20 This is the open pit, and I'm just showing
21 one indication of monitoring at the open pit.
22 Primarily geared to pit slope monitoring and
23 performance during the course of operations.

24 The thermistors, again, these green dots,
25 there is a number of them sitting on the waste rock
26 piles. In addition, and over here the coarse

1 processed kimberlite, as well as on the various
2 dams. Survey hubs link primarily to the
3 performance of the dams. Okay, so that's the
4 general overview of the geotechnical monitoring.

5 Specific to the dams, we have the three,
6 west, east and southeast, a series of survey hubs
7 on each of them, as well as thermistors. And I
8 just draw your attention that the west dam, again
9 the most critical in terms of water containment,
10 the thermistors are both two sets of vertical and
11 horizontal strings, and at the east and southeast,
12 just a series of vertical strings of thermistors, I
13 will show you what those all look like now.

14 So this is a typical dam, there is the survey
15 hubs there, one on the upstream crest and one on
16 the downstream crest. This green line indicates
17 the vertical thermistor, so we can measure within
18 the frozen core. And over here, the horizontal
19 thermistor string which goes down through, along
20 the base of the frozen core, and then down into the
21 foundation soil materials so we can confirm the
22 temperature there.

23 Last part of the presentation, the closure
24 concepts, and I just want to mention that the
25 development of the closure concepts is still
26 unfolding, and a lot of the details will depend on

1 things like vegetation trials during the course of
2 the early operation. But as they stand presently,
3 this list of bullets refers to what would be the
4 case.

5 The slide slopes as we mentioned earlier,
6 regraded to about three to one. At the coarse PK
7 stockpile, the concept would be to prevent erosion,
8 so the placement of waste rock and overburden for
9 that objective.

10 Drainage from these piles will be directed to
11 the open pit. Scarification, which basically means
12 during the course of operations, the surfaces will
13 become flat and fairly smooth and fairly
14 impenetrable to water and not well suited to the
15 potential development of vegetation, so ripping
16 those up, creating a very rough irregular surface.

17 Pending the revegetation trials to determine
18 the feasibilities and concepts for revegetation
19 which will govern where one goes on terms of some
20 of the closure aspects for revegetation, and then
21 lastly, the placement of boulders on dump surfaces
22 as has been pointed out from other individuals that
23 that's a positive thing for certain birds, as well
24 as the establishment of ramps on the piles and
25 stockpiles to facilitate access by caribou.

26 And, lastly, the closure concepts for the

1 processed kimberlite containment area, as mentioned
2 there would be a slope on the processed kimberlite
3 heading down to the divider dike. So at closure,
4 the concept would be to dewater the pond by pumping
5 or siphoning the water out of the pond, and then to
6 breach the west dam, or depending on the situation,
7 lowering the spillway, but the main concept, breach
8 the west dam. In other words, take the dam, a
9 segment of the dam out, so it no longer contains
10 water. Cover the fine PK with the layer of .3 to
11 .5 metre thick of coarse processed kimberlite, and
12 then, again, getting back to the issues of
13 revegetation, probably covering the coarse
14 processed kimberlite by a cover of overburden or
15 waste rock. All of that -- a lot of those details
16 will depend on revegetation trials.

17 So that's the presentation on the mine waste.

18 GREG MISSAL: Thanks very much, Cam.
19 I would just ask Don Hayley to come up now and give
20 his portion of the presentation.

21 CHAIRMAN: Mr. Missal, before we
22 proceed, could we take a 15-minute break, please.

23 Elders, I encourage you to speak up when you
24 have any questions.

25 We will be back in 15.

26 (BRIEF ADJOURNMENT)

1 CHAIRMAN: Welcome back.

2 Mr. Missal, before you proceed, there is an
3 Elder that wanted to make a comment or a question.

4 TOMMY KUGLUKTU (PHONETIC): My name is Tommy
5 Kugluktu. I want to thank the speaking in
6 Inuktitut, so the Elders can understand me. What I
7 am hearing from, I seem to favour what I am hearing
8 so far, and if it should be approved would be good.
9 Coppermine has many, many people now, majority
10 children, and we have many young people, they need
11 to continue school, there has to be incentives so
12 that they can find work, get the training. Our
13 youth, I want to -- in support of our youth, that
14 they have a future. I want to -- initially I think
15 it sounds good, and if I should be here again
16 tomorrow and take in more of the proceedings I will
17 probably speak more again.

18 But it is understanding what we are hearing,
19 and it is quite clear as we are -- as our youth
20 come to understand these developments more and
21 more, and they learn more and learn more about
22 vehicles, operation of heavy equipment and any
23 other trades and employment opportunities that may
24 be available in the future.

25 The land of the Inuit, we appreciate and we
26 take the resources, but it is to the benefit of our

1 youth. Thank you.

2 CHAIRMAN: Please state your name
3 when you speak. Thank you.

4 Okay. Mr. Missal, please proceed.

5 GREG MISSAL: Thank you very much,
6 Mr. Chair.

7 I would like to ask Mr. Don Hayley to give
8 his portion of the Tahera presentation.

9 DON HAYLEY: Mr. Chairman, Board
10 members, ladies and gentlemen. My name is Don
11 Hayley. I'm with EBA Engineering Consultants. We
12 specialize in northern engineering from our offices
13 in Yellowknife.

14 I have been working together with Mr. Scott,
15 whom you just heard, on the design of the water
16 retaining and processed kimberlite retaining
17 structures that are required for the project at the
18 processed kimberlite containment area.

19 What I would like to do tonight is give you a
20 little bit of background on some of the precedents
21 that have been over the last ten years with design
22 and structure of what we call frozen-core dams in
23 this part of the Canadian Arctic.

24 The designs that Mr. Scott presented earlier
25 are based very much on experience that we have
26 gained over the past eight years at the Ekati
