SECTION 1 • INTRODUCTION

Meadowbank Mining Corporation (MMC), formerly Cumberland Resources Ltd. (Cumberland), is proposing to develop the Meadowbank Gold Project located approximately 70 km north of Baker Lake in Nunavut. The Project is subject to the environmental review and related licensing and permitting processes established by Part 5 of the Nunavut Land Claims Agreement (INAC and TFN, 1993).

On March 31, 2003, Cumberland submitted its Project Description Report for the Meadowbank Gold Project to the Nunavut Impact Review Board (NIRB). Following receipt of the MMC's application and NIRB's screening review the Minister of the Department of Indian Affairs referred the Project to an environmental impact review under Part 5 or 6 of Article 12 of the Nunavut Land Claims Agreement.

Following submission of a Final Environmental Impact Statement (FEIS), and completion of the screening and environmental impact review process, NIRB recommended that the Project proposal proceed subject to certain terms and conditions. On November 17, 2006, the Minister of Indian and Northern Affairs Canada, on behalf of the federal government and pursuant to Article 12.5.7 of the NLCA, approved the Nunavut Impact Review Board's recommendation and the Meadowbank Gold Mine Project Certificate (Nunavut Land Claims Agreement Article 12.5.12) was issued (NIRB, 2006).

The following document provides a plan for the sampling and testing of the waste materials to be generated as part of the mining process at the Meadowbank Gold Project. The purpose of this testing will be to characterize the acid rock drainage (ARD) and metal leaching (ML) potential of these materials. This characterisation will be used to develop an adaptive waste disposal plan such that waste with a significant ARD/ML potential will be disposed of in a manner that minimizes the likelihood for generating poor quality drainage. This information was identified by NIRB as requirement # 15 for Meadowbank's water license application (NIRB, 2006), as follows:

Cumberland shall within two (2) years of commencing operations re-evaluate the characterization of mine waste materials, including the Vault area, for acid generating potential, metal leaching and non metal constituents to confirm FEIS predictions, and re-evaluate rock disposal practices by conducting systematic sampling of the waste rock and tailing in order to incorporate preventive and control measures into the Waste Management Plan to enhance tailing management during operations and closure. The results of the re-evaluations shall be provided to the NWB and NIRB's Monitoring Officer.

This document provides a plan for systematic sampling of waste and recommends disposal practices that incorporate preventive measures to minimize generation of ARD and ML from the rock storage facilities (RSF).

SECTION 2 • BACKGROUND

The Meadowbank Gold Project consists of several gold-bearing deposits. The three main deposits are Vault, Portage (including Third Portage, North Portage, Bay Zone and Connector Zone), and Goose Island (see Figure 2-1). The Third Portage deposit, Bay Zone, Connector Zone, and North Portage deposit will be mined from a single pit termed the Portage Pit. The Goose Island deposit lies approximately 1 km to the south of the Third Portage deposit, beneath Third Portage Lake, and will be mined from a single pit termed the Goose Island Pit. The Vault deposit is located adjacent to Vault Lake, approximately 6 km north of the Portage deposits, and will be mined from a single pit termed the Vault Pit. Mining will be a truck and shovel open pit operation. A series of dikes will be required to isolate the mining activities from the lakes.

There are four major bedrock types found at Meadowbank: intermediate volcanic (IV), iron formation (IF), ultramafic (UM), and quartzite (QZ). Each of these rock types is present in both the Portage and Goose Island Pits. The Vault Pit, however, consists almost exclusively of IV. Table 2-1 summarizes the estimated quantity and proportion of each of these rock types that will be mined as waste during operation.

Table 2-1: Estimated Quantity and Proportion of Waste Rock Types

Rock Type	Estimated Qu	Lithological Distribution of Pit Rock (%)		
	Goose/ Portage	Vault	Total	
IV	26	68	94	54
IF	34	0	34	20
UM	42	0	42	24
QZ	3	2		
Total	105	68	173	100

^{*} Source: Schedule provided by AMEC (2005).

It is proposed that construction of the mine site infrastructure, including dikes, roads, foundations, and capping for reclamation purposes, will use waste rock and till produced during mining. The composition of the till at Meadowbank ranges from silty sand to pebbles to boulders. Unused (i.e. surplus) quantities of waste rock and till from Portage and Goose Island will be placed in the Portage RSF, except for the Portage waste rock produced during years 3 through 5 of operation, which will be backfilled into the Portage Pit. Surplus material from Vault will be placed in the Vault RSF. Table 2-2 presents a summary of the estimated tonnage of each waste type to be used in construction or placed in a pit or RSF during mine life.

.

¹ It should be noted that the terms "till" and "overburden" have previously been used synonymously, however, the term "overburden" is currently considered to include both till and lake sediments.

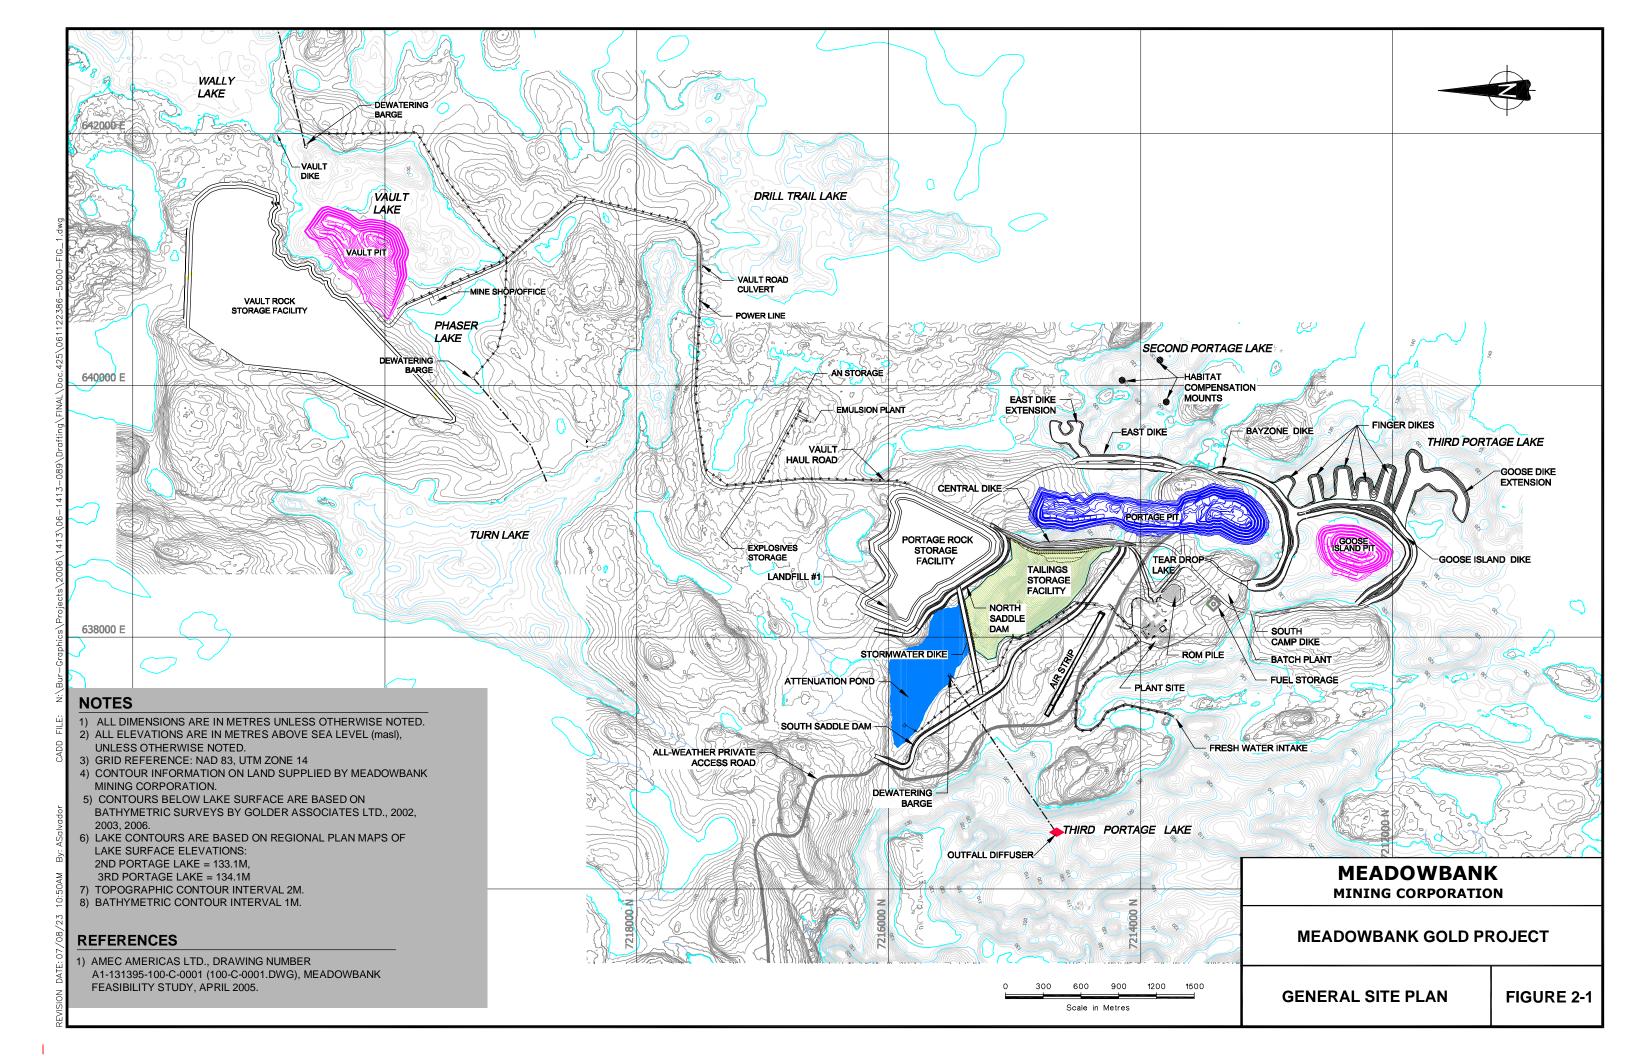

Table 2-2: Summary of Estimated Waste Destinations and Tonnages

Waste Destination		Total				
Destination	Till	IV	IF	UM	QZ	
Dikes	1.8	5.7	8.1	3.7	0.2	19.6

Vault RSF	-	68.2	-	-	-	68.2

^{- 1.} It is assumed that the block model will be used to predict the rock type of material to be blasted.

2.1 ARD/ML POTENTIALS AND CONTROL MEASURES

The ARD and ML potential of Meadowbank wastes have been evaluated through both static and kinetic testing. Details on the test methods used and results obtained are provided in (Golder, 2005a and 2005b), and summarized in Appendix A. Mine waste management options were developed for each rock type based on the results of this testing, as summarized in Table 2-3.

^{- 2.} Includes site roads, mill foundations, and the airstrip.

Open Pit	Waste Type	ARD Potential	ML Potential	Restrictions for Storage or Use in Construction
	Till	None	Low	None ¹
All Pits	Tailings	High	High	Requires measures to control ARD
	Lake Sediment	Variable (none to high)	High	May require collection and treatment of drainage
	ИМ	None	Low	Drainage quality to be monitored
Portago	IV	Variable (none to moderate)	Moderate	Requires measures to control ARD
Portage & Goose	IF	High	High under ARD conditions - Low under buffered conditions	Requires measures to control ARD
	QZ	High	Low	Co-disposal with ultramafic/mafic volcanic or cap/water cover
Vault	IV	Low	Variable (low to moderate)	May require collection and treatment of drainage

^{- *} Source: Cumberland, 2005.

As shown in this table, the waste types that will report to the RSFs show variable ARD potentials, some of which will require control measures. To address this, it is proposed that each RSF is constructed as a cell, or series of cells, such that the interior of each cell is composed of any potentially acid generating (PAG) and/or metal leaching (ML) waste, and the exterior of each cell is composed of non-PAG (NPAG) waste, as shown conceptually on Figure 2-2. The limits of each cell will be defined by a low berm, prior to, or concurrent with, placing material within the cell. Thus, any PAG and/or ML waste within each RSF will be encapsulated within NPAG waste, thereby limiting its exposure to oxidizing agents such as air and water, and providing a buffer for any drainage from the interiors of the cells. Based on the results of thermal modelling, it is expected that the material within the RSFs will freeze within two years of placement (BGC, 2004).

As a further ARD control measure, the Portage RSF will be capped with acid-buffering UM rock at closure. Likewise, the tailings storage facility (TSF) will also be capped with UM rock. The Vault RSF is not expected to require capping, as the bulk of the material from this deposit is NPAG (only 11% of the Vault samples tested were found to be PAG; Golder, 2005a). The UM rock to be used for capping the Portage RSF and TSF will likely need to be stockpiled, as it is not expected that this rock type will be mined in any significant quantity at the end of mine life.

^{- 1.} Metal leaching potential of this waste type is expected to be short-term.

2.2 WATER QUALITY PREDICTIONS

The results of the static and kinetic tests conducted on Meadowbank waste materials were also used to predict the water quality from major mine site components. These predictions were developed using the GoldSim simulation package, with modules designed specifically for Meadowbank. Details on the model assumptions and methods are provided in (Golder, 2005c).

The water quality predictions indicate that arsenic, copper, nickel, zinc, nitrate and ammonia may be found in the Portage RSF drainage. This drainage will ultimately end up in an attenuation/reclaim pond, and would be treated if required. Arsenic may also be found in the Vault RSF drainage, although water from this area is not expected to require treatment.

SECTION 3 • SAMPLING AND TESTING PLAN

Sampling and testing of waste materials produced at Meadowbank will be required during operation in order to segregate the PAG and/or ML waste from the NPAG waste, such that waste materials can be assigned to specific locations. Sampled materials should be inclusive of stripped overburden, drill core or pit walls, and blasthole cuttings. It is not proposed that stripped lake sediments will be sampled, as the total excavated volume of these materials is expected to be relatively low (*i.e.*, less than approximately 1,180,000 cubic metres; Golder, 2006a). Nonetheless, as some lake sediment samples have a demonstrated potential to generate ARD, they will be managed in the same fashion as PAG waste material.

In consideration of the mining rate, test procedures should be rapid and easy to complete. The proposed tests are described in the following subsections and summarized in Figures 3-1 to 3-3. It is anticipated that these tests will be conducted at the assay lab to be constructed on site, which is expected to be running prior to production (MMC, 2007a). Any wastes that are produced prior to the completion of the assay lab will require testing at an external laboratory.

3.1 TOTAL SULPHUR, TOTAL CARBON, AND NET ACID GENERATION (NAG) TESTS AS INDICATORS OF ARD POTENTIAL

3.1.1 Total Sulphur and Total Carbon

The ARD potentials of previously collected samples from Meadowbank were evaluated based on acid-base accounting (ABA), which is a suite of tests that includes paste pH, total sulphur, sulphate sulphur, neutralization potential, and carbonate neutralization potential based on total inorganic carbon. As the name suggests, ABA accounts for both acid generation potential (assumed to be due to sulphide sulphur content, or total sulphur minus sulphate sulphur) as well as acid-buffering potential (referred to as neutralization potential). However, ABA is relatively slow to complete (the average turn-around time at a commercial laboratory is approximately 2 weeks), and requires several different types of equipment and analyses. It is therefore proposed that the ARD potentials of all samples of waste material collected during operation be estimated based on total sulphur and total

NPAG - Not Potentially Acid Generating

RSF - Rock Storage Facility

As - Arsenic

VAULT WASTE ROCK TESTING LOGIC DIAGRAM

FIGURE 3-3

carbon² (to provide an estimate of carbonate neutralization potential), with periodic duplicate checks based on ABA conducted at an external laboratory. It is recommended that these tests be conducted using a LECO furnace (LECO Corporation, St. Joseph, MI, USA) which can analyze both sulphur and carbon content.

3.1.2 NAG Tests

Another type of test commonly used at mine sites, particularly in the Pacific Basin, to characterize ARD potential is the net acid generation (NAG) test (Miller et al, 1997). This test involves crushing and pulverizing a given sample to <75 microns to enhance the availability of minerals, and adding a known volume of hydrogen peroxide (pH 4-7) which rapidly oxidizes any sulphide minerals it contains. This reaction is allowed to progress until all of the sulphide minerals within the sample are exhausted, which typically takes a minimum of 2 hours and may require heating. After the reaction has completed, the pH (NAG pH) of the sample is measured. The solution can then be titrated to a specified pH endpoint using sodium hydroxide, to assess acid forming potential in units of kg CaCO3/tonne equivalent (same units as neutralization potential (NP) and acid potential (AP) obtained from ABA). The results of these tests are achievable in a relatively short period of time, which makes them useful for evaluating the ARD potential of materials on site. It is therefore proposed that the NAG tests be conducted on all samples of waste submitted to the assay lab, and compared to the results of both the total sulphur and total carbon tests conducted on site, as well as the results of ABA conducted at an external laboratory, to determine whether the NAG test may be a more useful or accurate indicator of ARD potential.

3.1.3 Decision Criteria

The most conventional method of evaluating the ARD potential of a material using ABA data is to classify it as PAG, NPAG, or of uncertain ARD potential based on its neutralization potential ratio (NPR). The NPR of a material is calculated as the ratio of its NP to its AP. The ARD potentials of materials collected from Meadowbank were classified using the NPR-based guidelines published by Indian and Northern Affairs Canada (INAC, 1992), which are summarized in Table 3-2.

Table 3-1: Summary	y of ARD Guidelines Used to Classify Mead	lowbank Waste (INAC, 1992)

Initial Screening Criteria	ARD Potential				
NPR < 1	Likely Acid Generating (PAG)				
1 < NPR < 2	Uncertain				
2 < NPR	Acid Consuming				
ZNEK	Not Potentially Acid Generating (NPAG)				

Knowledge of rock chemistry, mineralogy and reactivity of neutralizing minerals support the use of an NPR of 2 to designate rock that is NPAG (Golder, 2006b). Figure 3-4 presents a graph of carbonate

_

² It is not expected that the wastes produced at Meadowbank will contain organic carbon in any appreciable amount.

NP versus bulk NP data obtained to date for waste rock samples from Meadowbank. As shown on this graph, carbonate NP and bulk NP correlate relatively well for these samples, which suggests that NPR values calculated using carbonate NP would be comparable to NPR values calculated using bulk NP. It is therefore initially proposed that the waste samples submitted to the assay lab be classified according to the previously used guidelines (i.e. Table 3-2), using NPR values calculated from the total sulphur and total carbon contents provided by the assay lab. Any samples that are classified as having an "uncertain" ARD potential using these guidelines will be considered PAG for the purpose of material placement. These criteria will be re-evaluated on a bi-annual basis, as additional ABA, total sulphur, total carbon, and NAG test data become available. Should the NAG test be found to be a more useful or accurate indicator of ARD potential in the future, it may be used to classify waste materials according to ARD potential on site instead.

3.2 TOTAL METALS AS INDICATORS OF METAL LEACHING POTENTIAL

The ML potentials of previously collected waste rock samples were evaluated based on shake flask extraction (SFE) tests and humidity cell tests. Both of these types of tests involve leaching samples with water, followed by measuring the metal content of the water after a prescribed period of contact time (24 hours for SFE tests and weekly 24 hour trickle leaches over a minimum of 20 weeks for humidity cell tests), and are thus time-consuming by design. Consequently, it will not be feasible to segregate waste materials based on ML potentials derived from either of these types of leaching tests. It is therefore proposed that total concentrations of individual metals found in rock leachate be tested at the assay lab on site, and that periodic SFE tests be conducted on duplicate samples at an external laboratory, in order to assess whether correlations between total and leachable metals can be made³. If such correlations can be established, criteria that classify the ML potential of materials based on total concentrations of individual metals found in rock leachate will also be established. It is also proposed that the drainage from the RSFs and UM stockpile be monitored for metals found in rock leachate.

_

³ It has not been possible to make such correlations based on the data obtained to date.

MEADOWBANK GOLD PROJECT TYPE A WATER LICENSE APPLICATION

Based on the results of the static and kinetic testing and water quality modelling performed to date, it is proposed that IF and Portage/Goose IV samples that have been classified as NPAG be tested for total arsenic, copper, nickel and zinc, and that UM and Vault IV samples that have been classified as NPAG only be tested for total arsenic. Total metal tests have not been proposed for samples that have been classified as PAG, as the material represented by such samples will be encapsulated regardless of any ML potential. The total metal tests to be conducted in the site assay lab could be performed using x-ray diffraction (XRF), or multi-acid digestion followed by ICP scans. The mineralogy of all NPAG rock samples will also be described, recorded, and compared with the results of the total metal and SFE tests.

3.3 QA/QC

The assay lab on site will be certified for all analyses, and standard analytical QA/QC procedures will be followed to ensure quality of results. As part of the certification process, and as a cross-check for the total sulphur, total carbon, NAG, and total metal tests to be conducted on site, it is proposed that duplicate samples of the material sent to the assay lab periodically be sent to an external laboratory for ABA and SFE testing, as well as elemental solid phase and whole rock analyses. Depending on how the results of these tests correlate with the results of total sulphur, total carbon, NAG, and total metal tests conducted on site, the decision criteria used to segregate the waste materials produced on site may be adjusted.

SECTION 4 • PREDICTED ARD/ML POTENTIAL OF STORED WASTE

As stated in section 2.0, excess waste material not used in construction will either report to an RSF or to the Portage pit for final disposal. Table 4-1 presents the volumes of waste rock and till that are expected to be used for various construction purposes, placed within an RSF, or placed into the Portage pit by operation year, based on the mine schedule prepared by AMEC (2005), modified such that approximately 8,500 tonnes of ore are processed per day. As shown on this table, it is expected that there will be an excess of UM rock available for capping the TSF and Portage RSF, and for the constructing the exteriors of Portage RSF cells, although the timing of its availability is such that the UM rock will need to be stored for use at end of mine life.

MEADOWBANK GOLD PROJECT

TYPE A WATER LICENSE APPLICATION

Along with the NP and AP data obtained for each rock type to date, these waste rock and till volumes were used to estimate the annual and cumulative ARD potential of each of the RSFs and the waste to be backfilled into the pit, based on NPR. These values were derived using the following equations:

Annual NPR =
$$\Sigma Sum NP_x * \%_x$$
), and $\Sigma (Sum AP_x * \%_x)$

Cumulative NPR =
$$(V_A/V_C) * \Sigma Sum NP_x * \%_x)$$
,
 $(V_A/V_C) * \Sigma (Sum AP_x * \%_x)$

Where:

x = rock type;

V_A = total annual volume to be placed in storage area; and

 V_C = total cumulative volume within storage area.

Tables 4-2 to 4-4 present these values. As shown in these tables, the material that will be stored in each of these areas is predicted to be NPAG on an annual basis.

Table 4-1: Portage Rock Storage Facility Bulk ARD Summary

Operation	Annual	Annual ARD	Annual Percentage of Waste Type (%)

MEADOWBANK GOLD PROJECT TYPE A WATER LICENSE APPLICATION

SECTION 5 • PERFORMANCE MONITORING

The water quality of the drainage from the RSFs and UM stockpile, and the Portage pit lake will be monitored during operation and post-closure. Details on the monitoring plan are provided in (MMC, 2007b).

SECTION 6 • REPORTING

The results of all of the testing completed on waste materials during operation at Meadowbank will be compiled and reported annually to the Nunavut Water Board (NWB) and NIRB. It is also proposed that the block model be updated on an annual basis with pit wall and/or drill core test results relating to ARD/ML potential, to ascertain whether any correlations can be made between these parameters and geologic variability within rock types for an enhanced ability to predict the quality of rock in advance of mining.

APPENDIX A

ARD/ML Potential of Meadowbank Mine Wastes

MEADOWBANK GOLD PROJECT

TYPE A WATER LICENSE APPLICATION

The acid rock drainage (ARD) and metal leaching (ML) potential of waste materials to be produced at Meadowbank has been evaluated through both static and kinetic testing. The static tests conducted for this purpose included the following:

- mineralogy;
- whole rock analysis;
- elemental solid phase analysis (multi-acid digestion);
- acid base accounting (ABA); and
- shake flask extraction (SFE).

Test methods and results are provided in (Golder, 2005a).

Kinetic testing was conducted on representative samples of waste rock from each lithology using standard 1 kg humidity cell tests, 100 kg composite column tests, and approximately 250 kg composite field cells. Test methods and results are provided in (Golder, 2005b).

Table A-1 summarizes the ARD/ML potential of the till, lake sediments and pit rock, based on the results of static and kinetic testing (Golder, 2005a and 2005b). ARD potential was evaluated by comparing ABA results to the guidelines presented in INAC (1992). ML potential was evaluated based on exceedances of the Metal Mining Effluent Regulations (MMER, 2002) in kinetic test leachate.

TABLE A 1: Summary of ARD/ML Potentials of Meadowbank Waste Types

Deposit	Waste Type	ARD Potential			MMER Metal
		% PAG	% Uncertain	% NPAG	Exceedances in Kinetic Test Leachate
-	Till	9	-	91	N/A
-	Lake Sediments	73	-	27	N/A
Vault	IV	11	14	75	None ¹
Portage/Goose	IV	20	14	66	None ¹
	IF	67	13	20	Zn
	UM	2	2	96	As
	QTZ	86	-	14	N/A

^{1.} Based on the results corresponding to the 100 kg composite sample (Golder, 2005b).

PAG - potentially acid-generating

NPAG - not potentially acid-generating

N/A – not analyzed

^{2.} Based on the results corresponding to the combined whole ore tailings composite (53% Third Portage, 8% Goose, 39% Vault) (Golder, 2005a).
