

APPENDIX B6- WATER QUALITY AND FLOW MONITORING PLAN, VERSION 3 (JULY 2014)

MEADOWBANK GOLD PROJECT

Water Quality and Flow Monitoring Plan

In Accordance with Water License 2AM-MEA0815

Prepared by:
Agnico Eagle Mines Limited – Meadowbank Division

Version 3
July 2014

EXECUTIVE SUMMARY

The Nunavut Water Board (NWB) has issued Type A Water License 2AM-MEA0815 to Agnico Eagle Mines Limited (AEM) for the Meadowbank Gold Project site authorizing the use of water and the disposal of waste required for mining and milling and associated uses.

As part of their Water License renewal application, AEM has revised Meadowbank's Water Quality and Flow Monitoring Plan (specified under Part I, Item 2 of the license), as presented here.

Section 2 in this Plan includes an overview of the monitoring programs and mine development schedule. Section 3 provides specific details (including sample locations and parameters to be measured) for the compliance monitoring program, along with general guidance for the event monitoring program. An adaptive management program is described for both regulated discharge and non-regulated discharge in Section 3 as well. Requirements of the flow monitoring program are described in Section 4, and an overview of the reporting requirements in Section 5.

IMPLEMENTATION SCHEDULE

As required by Water License 2AM-MEA0815, Part B, Item 16, the proposed implementation schedule for this Plan is outlined below.

This Plan will be immediately implemented (July 2014) subject to any modifications proposed by the NWB as a result of the review and approval process.

SECTION 1. INTRODUCTION

The Water Quality and Flow Monitoring Plan (the Plan) has been prepared in accordance with the requirements of the Nunavut Water Board Type A water license # 2AM-MEA0815. The Plan is one component of the *Aquatic Effects Management Program* (AEMP) and is closely associated with the *Water Management Plan*. The implementation and periodic updates to this Plan are the responsibility of the Meadowbank Environment Department under the guidance of the Meadowbank Environment Superintendent.

The Plan summarizes the monitoring locations, sampling frequency, monitored parameters, compliance discharge criteria and an adaptive management plan for water quality at the Meadowbank Gold Project.

The purpose of this Water Quality and Flow Monitoring Plan is to establish the program to be implemented and followed by AEM's Meadowbank environmental management team to monitor the performance of the waste and water management systems at the Meadowbank Gold Project. The program includes:

- Verifying and validating the predicted water quality values with empirical measurements of the mine site water quality and flows;
- A comparison of measured water quality data to compliance requirements stipulated in the Nunavut Water Board Type A water license # 2AM-MEA0815; and
- A framework for adaptive management that allows the identification and rectification, where necessary, of unexpected trends or non-compliance in water quality and flows.

The Plan provides information on the locations of the monitoring stations at the various stages of mining. These monitoring locations are used to evaluate the performance of the mine waste and water management system.

The objectives of the monitoring program are:

- 1) to track the chemistry of the contact and non-contact water prior to and during discharge;
- 2) to assist in identifying if water treatment is required prior to discharge; and
- 3) to minimize the potential impacts of mining activities on the surrounding environment.

Additional locations outside the footprint of the mine (and outside the scope of this Plan) will be monitored under the *Meadowbank Gold Project Aquatic Effects Management Program and the Core Receiving Environmental Monitoring Plan (December 2012)*.

SECTION 2. OVERVIEW

2.1 OVERVIEW OF SITE WATER MANAGEMENT PLAN

Details of the water management plan are discussed in the *Meadowbank Water Management Plan* which is updated annually. All contact water from the mine facilities including the Portage and Vault waste rock storage facilities, open pits, and other disturbed areas will be directed by pumping or berms and other surface diversions to either of the following:

- Sumps from which the water will be pumped to either the Portage or the Vault Attenuation Pond prior to discharge, or the Reclaim Pond if required; or
- The open pits during reflooding and following the cessation of mining.

As specified in the *Water Management Plan*:

"All contact water will be intercepted, contained, analysed, treated, if required, and discharged to the receiving environment when water quality meets the discharge criteria."

2.2 MONITORING PROGRAMS

This Plan has been divided into two levels of investigation to characterize the range of impacts between the sources of contact water in the individual mine facilities and the point of discharge or release of contact water to the receiving environment. The two levels of monitoring include:

- 1) compliance monitoring; and
- 2) event monitoring.

2.2.1 Compliance Monitoring Program (CM)

The CM sites are those stipulated in the water license; these sites vary from contact water collection ditches and attenuation ponds to sampling in areas prior to discharge to the receiving environment. The requirements of the water license including water quality limits will be applied at the mine discharge points identified in the CM program.

The CM program provides a mechanism to assess water quality at specified sites, to confirm and document compliance of discharge with regulatory requirements. As part of adaptive water management, these internal monitoring stations provide protection to the receiving water environment, provide data to predict pit reflooding water quality and ensure exceedences of predicted or regulated levels are appropriately managed or mitigated to reduce impacts.

2.2.2 Event Monitoring Program (EM)

The EM sites result from unexpected events such as spills, accidents, and malfunctions. The response programs for such events are discussed in greater detail in the following two documents:

- Meadowbank Gold Project Spill Contingency Plan (November 2013); and
- Meadowbank Gold Project Emergency Response Plan (August 2013).

Each accidental release will require mobilization of site equipment to stabilize the release, procedures to contain, neutralize, and dispose of the discharge, and recommendations for monitoring the site following the incident.

2.3 OVERVIEW OF MINE DEVELOPMENT SCHEDULE

Mining activity at the Meadowbank Gold Project is projected to progress from the south, in the area of the Goose and Portage pits early in the mine life (Years 1 to 6), then northward to the Vault Pit towards the end of mine life (Years 4 to 7). The staged mine development results in the southern pits being completely mined out and undergoing closure during the operational phase of the Vault Pit, while the mill and tailings storage facility operate throughout the mine life. It is for this reason that the monitoring sites change with time as the mining operations progress. Figures 2-1, 2-2, 2-3 and 2-4 show the sequence of staged development of the mine, from the early operational to the late operational, closure and post-closure phases, respectively. The actual configuration of the pits has changed as mining progresses. As a result, the monitoring program (Section 3.0) accommodates changes in the pit designs which may include one or more ponds during the filling phase before the single Portage Pit Lake develops from the Portage pits. Figure 2-5 depicts the Meadowbank Gold Project facilities in the Hamlet of Baker Lake.

The staged development of the mine facilities has been divided into five phases for monitoring purposes. The five phases include:

- Pre-development and Construction phase;
- Early operational phase;
- Late operational phase;
- Closure phase; and
- Post-closure phase.

As the mine is now entering the late operational phase, monitoring associated with pre-development/construction and early operations are largely complete. A summary of site activities and water quality monitoring issues during these phases is provided below.

2.3.1 Pre-development and Construction Phase

The principal impact resulting from construction activities has been the increase in turbidity and TSS in the Second Portage and Third Portage lakes from the release of particulates from dike construction material, surface runoff, the disturbance of lake sediments and the dewatering of future mining zone. Management and monitoring of these impacts are discussed in the AEMP.

2.3.2 Early Operations Phase

During the early operations phase, mining has occurred in the Goose and Portage pits. Most of the waste rock generated from the pits is delivered to the Portage waste rock storage facility (RSF), however some waste rock are used for construction of mine infrastructure (roads, dikes), and some has been used to backfill Portage Pit. Mill tailings are directed into the tailings storage facility (TSF) for final disposal. Tailing has been discharged in the North cell and will be discharged into the south cell around October 2014. During the early operations phase, mine water from the individual pit sumps including dike seepage are pumped to the Portage Attenuation Pond. Water from the Portage Attenuation Pond is discharged to Third Portage Lake during open water season on an annual basis thru a diffusor (Years 1 to 4). Water

contained in the Attenuation pond (south cell) is used as process water or is treated for TSS prior being discharged. Process water for the Process Plant is recycled from the Reclaim Pond in the TSF and is not discharge to the receiving environment. In closure, reclaim water will be discharged to either the Portage or Goose Island pit lakes while the dewatering dikes are still in place.

2.3.3 Later Operations Phase

Mining in the Goose and Portage pits will be completed in Year 7 after which the pits will be flooded by natural inflows and water transferred on a controlled basis from Third Portage Lake. Current mine plans estimated Portage and Goose pit entire flooding sequence to be completed by the beginning of 2025 (Meadowbank Gold Project Water Management Plan 2013). Ultramafic waste rock will be used to progressively cap the Portage RSF and the TSF for closure.

Mining will take place in the Vault Pit during the late operations phase with waste rock delivered to the Vault RSF and ore to the mill in the Portage area. Vault area tailings will be deposited in the Portage TSF. Runoff and infiltration drainage from the Vault RSF, dike seepage and Vault area contact water will be collected in the Vault Attenuation Pond prior to discharge to Wally Lake.

2.3.4 Closure Phase

During the closure phase, it is anticipated that mining will have ceased in the Vault Pit and the pit will be allowed to flood using natural inflows and water transferred on a controlled basis from Wally Lake. Current estimates are that it will take about 6 years for the Vault Pit to completely flood by which time the Vault Attenuation Pond and the Pit Lake will have merged. There are currently no plans to cap the Vault RSF as it is not expected to generate acid rock drainage.

By the end of the late operational phase or early in the closure phase the Portage and Goose pits will be completely flooded and the remaining portions of the TSF capped.

2.3.5 Post Closure Phase

Activities during the post-closure phase are primarily monitoring of selected mine facilities including flooded pit lakes and the reclaimed TSF. The Goose and Vault Dikes will be breached once water quality within the pit lakes meets discharge criteria.

2 After October 2014, the Reclaim Pond is relocated to the South Cell TSF. After this date, there is no Attenuation Pond.

SECTION 3. MONITORING PROGRAM

The monitoring program is presented in three sections; requirements of the compliance monitoring program, an overview of the event monitoring program, and then details of the adaptive management program for monitoring results.

3.1 COMPLIANCE MONITORING PROGRAM

The CM program monitors the chemistry of mine contact water and diverted water at specified locations prior to release into the receiving water environment in order to confirm and document compliance with regulatory requirements. The types of water and the timing of the CM program include:

- non-contact water discharged from diversion ditches during operations, and closure phases of the mine and eventually non-contact water from dike seepage;
- mine contact water directed to and discharged from Attenuation Ponds during the operations phase of the mine;
- monitoring points located within the pit lakes before and after the dikes have been breached during the post closure phase of the mine life; and
- runoff from the Tailings Storage Facility after closure.

The CM sampling program has multiple monitoring stations across the project site, with sampling at different stages of the mine life. All of the CM stations, a description of their location, parameters to be monitored and sampling frequency are listed in Table 3-1. Specific details for the monitoring parameter groups are provided in Table 3-2. In summary, AEM proposes 6 groups of parameters, as identified in Meadowbank's Type A Water License Schedule I Table 1. These include:

- Group 1 – mine site monitoring parameters; includes the former Groups 2 and 3 and all parameters identified in SNC (2014) water quality predictions for contaminants that may require treatment including total cyanide, copper and ammonia;
- Group 2 – receiving environment parameters consistent with the CREMP and applied to all AEMP stations (including ground water monitoring); includes dissolved metals to be protective of the aquatic environment;
- Group 3 – sampling prior to discharge; includes MMER parameters plus sulphate, turbidity and Al;
- Group 4- sampling prior to discharge at secondary containment fuel storage areas in Baker Lake and Meadowbank;
- MMER – unchanged; and
- Full Suite – Group 2, plus total petroleum hydrocarbons and turbidity.

Figures 2-1, 2-2, 2-3, 2-4 and 2-5 show the approximate location of each of the sampling sites. The actual location of each sampling site are determined by access and safety considerations and are marked by a stake that defines the exact location of the collection point for sampling events with appropriate attached signage in English, Inuktitut and French.

GPS coordinates for all compliance monitoring stations were confirmed with the AANDC water inspector, as required in Part I, Item 7 of the NWB Type A water license.

3.1.1 General Sampling and Analysis Program

Surface grab samples or samples from diversion ditches and piped discharge points are collected in clean laboratory-supplied containers and preserved as directed by the analytical laboratory. During all phases, samples are analyzed offsite at an accredited commercial lab (ALS in Burnaby BC, Maxxam Analytics in Montreal or Multi-Lab Direct in Val d'Or).

Table 3-3 summarizes the minimum sample volumes, container, preservation, and holding times for each analyte. This information is from the *USEPA Methods for Chemical Analysis of Water and Waste Water (EPA-600/4-79-020, 1979)*.

Table 3-2: Monitoring Parameters

Group	Parameters
1	pH, turbidity, hardness, alkalinity, ammonia, ammonia nitrogen, total metals (aluminum, arsenic, barium, cadmium, chloride, chromium, copper, fluoride, iron, lead, manganese, mercury, molybdenum, nickel, nitrate, selenium, silver, thallium, zinc) sulphate, total dissolved solids (TDS), TSS, total cyanide
2	Total and Dissolved metals: aluminum, antimony, arsenic, boron, barium, beryllium, cadmium, copper, chromium, iron, lithium, manganese, mercury, molybdenum, nickel, lead, selenium, tin, strontium, titanium, thallium, uranium, vanadium and zinc Nutrients: Ammonia-nitrogen, total kjeldahl nitrogen, nitrate nitrogen, nitrite-nitrogen, ortho-phosphate, total phosphorous, total organic carbon, total dissolved organic carbon and reactive silica; Conventional Parameters: bicarbonate alkalinity, chloride, carbonate alkalinity, conductivity, hardness, calcium, potassium, magnesium, sodium, sulphate, pH, total alkalinity, TDS, and TSS, turbidity; Total cyanide and free cyanide.
3	MMER parameters (total cyanide, arsenic, copper, lead, nickel, zinc, radium 226, total suspended solids, pH), sulphate, turbidity and total aluminium.
4	Total Arsenic, Total Copper, Total Lead, Total Nickel, TSS, Ammonia, Total Cyanide, Benzene, Toluene, Ethylbenzene, Xylene, TPH, Oil & Grease, pH
MMER	total cyanide, arsenic, copper, lead, nickel, zinc, radium 226, total suspended solids, pH, effluent volumes and flow rate of discharge, acute toxicity, Daphnia Magna and environmental effects monitoring (EEM).
Full Suite	Group 2, Total Petroleum Hydrocarbons, Turbidity

Table 3-3: Summary of Sampling Requirements for each Analyte

Parameter	Minimum Volume (ml)	Bottle Type	Preservation	Holding Time
pH	250	250 mL, glass or plastic, filled to the top	4°C	Analyze immediately
Conductivity	125	250 mL, glass or plastic	4°C	28 days
Hardness	250	250 mL plastic, filled to the top	4°C, HNO ₃	6 months
Oil and Grease (total)	1000	1 L amber glass	4°C, H ₂ SO ₄	28 days
Turbidity	125	250 mL, glass or plastic	4°C	48 hours
Total Dissolved Solids (TDS)	125	250 mL glass	4°C	7 days
Total Suspended Solids (TSS)	125	250 mL glass	4°C	7 days
Total Alkalinity	250	250 mL, glass or plastic, filled to the top	4°C	14 days
Bicarbonate Alkalinity	250	250 mL, glass or plastic, filled to the top	4°C	14 days
Carbonate Alkalinity	250	250 mL, glass or plastic, filled to the top	4°C	14 days
Total Cyanide	125	250 mL, glass or plastic	4°C, NaOH	14 days
Free Cyanide	125	250 mL, glass or plastic	4°C, NaOH	14 days
Benzene, Toluene, Ethylbenzene & Xylene (BTEX)	40 (per vial)	3 X 40 mL, glass, filled to the top	4°C	7 days
Total Petroleum Hydrocarbons(TPH)	1000	1L, glass	4°C, H ₂ SO ₄	28 days
<u>Total Metals (ICP-MS)</u> (Aluminum, Antimony, Arsenic, Boron, Barium, Beryllium, Cadmium, Cobalt, Copper, Chromium, Iron, Lithium, Manganese, Mercury, Molybdenum, Nickel, Lead, Selenium, Tin, Strontium, Titanium, Thallium, Uranium, Vanadium, Zinc, Potassium, Magnesium, Sodium)	125	250 mL plastic	4°C, HNO ₃	6 months
<u>Dissolved Metals</u> (Aluminum, Antimony, Arsenic, Boron, Barium, Beryllium, Cadmium, Cobalt, Copper, Chromium, Iron, Lithium, Manganese, Mercury, Molybdenum, Nickel, Lead, Selenium, Tin, Strontium, Titanium, Thallium, Uranium, Vanadium, Zinc)	125	250 mL plastic	4°C, Filtered on-site, HNO ₃	6 months

Ammonia-nitrogen	250	250 mL, glass or plastic, filled to the top	4°C, H ₂ SO ₄	28 days
Total kjeldahl nitrogen	250	250 mL, glass or plastic, filled to the top	4°C, H ₂ SO ₄	28 days
Nitrate nitrogen	125	250 mL, glass or plastic	4°C	48 hours
Nitrite nitrogen	125	250 mL, glass or plastic	4°C	48 hours
Ortho-phosphate	125	250 mL, glass or plastic	4°C	14 days
Total phosphorous	125	250 mL, glass or plastic	4°C, H ₂ SO ₄	28 days
Total organic carbon	125	250 mL glass	4°C, H ₂ SO ₄	28 days
Dissolved organic carbon	125	250 mL glass	4°C, H ₂ SO ₄	28 days
Chloride	125	250 mL, glass or plastic	4°C	28 days
Fluoride	125	250 mL plastic	4°C	28 days
Sulphate	125	250 mL, glass or plastic	4°C	28 days
Radium 226	500	1L plastic	4°C, HNO ₃	1 month
Reactive Silica	250	500 mL, plastic	4°C	28 days

3.1.2 Compliance Monitoring Stations and Discharge Criteria

Further details of the specific CM stations and discharge criteria stipulated under the Nunavut Water Board Type A Water License are provided below.

3.1.2.1 Construction and Dewatering Activities

In order to mine the ore in the Portage, Goose and Vault pits, a series of dikes have been built to isolate the pits from the surrounding water bodies. The pits, and the corresponding tailings impoundment area, have been dewatered to allow access to these areas. The document "*Water Quality Monitoring and Management Plan for Dike Construction and Dewatering at the Meadowbank Mine (April 2010)*" has been prepared to specifically address the monitoring requirements for these activities.

CM stations ST-DC or equivalent and ST-DD or equivalent monitored the dike construction and dewatering activities. As stipulated in Part D, Section 15 of the water license, TSS levels at these stations have been compared to the maximum monthly mean and short term maximum values presented in Table 3-4.

Table 3-4: TSS Criteria at CM Stations ST-DC and ST-DD

Parameter	Maximum Monthly Mean (mg/L)	Short Term Maximum(mg/L)
TSS in areas where there is spawning habitat and at times when eggs or larvae are expected to be present (applied at monitoring stations located closest to the high value shoal areas starting Sept 1,2008)	6	25

TSS in all other areas and at times when eggs/larvae are not present	15	50
TSS in impounded areas (e.g. northwest arm of second portage lake) at all times in all areas.	15	50

As the dewatering process took place, mitigation measures were put in place to ensure that effluent from CM stations ST-DD or equivalent didn't exceed the parameter concentrations presented in Table 3-5, as stipulated in Part D, Section 16 of the water license.

Table 3-5: Effluent Criteria at CM Station ST-DD

Parameter	Maximum Monthly Mean	Short Term Maximum
Total Suspended Solids	15.0 mg/L	22.5 mg/L
Turbidity	15 NTU	30 NTU
pH	6.0 to 9.0	6.0 to 9.0
Total Aluminum	1.5 mg/L	3.0 mg/L

All surface runoff during the construction of any facility at the Meadowbank Gold Project, where water flow may directly or indirectly enter a water body, shall not exceed the TSS water quality limits presented in Table 3-6, as stipulated in Part D, Section 24 of the water license.

Table 3-6: TSS Criteria for All Surface Runoff during the Construction of Any Facility

Parameter	Maximum Average Concentration (mg/L)	Maximum Concentration of Any Grab Sample (mg/L)
Total Suspended Solids	50.0	100.0

3.1.2.2 Water Collection System

A water collection system comprised of ditches, sumps, attenuation ponds and open pits has been developed to control surface water at the Meadowbank project. Water that may potentially come into contact with waste rock, tailings or contaminated material is segregated from non-contact water and collected in the Attenuation ponds and treated, if necessary, prior to discharge into the receiving environment. As discussed above, this water might be used as process water.

The design of the ditches is based on the assumption that drainage can be achieved by gravity flow; the design for the sumps and ponds assumes that all inflows can be achieved by gravity. As a result, this infrastructure is considered as low maintenance. However, regular monitoring during freshet (the snowmelt, thawing and freshet ice-free season) and during heavy or prolonged rainfall to identify any issues with regards to:

- The configuration or structure of channels, due to localized thawing, local ground instabilities, subsidence and transport of fine particles;

- The free flow of water, due to an accumulation of ice, sediments and other debris; and
- Potential damage to retention structures and monitoring of seepage.

Maintenance operations should consist of cleaning accumulated sediments and debris from the ditches and culverts, and repairing damaged areas as soon as possible. Removed sediments should be stockpiled for channel maintenance purposes or disposed of in the tailings impoundment.

The pumping systems (pump and connected piping) to be used for site water management structures are sized to have a sufficient capacity for dewatering the maximum pond volume within a one week period, provided the water to be discharged is of suitable quality. Pumps are operated based on the quality and volume of water accumulated within the ponds. Particular attention is required in this maintenance program to ensure that no water freezes in the pump system. No water should be allowed to sit in the pumps or piping system when temperatures are near, or below, +1 degrees Celsius.

During pit flooding, samples will be taken in representative locations of the pit that is being reflooded. It is likely that the sampling sites will change based on mine sequencing and as the water level in the pits rise in response to flooding. It is anticipated that during the early flooding phase of the Portage Pit, water may accumulate in more than one area of the pit (Section 2.3). The current monitoring program assumes separate samples will be collected from ponds in the North Portage and the South Portage pits during flooding and prior to the two water bodies merging.

The following is a list of the various areas of the water collection system at the Meadowbank mine where samples for the compliance monitoring program are being or will be collected:

- Portage and Goose Island ditches, sumps, ponds and pit lakes (ST-5; ST-6; ST-8; ST-9; ST-12; ST-17; ST-19; ST-20, ST-22);and
- Vault area ditches, sumps, ponds and pit lake (ST-10; ST-13; ST-23, ST-25).

Effluent discharged from the Portage Attenuation Pond at CM station ST-9 is directed to Third Portage Lake through the Third Portage Lake Outfall Diffuser and shall not exceed the effluent quality limits presented in Table 3-7, as stipulated in Part F, Section 2 of the water license.

Table 3-7: Effluent Criteria at CM Station ST-9

Parameter	Maximum Average Concentration	Maximum Allowable Grab Sample Concentration
pH	6.0 to 9.0	6.0 to 9.0
TSS (mg/L)	15	30
Turbidity (NTU)	15	15
Total (T)-Al (mg/L)	1.5	1.5
Dissolved (D)-Al (mg/L)	1.0	1.0
T-As (mg/L)	0.30	0.60
T-Cd (mg/L)	0.002	0.004
T-CN	0.5	1.0
T-Cu (mg/L)	0.1	0.2
T-Hg (mg/L)	0.0004	0.0008

NH ₃ -N (mg/L)	16	32
T-Ni (mg/L)	0.2	0.4
T-NO ₃ -N (mg/L)	20	40
T-Pb (mg/L)	0.10	0.20
T-P (mg/L)	1.0	2.0
T-Zn (mg/L)	0.4	0.8
T-Cl- (mg/L)	1000	2000
Total Petroleum Hydrocarbons (TPH) (mg/L)	3	6

Effluent discharged from the Vault Attenuation Pond at CM station ST-10 shall be directed to Wally Lake through the Wally Lake Outfall Diffuser and shall not exceed the effluent quality limits presented in Table 3-8, as stipulated in Part F, Section 3 of the water license.

Table 3-8: Effluent Criteria at CM Station ST-10

Parameter	Maximum Average Concentration	Maximum Allowable Grab Sample Concentration
pH	6.0 to 9.0	6.0 to 9.0
TSS (mg/L)	15	30
Turbidity (NTU)	15	15
Total (T)-Al (mg/L)	1.5	3.0
Dissolved (D)-Al (mg/L)	1.0	2.0
T-As (mg/L)	0.1	0.2
T-Cd (mg/L)	0.002	0.004
T-Cu (mg/L)	0.1	0.2
T-Hg (mg/L)	0.004	0.008
NH ₃ -N (mg/L)	20	40
T-Ni (mg/L)	0.2	0.4
T-NO ₃ -N (mg/L)	50	100
T-Pb (mg/L)	0.10	0.20
T-P (mg/L)	1.5	3.0
T-Zn (mg/L)	0.2	0.4
T-Cl- (mg/L)	500	1000

Effluent discharged from CM stations ST-9 and ST-10 shall be demonstrated to be non-acutely lethal, as stipulated in Part F, Section 24 of the water license. The following are the toxicity tests that are performed:

- Reference Method for Determining Acute lethality of Effluents to Rainbow Trout EPS 1/RM/13 Second Edition December 2000 (with May 2007 amendments); and
- Biological Test Method; Acute Lethality Test Using Daphnia spp. EPS 1/RM/11 July 1990 (with May 1996 amendments).

All water collected within the non-contact water diversion system during operations at CM stations ST-5 and ST-6, as well as East Dike seepage (ST-8) shall not exceed the effluent quality limits presented in

Table 3-9, as stipulated in Part F, Section 4 in the water license.

Table 3-9: TSS Criteria at CM Stations ST-5, ST-6 and ST-8

Parameter	Maximum Average Concentration (mg/L)	Maximum Allowable Grab Sample Concentration (mg/L)
TSS	15	30

3.1.2.3 Tailings Storage Facility and Reclaim Pond; Portage and Vault Waste Rock Storage Facilities

Concurrent reclamation is planned for the TSF during the late operations phase of the mine using non-acid generating ultramafic waste rock. The current cap design includes a sloped surface to promote runoff and catchment devices to capture the runoff from the TSF. Sampling of the TSF cap runoff will be conducted in either ditches or sumps adjacent to the TSF.

The reclaim pond is designed to migrate southward as the TSF fills with tailings and eventually combine with the Portage Attenuation Pond. Samples are collected from the open water of the reclaim pond by the floor of the reclaim barge.

At the end of mine life, water in the reclaim pond will be drained to complete the reclamation of the TSF. Reclaim water will be transferred to the Goose Island Pit Lake, which, at that time, will still be isolated from adjacent open waters by the dewatering dikes. Reclaim water quality will be monitored during operation and may be treated prior to release to the pit lakes. The Goose Island Dike will be breached after reclaim water has been released to the pit lakes and water quality has met the appropriate discharge criteria. The discharge criteria, including CCME freshwater aquatic life guidelines where available, ambient lake concentrations and/or other risk-based assessment criteria, will be determined through aquatic effects studies and/or an approval process initiated through the Nunavut Water Board and KIA.

Waste rock from the open pits not used for site development purposes will be trucked to mine waste rock storage facilities (RSF); two RSF areas will be used, one near the Portage and Goose Island pits and another near the Vault pit. Excess waste rock is also placed within the Portage pit to be submerged during pit re-flooding. Monitoring in these areas is included in the CM water collection system discussed in Section 3.1.2.2.

The following is a list of the various areas where samples associated with the TSF and RSF for the compliance monitoring program are to be collected:

- Tailings reclaim pond (ST-21); and TSF drainage run-off at closure (ST-22); and
- Portage waste rock storage facility if water is observed at these areas (ST-16).

3.1.2.4 Support Facilities

Mine Site

A rotary biological contactor (RBC) sewage treatment plant is in operation at the Meadowbank mine site. Discharge from the plant is directed to Storm water management pond and then get pumped in the TSF. Water quality monitoring for this facility is included in the CM water collection system.

The landfill is constructed at the Meadowbank mine within the catchment of the Portage RSF. Only inert waste material consisting of primarily construction and non-organic domestic waste is disposed of at this facility. Hazardous wastes are stored on site in a waste containment area, and transported annually during the sea lift to an appropriate hazardous waste disposal facility in southern Canada. Further details for these waste facilities can be found in the *Landfill Design and Management Plan (March 2013)* and the *Hazardous Material Management Plan (October 2013)*.

A landfarm has been built on site to treat petroleum hydrocarbon contaminated soils beginning in 2012. Monitoring is conducted for the water accumulating within the containment berm from July to October. In the event of water accumulation, the ponded water will be analyzed as described in Part F, Item 23 of the water License prior to discharge to the adjacent Tailing Storage Facility. Further details for the landfarm facility can be found in the *Landfarm Design and Management Plan (February 2013)*.

A 5.6 million liter bulk fuel storage tank is located at the Meadowbank mine site. Runoff water from within the containment area is collected within the tank's secondary containment enclosure that is equipped with HDPE liner. Water collected is discharged to land, when necessary, in a controlled manner. Effluent from the fuel containment facilities being discharged to land (sampled as ST-37) shall not exceed the effluent quality limits presented in Table 3-10, as stipulated in Part F, Section 23 of the water license.

Baker Lake Marshalling Area

Surface water runoff from the bulk fuel tank storages area is collected within the tank's secondary containment enclosures that are equipped with HDPE liner; these are designed to contain petroleum products released due to spill events. Water collected in the secondary containment enclosures CM station ST-38 and ST-40 is discharged to land in a controlled manner according to the Nunavut Water Board Type A water license # 2AM-MEA0815.

All effluent being discharged from the secondary containment enclosures at the Baker Lake marshalling facility shall not exceed the effluent quality limits presented in Table 3-10, as stipulated in Part F, Section 23 of the water license.

Table 3-10: Effluent Criteria at CM Station ST-37 to ST-40

Parameter	Maximum Average Concentration	Maximum Concentration of Any Single Grab Sample
pH	6.0 – 9.5	6.0 – 9.5
Total Arsenic (mg/L)	* *0.5	1.00
Total Copper (mg/L)	**0.30	0.60
Total Nickel (mg/L)	**0.50	1.00
Total Zinc (mg/L)	*0.50	1.00
TSS (mg/L)	* 15.0	30.0
Total Cyanide	*0.1	0.2
Benzene (ug/L)	370	370
Toluene (ug/l)	2	2
Ethylbenzene (ug/L)	90	90
Lead (mg/L)	0.1	0.1
Oil and Grease (mg/L)	5.0 and no visible sheen	5.0 and no visible sheen

3.1.2.5 All Weather Private Access Road (AWPAR) and Quarries

The AWPART extends 108 km between the Hamlet of Baker Lake and the Meadowbank Project site. Twenty two (22) quarries along the AWPART were used to construct the road; some of these quarries will remain open for the duration of the mine life to service the road. There is also 1 quarry at Meadowbank mine on the East side of the airstrip to provide rock fill for the mine site roads and building pads. Monitoring procedures along the AWPART and quarries include visual inspections of infrastructure and water quality sampling.

Visual Inspections

The watercourse crossing visual inspection and maintenance program is designed to identify issues relating to watercourse crossings structural integrity and hydraulic function. It has three main objectives:

- 1) Visual inspection of its infrastructure to identify defects, cracks or any other risks to structural integrity. Particular attention will be paid to the inlet and outlet structures of culverts, and to bridge abutments and their foundations, as required. This inspection is conducted annually by a geotechnical engineer.
- 2) Visual inspection to identify sediment or other debris accumulation impeding the free flow of water through the crossings. Maintenance operations will consist of hand removal of accumulated debris and repairing damages as soon as possible. This inspection is conducted twice annually, during and post freshet season, by a member of the Meadowbank environmental team.
- 3) Visual inspection of upstream and downstream channel to identify bed erosion or scour around the watercourse crossing structure. Particular attention is to be paid to bridge abutments and abutment foundations as they are vulnerable to scour and erosion. This inspection is conducted twice annually, during and post freshet season, by a member of the Meadowbank environmental team.

Results of these inspections are reported in the AEM annual report.

Water Quality Monitoring

Rock quarry geochemistry studies were conducted prior to construction. The results indicated that there are not expected to be any adverse water quality issues associated with the quarried rock¹. In June 2008 an additional water quality monitoring and geochemical characterization study was completed at each of the quarries. Results were presented in the AEM 2008 Annual Report; the study concluded that there was no evidence of any significant acid generation or metal leaching issues associated with the 22 road quarries.

Throughout the open water seasons of 2007 and 2008, water seeps and water ponded in contact with the road were collected along the full length of the AWPART in addition to samples upstream and downstream of the 9 major stream crossings. Results were similar between years and indicate naturally elevated metals concentrations in a number of the streams. Overall, the results suggest low risks to aquatic life.

¹ *Geochemical Assessment of Potential Quarry Rock Along the Proposed Mine Access Road, Meadowbank Project Nunavut, Golder, 2007;*

Assessment of the Acid rock Drainage and Metal Leaching Potential of Rock from Potential Quarry Site Pit 6, Meadowbank Project Nunavut, Golder 2007;

Assessment of the Acid Rock Drainage and Metal Leaching Potential of Rock Samples Collected from an Esker along the Tehek Lake Access Road, Meadowbank Project, Nunavut, Golder 2007.

Consequently, the water quality monitoring program has been amended to reflect these conclusions. On an annual basis visual inspections for turbidity or instability are conducted during freshet. If issues are observed or a spill occurred near a water course during the winter a full suite of water quality sampling is conducted along the AWPAR at areas of concern. This includes:

- Any significant water seeps and/or water ponded in contact with the road. Other criteria for selecting a sampling location include: areas of evident rock staining (rust color particularly) and areas where an accidental spill has previously occurred.
- Upstream and downstream from the major road stream crossings in order to confirm there are no water quality issues resulting from these crossings or the adjacent road rock fill.

Water samples are sent to an accredited laboratory and analyzed for the following parameters: pH, hardness, conductivity, TSS, oil and grease, sulphate, explosive residues (nitrate and ammonia) and the following total and dissolved metals: aluminum, arsenic, cadmium, chromium, copper, fluoride, iron, mercury, molybdenum, nickel, lead, selenium, silver, thallium and zinc and if deemed necessary, TPH, heavy oils and BTEX.

In addition, pH, conductivity and turbidity (as a surrogate for TSS) are measured in the field at the time of visual inspections and water collection.

Should the results indicate a significant change in water quality from previous years or elevated risks to aquatic life, further water quality monitoring will be conducted at those specific locations to determine the cause. An action plan will be developed and implemented should the results indicate issues. The results for all access road water quality monitoring are reported in the AEM Annual Report.

The habitat compensation monitoring program for R02 compensation structures is described in the *Meadowbank Habitat Compensation Monitoring Plan (AEM, 2014)*. This monitoring program includes detailed habitat compensation sampling for the AWAR and mine site.

3.1.2.6 Seeps

Site specific empirical data for seeps from the RSFs, pit walls, and dikes are used to characterize the hydrochemistry and volumes of seasonal water flows and to calibrate and validate the water quality model (recently updated in SNC, 2014 "Water Quality Forecasting update for 2013-2015).

Water samples are collected from discharge points where seeps are found, according to the requirements for CM stations ST-S-2 (Saddle Dam seepage), ST-S-3 (South Camp dike seepage), ST-S-4 (Bay-Goose dike seepage) to ST-S-TBD (to be assigned as necessary). If seeps or ponds are observed at the toe of the Portage and/or Vault RSF, samples are or will be taken and monitored according to the water license. In summary, current sampling locations include:

- Seeps at or near the toe of the Portage RSF (ST-16; see Section 3.1.2.3); and
- Seeps in the faces or at the base of the Goose Island Dike, Bay Zone Dike, Central Dike, Vault Dike, and South Camp Dike (ST-S-2, ST-S-3, and ST-S-4).

In addition, seepage observations are to be characterized and monitored in accordance with Part I, Sections 8 and 15 of the water license, as presented in Table 3-11.

Table 3-11: Seepage Observations and Characterization

Characterization of seepage including: precise location; discharge rates and volumes; respective hazard(s) and consequences and prescribed mitigative measure	Minimum Frequency of Observation
Lake water Seepage Through Dewatering Dikes	Monthly
Seepage (of any kind) Through Central Dike	Monthly
Subsurface Seepage and Surface Runoff from Waste Rock Piles, TSF into ST-16 and Assay road seepage	Weekly during freshet; Quarterly otherwise
Seepage at Pit Wall and Pit Wall Freeze/Thaw and Permafrost Aggradation	Quarterly

In 2013, AEM obtained an amendment to Meadowbank's Type A Water License to discharge water from the East Dike seep as non-contact water. This location is now sampled as ST-8 (formerly ST-S-1) and required to meet the criteria for TSS in non-contact water as described in Section 3.1.2.2.

3.1.2.7 Groundwater

Groundwater quality data is used to predict the future quality of water that will accumulate in the pits during operation, and to determine baseline groundwater quality underneath the tailings basin (the northwest arm of Second Portage Lake) before tailing deposition. To this end, groundwater monitoring were installed to sample talik water (unfrozen ground beneath large lakes) in areas where through taliks exist. No groundwater monitoring wells will be installed at the Vault deposit as the Vault pit is developed in an area where the talik does not extend down through the permafrost.

The *Groundwater Monitoring Plan (January 2014)* describes the groundwater monitoring activities at the Meadowbank Gold Project. Water quality in the groundwater wells is monitored in accordance with the sampling requirements for CM stations ST-GW-1 to TBD.

3.1.2.8 Receiving Environment

Receiving water quality monitoring is discussed in Section 1A of the *Aquatic Effects Management Program (AEMP) (December 2012)*. Within the AEMP are numerous monitoring programs: of greatest emphasis for the protection of the aquatic environment are the core receiving environment monitoring program (CREMP), Environmental Effects Monitoring studies and targeted monitoring programs.

The core monitoring program includes two areas of sampling stations that surround each of the mine developments (near field and far field) for early detection of mine-related impacts. The monitoring program is summarized in Table 6.1 of the AEMP and includes: water quality, sediment chemistry, benthos, periphyton, phytoplankton, and fish monitoring (as part of EEM and fish habitat compensation monitoring), the parameters to be measured, sampling locations, sampling frequency, sampling methods, and criteria for data evaluation. Targeted studies are limited in scope and intended to address "specific questions related to particular components of mine development during construction and operation." In addition to, or superseding, the monitoring requisites in the AEMP, the water quality samples collected under this program are to be monitored in accordance with the requirements for CM stations ST-AEMP-1 to TBD and according to the CREMP design document (AEM, 2012). In 2013, AEM has also added NP-2, NP-1, Dogleg, and TPN basin AEMP stations.

A water quality monitoring program is also defined in the AEMP for discharge events during operations of

the Portage and Vault attenuation ponds. During the first 6 years of mine operation, it is necessary to discharge water from the Portage Attenuation Pond to Third Portage Lake and during the later years of mine operations, water may be discharged annually from the Vault Attenuation Pond to Wally Lake. CM stations ST-MMER-1 to TBD stipulate the monitoring requirements for these effluent outfalls. Monitoring locations for the effluent outfall diffusers for Third Portage and Wally lakes are to be located at the edge of the 30-m radius mixing zone either within the AEMP core near-field sampling zones or as separate monitoring locations, depending upon the final location of the diffusers.

3.2 EVENT MONITORING

The Event Monitoring (EM) program addresses the site specific monitoring that is required following any accidental release. A “release” may be caused by:

- spills (Meadowbank Gold Project Spill Contingency Plan; November 2013); or
- emergencies (Meadowbank Gold Project Emergency Response Plan; August 2013).

The EM program is designed to verify whether contamination of the surface soil and active zone has occurred as a result of an accidental release of a hazardous material, through monitoring of surface runoff following remediation of any release. It is anticipated that owing to the presence of permafrost beneath most of the mine footprint, there will be minimum impact to groundwater. A complete list of hazardous materials use during operations of the mine is provided in the *Meadowbank Gold Project Hazardous Materials Management Plan (October 2013)*.

The EM plan is developed on a site specific basis subsequent to a spill, and considers the type of product spilled, the potential receptors and the potential for any remaining contamination after clean up. The plan is done in coordination with the Environmental Superintendent as described in the *Meadowbank Gold Project Spill Contingency Plan (November 2013)*.

In the event of an accidental release, the water quality of the downstream receptor and possibly upstream of the receiving point, if any, is to be sampled (during the ice-free season) and analyzed. Should the spill have happened over snow cover, water and possibly soil sampling is to take place at the earliest feasible time after thaw to verify if there has been any impact to the receiving water or soil quality. The specific parameters monitored as part of the EM program will depend on the nature of the spill, and will be determined for the specific hazardous material released.

EM sampling is to occur following the clean-up of a release and the frequency of sampling will depend on the type of material spilled (wet or dry spill), the environment into which the chemical was released (surface water body or soil; frozen or thawed), and the quantity of spill material. The EM program for a particular spill will cease upon obtaining satisfactory analytical results (within 20% of background level, to accommodate for analytical accuracy) from the potentially affected areas.

3.3 ADAPTIVE MANAGEMENT PROGRAM

Results of the water quality monitoring are to be reviewed by the Meadowbank Environmental Department and chemical trends of constituents of interest are tracked for mine site monitoring and in the AEMP data (including the CREMP) to allow early detection of significant changes in water quality within the mine site prior to discharge, or if thresholds and triggers are exceeded in the receiving environment. Action plans are then to be implemented to ensure that environmental protection objectives are met.

An adaptive management program has been designed for the Meadowbank Gold Project to evaluate the monitoring data and provide a framework for action, if necessary. The program has two levels - a trigger

level to compare the monitoring data against, and an action plan of mitigative measures for identified exceedences.

The adaptive management program is divided into two sections, one for parameters with regulated discharge criteria at specific monitoring locations, as specified in the water license and by the Metal Mining Effluent Regulations (MMER). The second section is for measured parameters for which no discharge limits have been identified in the water license (i.e. CREMP monitoring).

3.3.1 Adaptive Management Program for Regulated Discharge

3.3.1.1 Action Plan

In the case of an exceedance of an NWB license limit or MMER discharge limit an action plan will be implemented. The adaptive management program requires that if one or more of the key monitored parameters exceed the respective limits, a staged sequence of responses will follow. Table 3-12 summarizes the staged adaptive action plan for the CM program for regulated discharge. Figure 3-1 is a logic diagram showing the decision path for evaluating analytical results for regulated discharge.

Should the TSS value (measured value or calculated from turbidity measurements) of non-contact water at any time during the construction, operation, or closure phases at the Portage mining area exceed regulatory guidelines, the water will be discharged to the Portage Attenuation Pond or TSF until the cause of the exceedence can be identified and the situation rectified.

In addition to the mitigative measures listed above, a number of other possible alternatives are available to reduce or treat contaminants. These mitigation measures include:

- Best management practices for sediment and erosion control would be employed to reduce TSS concentrations;
- Addition of a coagulant for the reduction of TSS in pond water;
- Use of geotextile or reamouring of banks to filter and reduce TSS in pond water;
- Deployment of absorbent booms and/or barriers within ponds to isolate surface petroleum hydrocarbon films for removal and/or treatment;
- Adjustments to on-site sewage treatment for the reduction of BOD and E. coli concentrations;
- Injection of oxygen or aeration for the reduction of ammonia;
- Addition of lime to increase a low pH value or reduce metal concentrations; and/or
- Removal of the offending source rock or the prevention of surface waters coming into contact with the offending source rock.

Table 3-12: Action Plan for Regulated Discharge

Example	Action Plan
Exceeds water license discharge criteria or MMER	- Suspension of discharge activities; - QA/QC review and analysis, and re-sample water at the particular location if necessary; - Notification of mine management (General Mine Manager and Environment Superintendent) and the Nunavut Water Board, the AANDC Water Resources water license inspector and the Kivalliq Inuit Association; - Investigation to identify possible source(s) and cause(s) of the exceedance; - Initiation of corrective actions or water treatment, and follow up monitoring; and - Resumption of discharge when concentrations are below the discharge criteria

Figure 3-1: Logic Diagram for Regulated Discharge

3.3.2 Adaptive Management Program for Non-Regulated Discharge

Aside from targeted monitoring studies (i.e. “Effects Assessment Studies”) such as those commissioned following dike construction, the CREMP is the main program aimed at measuring and assessing potential impacts of contaminants in the receiving aquatic environment that are not regulated under MMER or NWB.

This program was designed to take an integrated, ecosystem-based approach that links mitigation and monitoring of physical/chemical effects on key ecological receptors in the receiving environment. It addresses key issues identified in the Meadowbank EA (i.e., mining-related activities with the potential to affect water quality, fish habitat and fish populations). Monitoring results are intended to inform the “adaptive management” process, supporting the early identification of potential problems and development of mitigation options to address them by comparing results to established threshold and trigger levels.

3.3.2.1 CREMP Threshold and Trigger Levels

As described in the CREMP 2012 Design Document (Azimuth, 2012) trigger levels were developed to facilitate adaptive management of potential water quality issues in the receiving environment. These criteria were developed with the assumption that action will be considered before certain monitored parameters reach levels that cause or have the potential to cause adverse effects to aquatic biota. The criteria for action provide an early warning framework under which management responses may be considered, taking into account findings from other AEMP component programs. Two types of criteria were developed:

- Thresholds – license limits, regulatory guidelines or other discrete benchmarks, below which unacceptable adverse effects are not expected and above which unacceptable adverse effects may occur. If thresholds do not exist or are not used for a particular variable, then early warning triggers were developed without thresholds.
- Triggers – site specific early warning criteria that lead to action. In cases where thresholds are established, the triggers are set at values that are more conservative than the thresholds. Triggers ensure that action is taken before a threshold has been reached. For variables where no thresholds exist, the triggers are set using statistical methods based on existing data.

Thresholds were established for 22 variables based on water quality guidelines (e.g. CCME). Variables include total metals, dissolved metals, nutrients and conventional parameters. For variables with a threshold, the trigger was set as the maximum of either the value halfway between the baseline median and the threshold, or the 95th centile of the baseline data. For variables without thresholds, triggers were set equal to the 95th centile of the baseline data except in cases where less than 5% of the data exceeded the current detection limit (DL), in which case the trigger was set to two times the DL.

Water chemistry data is collected up to six months per year (April, May, July, August, September and November/December) for the annual period of paired sampling to support Before/After Control/Impact statistical analyses, recognizing that in any given year the actual number of samples collected may range from four to six depending on logistical constraints (e.g. snow and ice). Sampling is limited to open water months only for PDL (reference station) and Baker Lake stations. Two randomly located subsamples are collected at each station each month and all samples are 3 m from the surface. In addition, basic water quality data is collected at key near-field areas (i.e. TPN, TPE, SP and eventually Wally) at least once mid-winter to reduce uncertainty regarding the potential occurrence of change over winter.

Annual average concentrations (6-month mean) are compared to trigger values to determine need for action (rather than results from individual sampling events).

Further information on the development of thresholds and triggers is provided in the CREMP 2012 Design Document (Azimuth, 2012). Thresholds and triggers were also established for sediment chemistry and critical effect sizes were established for biological variables under the CREMP program.

3.3.2.2 Action Plan

A management response plan (MRP) has been developed for the AEMP (Azimuth, 2012), of which the CREMP is one component. The general MRP for the Meadowbank Mine AEMP is shown in Figure 3.2. Following the integration of the results from each independent program, the response actions are based on the cumulative results of all programs. Therefore, while we expect management actions to be taken in cases where criteria for action are exceeded, the specific actions are not linked to outcomes of the CREMP alone because the CREMP is only one of the monitoring programs under the AEMP. In other words, it is not possible or appropriate to describe the specific management actions that will be taken when CREMP triggers or thresholds are exceeded.

Nevertheless, there are two general classes of management actions – those aimed at further assessment and those aimed at mitigation. In general, exceedance of early warning triggers will trigger further assessment, which may then lead to mitigation, whereas exceedances of thresholds could possibly lead directly to mitigation. It is expected that CREMP triggers will be exceeded occasionally due to chance (given the large number of variables that are monitored, particularly for water chemistry), therefore further assessment will almost always be important.

The specific management action that would be appropriate in a given case depends on the underlying cause. For example, if a metal becomes elevated in receiving water, the identification of options for further assessment and/or mitigation options would be different if the source of the metal is groundwater versus effluent versus dust. The timing of management actions is also case-specific. In cases where further assessment is warranted, that assessment should begin as soon as practically possible. In cases where mitigation is considered, mitigation should begin as soon as the weight of evidence indicates that mitigation is warranted, and the benefits of commencing mitigation immediately outweigh the disadvantages of waiting for further information. Consultation with regulators and stakeholders is important for determining management actions (see Azimuth, 2012).

Further details on the integrated aquatic effects action plan are provided in Azimuth, 2012.

The general staged sequence of responses for triggered parameters is summarized in Figure 3.2 below.

Figure 3-2: Logic Diagram for Non-Regulated Discharge

SECTION 4. FLOW VOLUMES

Flow volumes within the mine footprint will be measured daily during periods of discharge. Flow volume measurements will be conducted using volumetric flow meters attached to each pump. For permanent pumping arrangements, these flows will be measured using permanent in-line flow meters, such as fresh and reclaim water pumping systems. For periodic batch discharges, such as secondary containment sumps, portable flow meters will be used. In seepage collection ditches flows are measured using either flow measuring weirs or using stream gauging methods.

Detailed pump records are maintained including date, pond/sump number, receiving location of pumped water, pump ID, duration of pumping, and total volume pumped. The average flow rates, total discharge per event and total cumulative discharge will be reported annually.

The monitoring locations for water flow volumes, in accordance with Part I, Section 10, and Table 2 of the water license, include:

- The volume of water obtained from Third Portage Lake (CM station ST-1);
- The volume of reclaim water obtained from the TSF for process water (ST-4);
- The volume of water for the emulsion plant (ST-3);
- The volume of water discharged from the Portage Attenuation Pond (ST-9) to Third Portage Lake diffuser and Vault Attenuation Pond (ST-10) to Wally Lake diffuser;
- The flow during periods of discharge from the sewage treatment plant, area sumps (ST-17; ST-19; ST-20; ST-23) collecting contact water, the landfarm, landfills and Waste Rock Storage Facility;
- The volume of water discharged from the marshaling area bulk fuel storage facility ; and
- The volume of effluent transferred to the pit lakes.

The pumped intervals for contact water at the Meadowbank Project site are listed in Table 4-1 below.

Table 4-1: Pumped Intervals for Surface Water at the Meadowbank Project, Mine Operation Period

Pumped from	Pumped to
Process Plant (Years 1 to 8)	TSF
Reclaim Pond (Years 1 to 8)	Process Plant
Reclaim Pond (Year 8)	Portage Pit Lake or Goose Island Pit Lake
Portage Pit sump(s) (Years 1 to 6)	Portage Attenuation Pond
Goose Island pit sump(s) (Years 2 to 5)	Portage Attenuation Pond
Vault Pit sump(s) (Years 4 to 8)	Vault Attenuation Pond
Portage Attenuation Pond (Years 1 to 6)	Third Portage Lake
Vault Attenuation Pond (Year 4 to 8)	Wally Lake

SECTION 5. REPORTING

Reporting of water quality results is to be conducted on two levels a) monthly and annually with the results of the monitoring program and per MMER requirements and b) in response to exceedences.

5.1 ANNUAL REPORTING

All water quality monitoring results are to be compiled into a brief monthly report, and sent to the Nunavut Water Board (NWB), the Aboriginal Affairs and Northern Development Canada (AANDC) Water License Inspector and to the Kivalliq Inuit Association (KIA). These reports are due within 30 days of the end of the month being reported on.

An annual report is to be submitted to the NWB, KIA, Department of Fisheries and Oceans, the Aboriginal Affairs and Northern Development Canada, Nunavut Impact Review Board, Government of Nunavut, and other interested parties by March 31st of the following year. The report is to summarize the following:

- Monitoring results for each sampling station during the year and for the life of mine (construction to end of closure); activities during the year at each station; and any exceedences at stations, the action plan applied to the exceedence, and the results of the action plan;
- Annual seep water chemistry results; including location of the samples, sources of the water collected, and results of chemical analyses of the samples;
- Annual groundwater monitoring results; activities during the year at each well site and record of well operations, well replacement, and proposed drilling for the next year; and installation details of new wells and identification of any abandoned or destroyed wells.
- Receiving water monitoring results;
- Spills and any accidental releases; event monitoring activities conducted following containment, remediation, and reclamation; and the results of EM program, any exceedence in EM results, and the action plan following the exceedence;
- Measured flow volumes;
- Effluent flow rates, volumes and calculated chemical loadings following the requirements of MMER; and
- Results of QA/QC analytical data.

5.2 EXCEEDENCE REPORTING

Any measured concentration at a CM station exceeding a regulated discharge criterion stipulated in the water license or MMER will be reported to the NWB and Environment Canada within 30 days of the receipt of the analysis. In addition, results of the action plan will be reported and, where necessary, mitigation options identified within 90 days after receipt of the analyses.

The presence of tailings process reagents or explosives in the groundwater samples will be reported within 30 days of the receipt of the analysis.

Exceedence in the concentration of a parameter in receiving water will be reported as specified in the AEMP.
