pH by Meter	E108 Saskatoon - Environmental	Water	APHA 4500-H (mod)	pH is determined by potentiometric measurement with a pH electrode, and is conducted at ambient laboratory temperature (normally 20 ± 5°C). For high accuracy test results, pH should be measured in the field within the recommended 15 minute hold time.
Chloride in Water by IC	E235.Cl Saskatoon - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Fluoride in Water by IC	E235.F Saskatoon - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrite in Water by IC	E235.NO2 Saskatoon - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate in Water by IC	E235.NO3 Saskatoon - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Sulfate in Water by IC	E235.SO4 Saskatoon - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Alkalinity Species by Titration	E290 Saskatoon - Environmental	Water	APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Ammonia by Fluorescence	E298 Calgary - Environmental	Water	J. Environ. Monit., 2005, 7, 37-42 (mod)	Ammonia in water is analyzed by flow-injection analysis with fluorescence detection after reaction with orthophthaldialdehyde (OPA).
Total Kjeldahl Nitrogen by Fluorescence (Low Level)	E318 Calgary - Environmental	Water	APHA 4500-Norg D (mod)	Total Kjeldahl Nitrogen is determined using block digestion followed by flow-injection analysis with fluorescence detection.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Total Cyanide	E333 Waterloo - Environmental	Water	ISO 14403 (mod)	Total or Strong Acid Dissociable (SAD) Cyanide is determined by Continuous Flow Analyzer (CFA) with in-line UV digestion followed by colourmetric analysis. Method Limitation: High levels of thiocyanate (SCN) may cause positive interference (up to 0.5% of SCN concentration).
WAD Cyanide	E336 Waterloo - Environmental	Water	APHA 4500-CN I (mod)	Weak Acid Dissociable (WAD) cyanide is determined by Continuous Flow Analyzer (CFA) with in-line distillation followed by colourmetric analysis.
Total Phosphorus by Colourimetry (Ultra Trace)	E372-U Calgary - Environmental	Water	APHA 4500-P E (mod).	Total Phosphorus is determined colourimetrically using a discrete analyzer after heated persulfate digestion of the sample.
Dissolved Metals in Water by CRC ICPMS	E421 Saskatoon - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Dissolved Hardness (Calculated)	EC100 Saskatoon - Environmental	Water	APHA 2340B	"Hardness (as CaCO3), dissolved" is calculated from the sum of dissolved Calcium and Magnesium concentrations, expressed in $CaCO_3$ equivalents. "Total Hardness" refers to the sum of Calcium and Magnesium Hardness. Hardness is normally or preferentially calculated from dissolved Calcium and Magnesium concentrations, because it is a property of water due to dissolved divalent cations.
Ion Balance using Dissolved Metals	EC101 Saskatoon - Environmental	Water	APHA 1030E	Cation Sum, Anion Sum, and Ion Balance are calculated based on guidance from APHA Standard Methods (1030E Checking Correctness of Analysis). Dissolved species are used where available. Minor ions are included where data is present. Ion Balance cannot be calculated accurately for waters with very low electrical conductivity (EC).
TDS in Water (Calculation)	EC103 Saskatoon - Environmental	Water	APHA 1030E (mod)	Total Dissolved Solids is calculated based on guidance from APHA Standard Methods (1030E Checking Correctness of Analysis). Dissolved species are used where available. Minor ions are included where data is present.
Nitrate and Nitrite (as N) (Calculation)	EC235.N+N Saskatoon - Environmental	Water	EPA 300.0	Nitrate and Nitrite (as N) is a calculated parameter. Nitrate and Nitrite (as N) = Nitrite (as N) + Nitrate (as N).

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Preparation for Ammonia	EP298 Calgary - Environmental	Water		Sample preparation for Preserved Nutrients Water Quality Analysis.
Digestion for TKN in water	EP318 Calgary - Environmental	Water	APHA 4500-Norg D (mod)	Samples are digested using block digestion with Copper Sulfate Digestion Reagent.
Digestion for Total Phosphorus in water	EP372 Calgary - Environmental	Water	APHA 4500-P E (mod).	Samples are heated with a persulfate digestion reagent.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Dissolved Metals Water Filtration	EP421 Saskatoon - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HNO3.

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits
- Reference Material (RM) Report; Recovery and Acceptance Limits
- Method Blank (MB) Report; Recovery and Acceptance Limits
- Laboratory Control Sample (LCS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Sara Niroomand		Inorganics, Calgary, Alberta

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Services number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percentage Difference
# = Indicates a QC result that did not meet the ALS DQO.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test specific).

Sub-Matrix: **Water**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Water**

MLA - Extensive Methodology

Samples were examined under high vacuum mode on a FEI Quanta 650 FEG Environmental SEM at Queen's University. All images are collected by a back-scatter electron (BSE) detector in 8-bit greyscale, with a colour value of 0 representing black and a value of 255 representing white. This detector is used because in BSE imaging, colour value is directly related to average atomic number. Atoms with a higher atomic number (and as such, a higher atomic weight), with an inherently larger cross-sectional area, have a higher likelihood of interacting with the electron beam generated by the SEM. This higher likelihood of interactions means more elastic collisions between the electrons and atoms in the material, with proportionally more electrons being scattered back towards the pole piece where the BSE detector is mounted. Simply, heavier materials appear brighter, and this imaging property is key to MLA analysis.

Energy dispersive spectrometry (EDS) is the core of the x-ray analysis used by MLA to identify mineral phases. X-ray spectra are collected by twin Bruker XFlash silicon drift detectors. As the electron beam interacts with a material, the energetic electrons from the beam will cause electrons within electron shells of the sample atoms to be ejected. An ejected electron represents an unstable energy level, so an electron from a higher energy level with jump to the newly created 'hole' and eject a photon representing the difference in the energy levels, specifically in the x-ray range of the light spectrum. The specific energy levels of an atom are characteristic of an element, and in combination these can be used to identify the elements a material is composed of. The EDS detector collects all x-rays generated on the sample simultaneously, and differentiates them based on the photon's energy. An x-ray spectrum is the collection of these collected x-rays represented by energy on the x-axis, and how many x-rays are detected (counts) on the y-axis. "Minerals"- that is, phases of consistent chemical composition, are thus able to be identified by their EDS spectrum.

The MLA software itself automates the operation of the SEM and facilitates the collection of these data quickly and efficiently, collecting significantly more data than would be possible by manual operation of the SEM. To begin the measurement, the operator must choose parameters appropriate to the sample to be measured. The combination of standardized brightness, resolution, beam intensity, and magnification - as well as the appropriate measurement method, of which MLA has several – all have a direct impact in the data collected. More detailed scans will take more time, so care must be taken to determine the optimal amount of time used to collect the data required to fulfill the purpose of the MLA analysis.

After the correct parameters are set, the MLA software will collect a BSE image. An image analysis algorithm will determine epoxy as background to be ignored, and then determine 'grains' based on differences in BSE colour. Depending on the MLA method, it will then direct the beam to specific areas on the grains to collect x-ray spectra associated with that x-y coordinate as determined by the software. Once completed for one frame, the MLA software will move the sample stage one frame width and repeat the process, eventually stitching all the frames together into a single large database of images and x-ray spectra with known locations.

The data collected can be quite large depending on the parameters set and commonly several gigabytes per sample are collected. MLA analysis was conducted in two modes to better characterize the sample, named SPL_Lt and XMOD_STD. The measurement type is appended on all data to clarify how the data was collected. The modes change how the x-ray beam is directed. For SPL_Lt measurements, the MLA image algorithm will find the center of each separate phase of a specified colour (as determined by the software - in this case to not analyse extraneous silicates unlikely to be As-bearing hosts for the purposes of reducing agglomeration error and measurement time), then collect an x-ray that defines that grain.

This is important to note as the Modal Mineralogy exported by the software will be biased to brighter phases, and thus not a true modal mineralogy but a measure of relative proportions of very small amounts of potential As-bearing hosts. For XMOD_STD measurements, a grid of points is collected anywhere the software has determined is not epoxy. This method does not take sample texture into account, but is less likely to have problems due image processing errors. XMOD_STD measurements are very good for determining modal mineralogy, but do not provide possibly relevant shape, mineral association, or grain size data.

It is important to bear in mind that an automated system will collect data only on the parameters set, and the data must be processed by an experienced analyst. Data processing is predominantly conducted in two pieces of software that are part of the MLA suite – Image Processing and Mineral Reference Editor. Processing MLA data begins with comparing a basic mineral reference library of characteristic mineral spectra with the collected spectra in the samples. This involves the software comparing every single spectrum (60,000 – 500,000 spectra per sample) collected on the sample with the library. The best match, to a certain percentage match, is used to give that spectrum a name. Any collected minerals that do not match in the library are labelled as Unknown.

At this point, the analyst must do several things. They must ensure that each mineral phase in the library is correctly identifying the mineral in question. For example, plagioclase can have varying ratios of sodium and calcium. If the wrong type of plagioclase is in the library, the software will not correctly identify the mineral. If a mineral is not present in the library, it must be added. The Unknown component must be critically evaluated to ensure that important minerals are not retained in this 'phase', and to make sure poor spectra are retained in this Unknown phase. Due to the automated nature of collection, a certain amount of 'mistakes' resulting in poor spectra are expected. Usually this occurs when an x-ray is collected in between two different minerals resulting in a mixed spectrum, or if a poorly polished grain is measured, which results in a poor spectrum. It is up to the analyst to determine when to believe the data is as clean as it can be, which is usually based on a combination of sample texture, grain size, mineral types, and polishing quality. For this material, a specialized library was constructed to account for as many types of As-bearing hosts as possible, based on over a decade of collected As-host spectra over a variety of projects. About 17 As-bearing phases were included in the initial library for testing, 10 of which remained in the final library. Of these 10, 5 have been confirmed to be positively identified by MLA. These were confirmed using spectrum filtering to ensure that those with minor amounts of As would still accurately identify the peak at 10.5kV, then manually checked by the analyst.

SETTINGS

High Voltage	25 kV
Beam Current	9-10nA
Spot Size	6 (to achieve a beam current of 10nA)
Working Distance	12.7mm
Imaging Standard (grey level = 255)	Native Au

Table 1: SEM Settings

	SPL_Lt	**XMOD_STD**
Number of Frames	481	481
Frame Resolution (pixels)	700	700
Scan Speed	16	16

Magnification	278	278
Image Acquisition Minimum Size (pixels)	5	5

MinLib - Fe-As-Ca oxide

Data Source: 05-SED-NPAG-ACLC-05_SPL_Lt
Mineral Groupings: Ungrouped
Mineral: Fe-As-Ca oxide
Liberation Classes: 5% classes
Data Type: Weight%
Filter: Unfiltered

APPENDIX C2: LORAX KINETIC TESTING REPORT

MEMORANDUM

To:	**Jenyfer Mosquera and Colleen Prather (Agnico Eagle Mines Ltd.)**	**Date: October 25, 2022**
From:	**Nicole Marsh and John Dockrey (Lorax Environmental Services Ltd.)**	**Project #: A667-2**
Subject:	**Meliadine Extension Tailings Kinetic Testing Results**	

1. Introduction

The Meliadine Mine is located approximately 25 kilometres (km) north of Rankin Inlet. Since Nunavut Impact Review Board (NIRB) approval in 2015, Agnico Eagle has continued to extend its knowledge of the gold deposits around the Meliadine Mine by way of additional exploration. As a result, an improved project, collectively referred to as Meliadine Extension, is being proposed. The Meliadine Extension will extend the life of the mine from 2032 to 2043 and will add underground mining activities at the already approved Wesmeg, Pump, F Zone, and Discovery deposits.

Lorax Environmental Services Ltd. (Lorax) and Okane Consultants Ltd (Okane) were retained by Agnico Eagle to complete a kinetic testing program for the Meliadine Extension in support of the NIRB application. Fourteen kinetic tests were initiated between October 2020 and January 2021, including four tailings kinetic tests to assess the acid generation and metal leaching behaviour of tailings:

- One tailings unsaturated tailings columns;
- Two saturated tailings column; and
- One paste backfill humidity cell.

The methodology and results of the unsaturated tailings column test is provided in the technical memorandum titled *Meliadine ACLC Kinetic Testing Summary* (Okane, 2022). This memorandum presents the methodology and results of the tailings saturated columns and humidity cell kinetic tests.

2. Methodology

2.1 Sample Selection

Tailings samples were collected from the Meliadine Mine TSF and the paste plant on August 18th, 2021. The whole ore tailings samples collected from the TSF were sampled from six test pits excavated by hand shovel to an approximate depth of 5 to 10 cm. Two paste samples were collected from the paste plant on August 18th, 2021. The paste was produced using a binder content of 4.5%

and was collected in two buckets where it was allowed to cure. The tailings samples were shipped to SGS Burnaby for analysis, arriving in early September. The lab reported that the paste had hardened when the buckets were unsealed. The tailings were characterized by static testing. Acid base accounting and solid phase elemental results for these samples is summarized in Table 2-2 and Table 2-3, with the full static test results for these samples reported in the *Meliadine Extension: Geochemical Characterization and Source Term Report* (Lorax 2022)

2.2 Saturated Columns

Saturated column test work was operated at the Lorax Laboratory (in Vancouver) to characterize the metal leaching characteristics of tailings materials under saturated conditions which can develop in interior sections of the TSF. Understanding how suboxic redox chemistry will affect the release and attenuation of parameters of concern in the TSF can inform the development of water quality predictions.

Two saturated columns were constructed from Plexiglass cylinders (13 cm inside diameter, 25 cm length) and filled with 6.3 kg of slurried tailings solids each (Figure 2-1). The base of the column was lined with a dispersion plate (perforated disk), a sheet of non-reactive mesh fabric, and a layer of silica sand (500 g) to allow for the even distribution of water over base area of the column before contacting tailings material. Each column was equipped with an inlet at the base of the column and an outlet port at the top of the column for sampling. The experiment was designed so that influent entered from the bottom of the column and flowed upward to minimize the risk of uncontrolled gravity-driven drainage and development of preferential flow paths (Jurjovec *et al.,* 2002; Petrunic *et al.,* 2005).

Dry tailings samples from five of the six test pits in the TSF were mixed and composited based on Table 2-1 below. Sample TSF 25 has similar composition to the other TSF samples and was retained so material would be available if additional testwork was required in the future. The composited mass was coned and quartered to collect two representative sample splits (6.5 kg dry weight each) for column construction. Each dry sample split was then mixed with approximately 1.9 L of undiluted filter press water to generate a tailings slurry. The slurries were loaded into the respective columns and the columns were sealed.

Following column construction, the two columns received either undiluted filter press water (Sat Col 1) or filter press water diluted with DI water to a ratio of 1:19 (filter press water: DI water; i.e., 5% filter press water) (Sat Col 2) as influent. Approximately 250 mL of influent was pumped into the columns on a biweekly basis, and a water quality sample of the equivalent volume was collected. Saturated column testwork was conducted at room temperature (~22°C).

Effluent was collected and analyzed for pH, conductivity, alkalinity, anions, dissolved metals, total and WAD cyanide, and nutrient parameters (nitrogen species and phosphorus). Arsenic speciation

and ferrous iron samples were collected for initial characterization of influent and porewater chemistry. Influent was collected for analysis on week 0, 8, 16 and 26 of the experiment. No influent sampling occurred after week 26 due to influent volume limitations and stabilized results for most parameters.

The saturated column experiment was run from October 15, 2020 to August 21, 2021 for a total of 45 weeks.

Table 2-1:
Saturated Column Tailings Composite Summary

Test Pit ID	Mass Available	Retain	Composite for Saturated Column Testing
	kg	kg	kg
TSF 25	5.6	5.6	0
TSF 26	7.4	0.2	7.2
TSF 27	4.9	0.2	4.7
TSF 28	4.05	0.2	3.85
TSF 29	4.15	0.2	3.95
TSF 30	4.62	0.2	4.42
Total Mass	30.72	6.6	24.12

2.3 Humidity Cell

The humidity cell test was operated at SGS Laboratories (in Burnaby) to simulate weathering of tailings paste backfill in the underground. The test is designed to mimic weathering conditions by exposing a sample to alternating cycles of dry and moist air, with regular flushing of the samples. The paste humidity cell used connate water collected from the Tiriganiaq Underground as influent for the flushing intervals.

Humidity cells are composed of Plexiglas cylinders (10.2 cm inner diameter, 25.5 cm length) filled with 1 kg of sample. The sample material is placed on a perforated acrylic disk covered in a nylon mesh. The contents of the cell are subjected to three days of dry air permeation followed by three days of humid air permeation (<10% relative humidity). On the seventh day, at the end of each wet/dry cycle, the contents of the cell are leached with 500 mL of influent (connate water). The purpose of the leaching step is to recover any readily soluble reaction products that have formed due to mineral dissolution or sulphide oxidation. The effluent is collected and analyzed for key parameters (*e.g.,* pH, conductivity, acidity, alkalinity, total and weak acid dissociable (WAD) cyanide, anions, dissolved metals and nitrogen species) at regular intervals. The humidity cell experiments were operated in a 4°C cold room to mimic the temperature of the mine underground

The paste tailings humidity cell (T1) experiment was run from February 11, 2021 to August 19, 2021.

Table 2-2:
Whole Ore Tailings Acid Base Accounting Results Summary

Parameter	Paste pH	NAG pH	Total-S	Sulphide S	Sulphate-S	SAP	Site Specific AP	Total-C	Total Inorganic-C	CaNP	CaNP-adj	Modified NP	NPR	NPR

Notes:
Sulphide-S is calculated by difference (Total-S wt.% – Sulphate-S wt.%)
SAP: Sulphide Acid Potential is calculated from Sulphide-S (by difference) content (Sulphide-S wt.% x 31.25)
Site-Specific AP is calculated from Sulphide-S multiplied by the relative composition and AP contribution of pyrrhotite, pyrite and arsenopyrite as determined from XRD, TIMA and ICP-MS results for each rock unit (described in Section 5.2.1.2).
CaNP: Carbonate Neutralization Potential is calculated from Total Inorganic Carbon content (%C wt.% x 100.09/12.01 x 10)
CaNP-adj: Adjusted Carbonate Neutralization Potential is calculated from Total Inorganic Carbon content multiplied by the relative composition and NP contribution of ankerite, calcite, dolomite and siderite as determined from XRD analysis for each rock unit (described in Section 5.2.2.3).
Modified-NP (Neutralization Potential) is determined by the Lawrence and Wang (1996) method
NPR: Net Potential Ratio is calculated by taking the ratio of CaNP-adj/SAP and Modified-NP/SAP
NAG (Net Acid Generation) pH

3. Results

3.1 Saturated Columns

Saturated column test work was completed to characterize the metal leaching characteristics of tailings materials under saturated conditions which can develop in interior sections of the TSF. Understanding how suboxic redox chemistry will affect the release and attenuation of parameters of concern in the TSF can inform the development of water quality predictions. Complete analytical results for saturated column effluent are reported in Appendix A.

Both saturated column tests produced circumneutral to alkaline pH values for the duration of the experiment. Minimum values were observed in the initial weeks of testing (pH 6.76 and 6.42) before stabilizing at more alkaline values after week 8 (pH 7.42 to 8.07). Conductivity in the columns show a trend of an initial increase in the first few weeks followed by a gradual decline and stabilization. Conductivity in Sat Col 1 peaked at 86,300 µS/cm in week 4 and stabilized to concentrations comparable to the undiluted filter press influent by week 32 (~2,600 µS/cm). Similarly, maximum conductivity in Sat Col 2 (72,100) was observed in week 4 and stabilizing in the final few weeks of the experiment (~4,200 to 4,500).

Effluent results were compared to the MDMER and AEMP guidelines to identify parameters which may be elevated in paste backfill runoff, however, these guidelines are only used as a screening tool as water from the underground will not be directly discharged to the receiving environment.

Effluent results were compared to the Metal and Diamond Mining Effluent Regulations (MDMER) and Aquatic Effects Monitoring Program (AEMP) Water Quality Guidelines (Table 3-1). Note that these guidelines are only used as a screening tool as water from the underground will not be directly discharged to the receiving environment. Guidelines which were derived for total concentrations are applied to dissolved concentrations for the purpose of this assessment. Saturated column effluent results generally reported concentrations above guideline in one or more effluent samples over the course of the experiment, with the exception of Ba, Mn, Tl and V, which were routinely below guideline values. Analytical results for Cd, Hg and Zn were typically below detection, however, detection limits were often above AEMP criteria. High detection limits and decreased analytical precision are an artifact of high TDS in effluent samples.

Parameters which have significantly higher concentrations than AEMP guidelines (>5x) in saturated column effluent included TDS, NH_3, NO_2, NO_3, SO_4, Cl, Ag, As, Co, Cu, Fe, Mo, Pb and Se (Figure 3-1 through Figure 3-4). Parameters in column leachate above MDMER guidelines included As, T-CN, NH_3 and Cu. Each of these parameters were also above their respective guidelines in the filter press water used to initiate the columns.

In general concentrations of most parameters declined over time as the initial filter press water was rinsed out of the column and/or reactive parameters decayed (*i.e.*, T-CN and NH_3). Notably, concentrations of T-CN, Ag, As and Cu declined below influent concentrations over the course of the experiment indicating that attenuation of these parameters was occurring within the saturated columns. These attenuation reactions were likely related to decay of T-CN and sorption of Ag, As and Cu to mineral surfaces.

Parameters which were elevated in column effluent relative to filter press water included TDS, SO_4, NO_2, Co, Se and Mo. Elevated TDS and SO_4 are likely related to dissolution of minerals formed within the mill (gypsum) or as evaporites on the TSF surface (halite and gypsum). Note that both halite and gypsum were identified in XRD results from several of the TSF samples (Lorax, 2022). Nitrite forms as an intermediate reaction product during NO_3 reduction. Formation of NO_2 was likely a result of incomplete reduction of NO_3 to NH_4 or N_2 gas within the columns.

The trace metals Co, Se and Mo occur in concentrations greater filter press water, but otherwise show similar rinsing behaviour as other parameters. The concentration of these parameters rapidly declines over time, stabilizing at concentrations similar to column influent after 24 to 28 weeks. The elevated initial concentrations of these metals indicate they are present as a water-soluble phase (*e.g.,* evaporates or oxides) which is quickly depleted within the column.

Table 3-1:
Summary of Metal and Diamond Mining Effluent Regulations (MDMER) and Aquatic Effects Monitoring Program (AEMP) Water Quality Guidelines

Parameter	Unit	MDMER	AEMP
TDS	mg/L		1000
NH_3-N	mg/L	37	2.68
NO_3-N	mg/L		2.93

T-V	mg/L		0.12
D-Zn	mg/L		0.0051

Notes:
AEMP benchmark for metals apply to the total fraction. In the case of Pb, Mn, Sr, and Zn, the freshwater aquatic life guidelines derived for the dissolved fraction have been adopted as the AEMP benchmark.
AEMP benchmarks for total Cd, Cu and Ni and dissolved Zn are derived from long-term Canadian Council of Ministers of the Environment (CCME, 2007) Freshwater Quality Guidelines for Protection of Aquatic Life. Guidelines for these parameters are hardness dependent and were calculated using median concentrations from monitoring data collected in 1997 to 2020 from Meliadine Lake monitoring stations (hardness = 20 mg $CaCO_3$/L; pH = 7.5; DOC = 2 mg/L).
The sulphate guideline is hardness dependent- 128 mg/L corresponds to a median hardness < 30 mg $CaCO_3$/L in Meliadine Lake.
The ammonia AEMP benchmark is derived from CCME guidelines and assumes a temperature of 10°C and pH 7.5 (median value in Meliadine Lake).

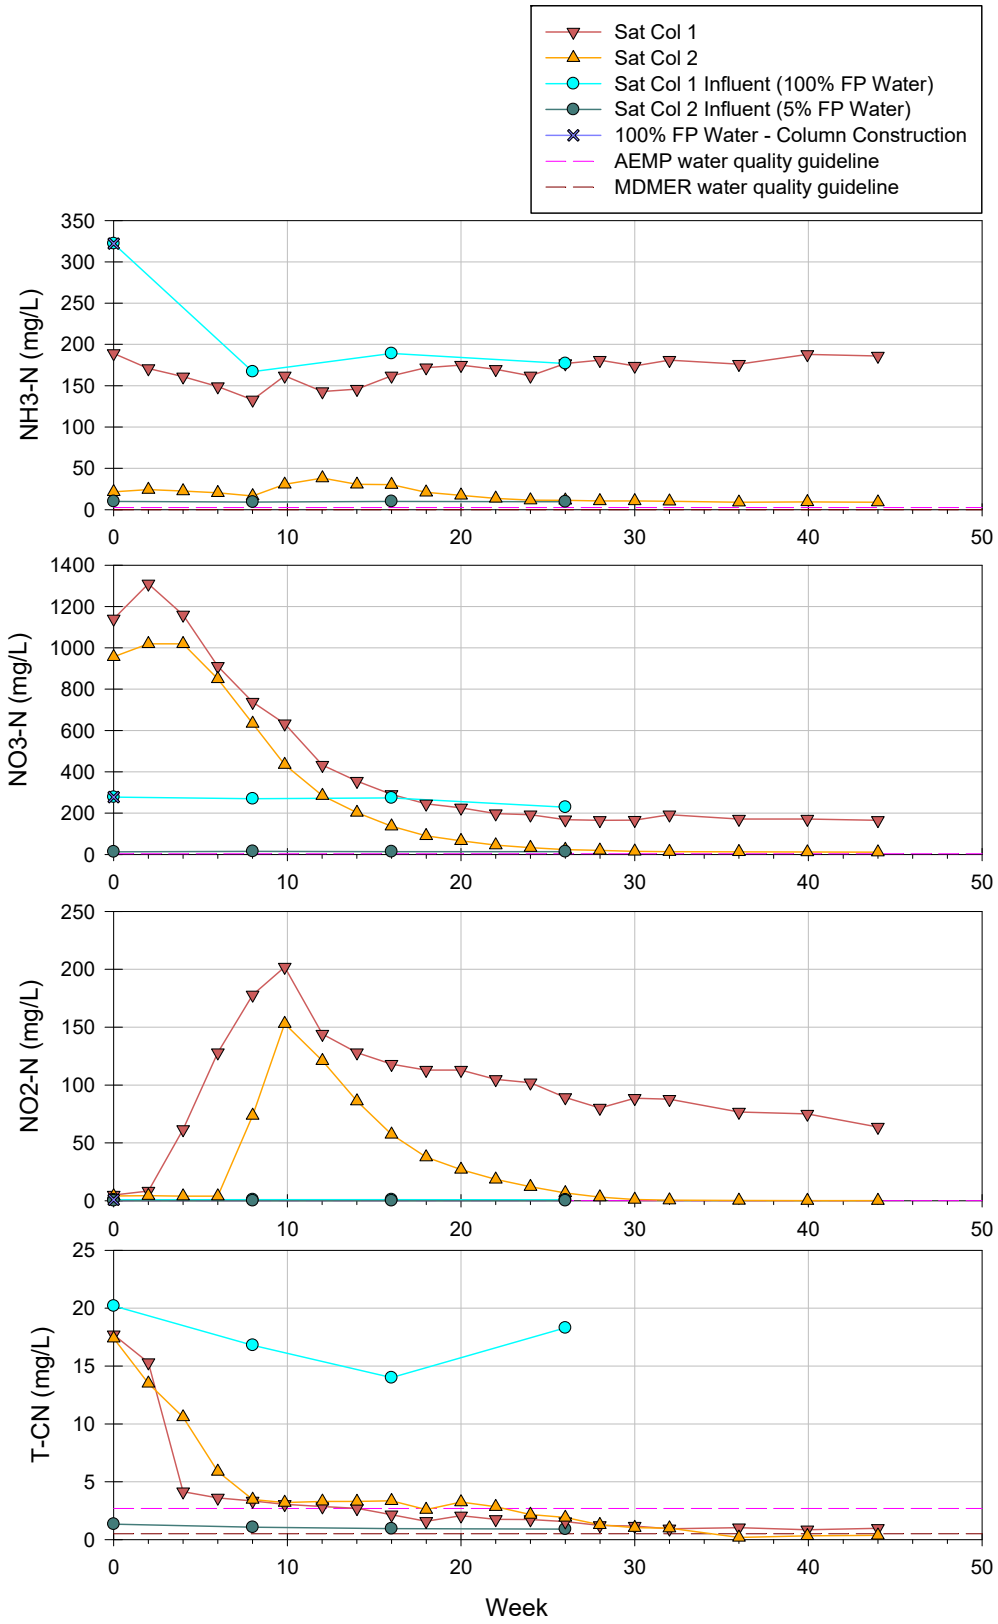

Figure 3-2: Timeseries plots of saturated column results for ammonia, nitrate, nitrite and total cyanide.

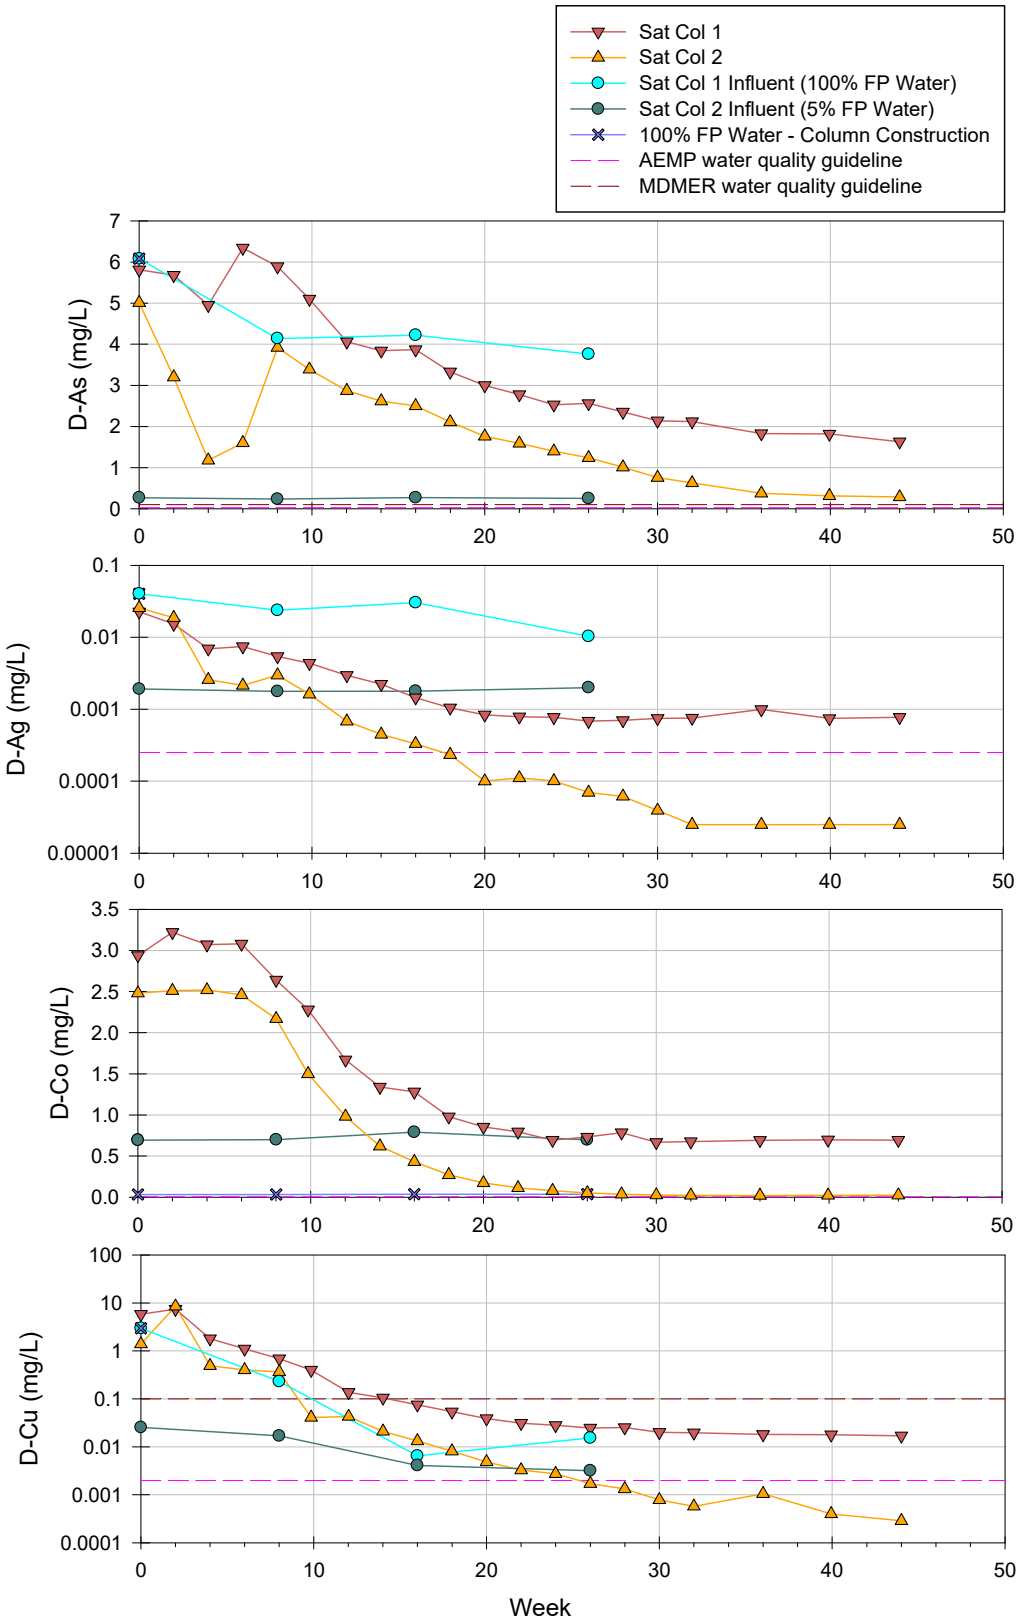

Figure 3-3: Timeseries plots of saturated column results for dissolved arsenic, silver, cobalt and copper.

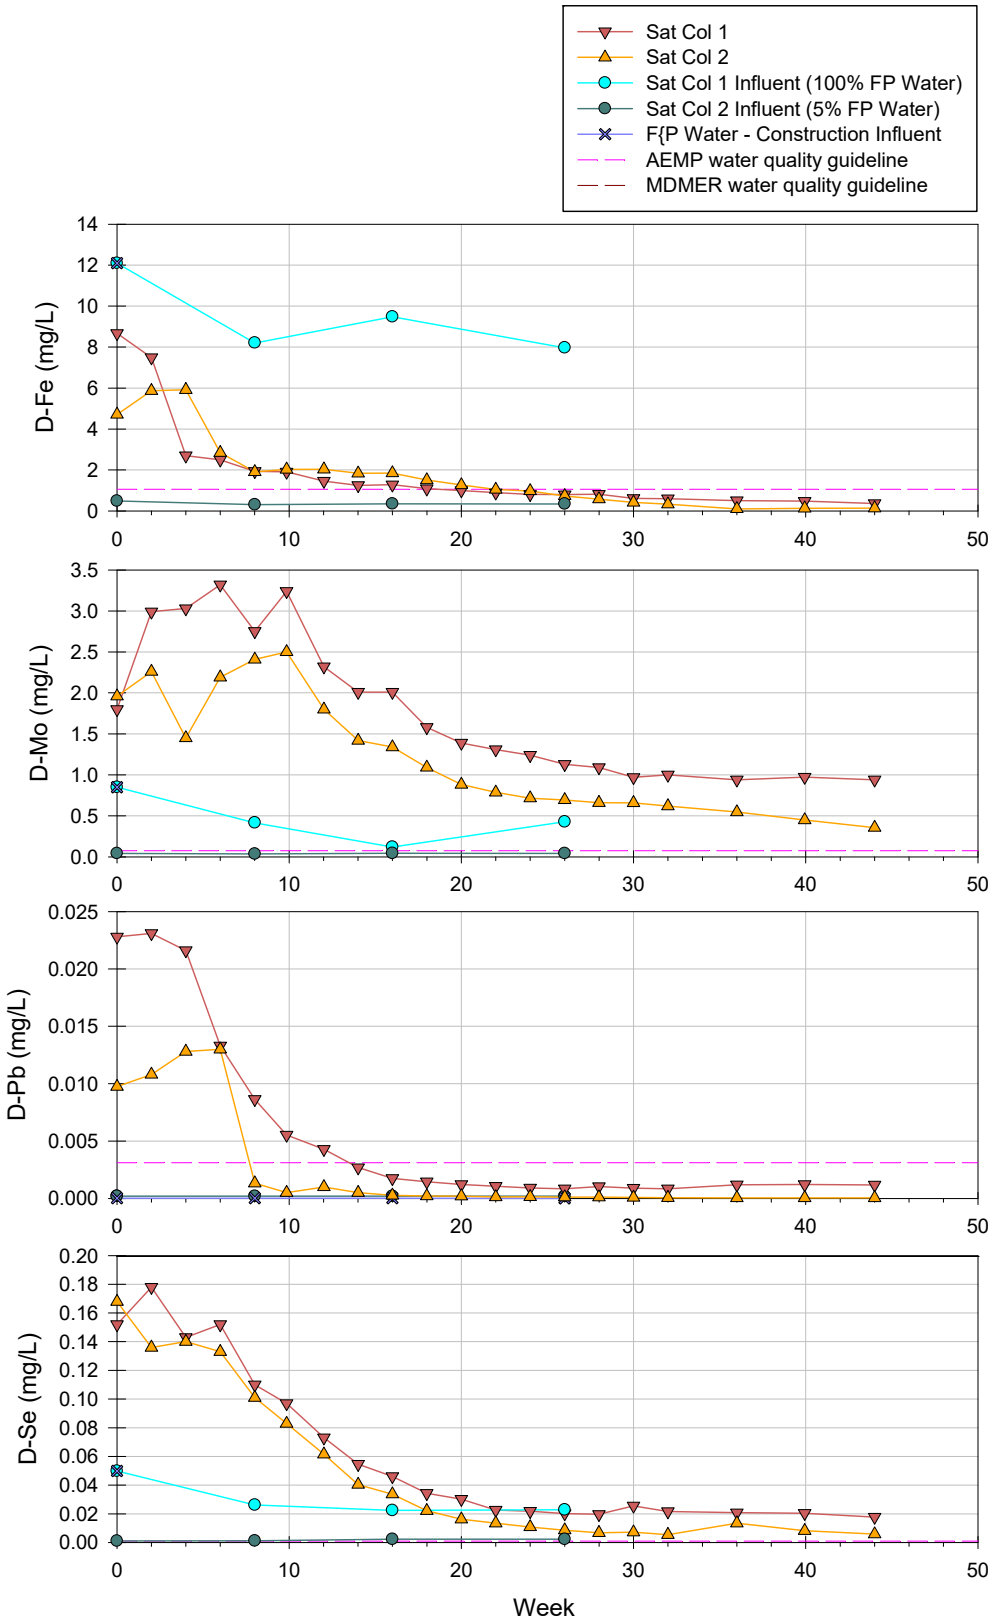

Figure 3-4: Timeseries plots of saturated column results for dissolved iron, molybdenum, lead, and selenium.

3.2 Humidity Cell

Tailings generated by the Meliadine Extension operations will be deposited as dry stack tailings placed in the TSF or paste backfilled placed in the underground. The purpose of paste humidity cell test was to provide information on metal leaching potential of tailings backfill in the mine underground. Connate water influent and HCT effluent results are presented in Appendix B. Timeseries plots of select parameters are presented in Figure 3-5 to Figure 3-8.

The paste tailings HCT showed elevated pH in the first two cycles of the test (pH 9.5 to 8.5) before stabilizing at lower, but still circumneutral to alkaline, pH values for the remainder of the test (pH 7.21 to 8.25) (Figure 3-5). The rapid decline in pH reflects rinsing of residual cement binder from the paste tailings sample followed by carbonate mineral buffering.

Effluent results were compared to the MDMER and AEMP guidelines to identify parameters which may be elevated in paste backfill runoff, however, these guidelines are only used as a screening tool as water from the underground will not be directly discharged to the receiving environment.

Connate water influent and HCT effluent reported detectable concentrations above AEMP guidelines for TDS, NH_3, Cl, As, Cd, Cr, Co, Cu, Mo, P, Se, Ag, Sr and Zn. Fluoride concentrations were also above the AEMP guideline in the HCT effluent, and above the Mn guideline in the connate influent. Analytical results for NO_2, and dissolved Hg were routinely below detection, however, detection limits were often above AEMP criteria. High detection limits and decreased analytical precision are due to the high TDS in the connate influent and HCT effluent.

Especially high detection limits were reported during the July 21, 2021 sampling event. The timeseries plots appear to show an increase in dissolved Cr, Cu, Fe, Zn for this sample event, however the sudden increase is due to elevated detection limits and should not be interpreted as an increasing trend. Reduced analytical precision and variable detection limits is an artifact of the high TDS of HCT effluent.

Parameters which were significantly higher concentrations than AEMP guidelines (>5x) in HCT effluent included TDS, NH_3, SO_4, Cl, Ag, As, Cd, Co, Cu, Se, and Zn (Figure 3-6 through Figure 3-8). Parameters above MDMER guidelines were limited to As, T-CN. Of these parameters TDS, SO_4, NH_3, Cl, Ag, Cd and Zn were also above the respective guidelines in column influent.

Major ions and TDS were generally stable for the duration of the experiment with column effluent showing similar concentrations as column influent. Results for SO_4 and Ca were notable in that effluent concentrations varied overtime and showed elevated concentrations compared to influent. Release of these parameters from the paste tailings samples is likely related to gypsum

dissolution and/or oxidation of sulphide minerals. Gypsum was not identified in XRD analysis of paste tailings, but likely formed in low quantities (<1 wt.%) as a result of lime addition.

Most trace metals either declined in concentration or were stable for the kinetic test duration with the notable exception of As (Figure 3-7). Initial arsenic concentrations of 1.0 mg/L increased to over 3.0 mg/L in the first 9 cycles, and then fluctuated between 1.2 and 3.0 mg/L for the remainder of the experiment. The release of As and other trace metals from the HCT is likely related to a combination of sulphide mineral oxidation and ion exchange driven by interaction with connate water. Elevated Cr in HCT effluent is likely related to the presence of hexavalent Cr in the cement binder used in paste tailings production. However, Cr results are highly variable, fluctuating between 0.02 mg/L and the method detection limit of 0.008 mg/L. This may in part be related to poor analytical precision in the high TDS effluent.

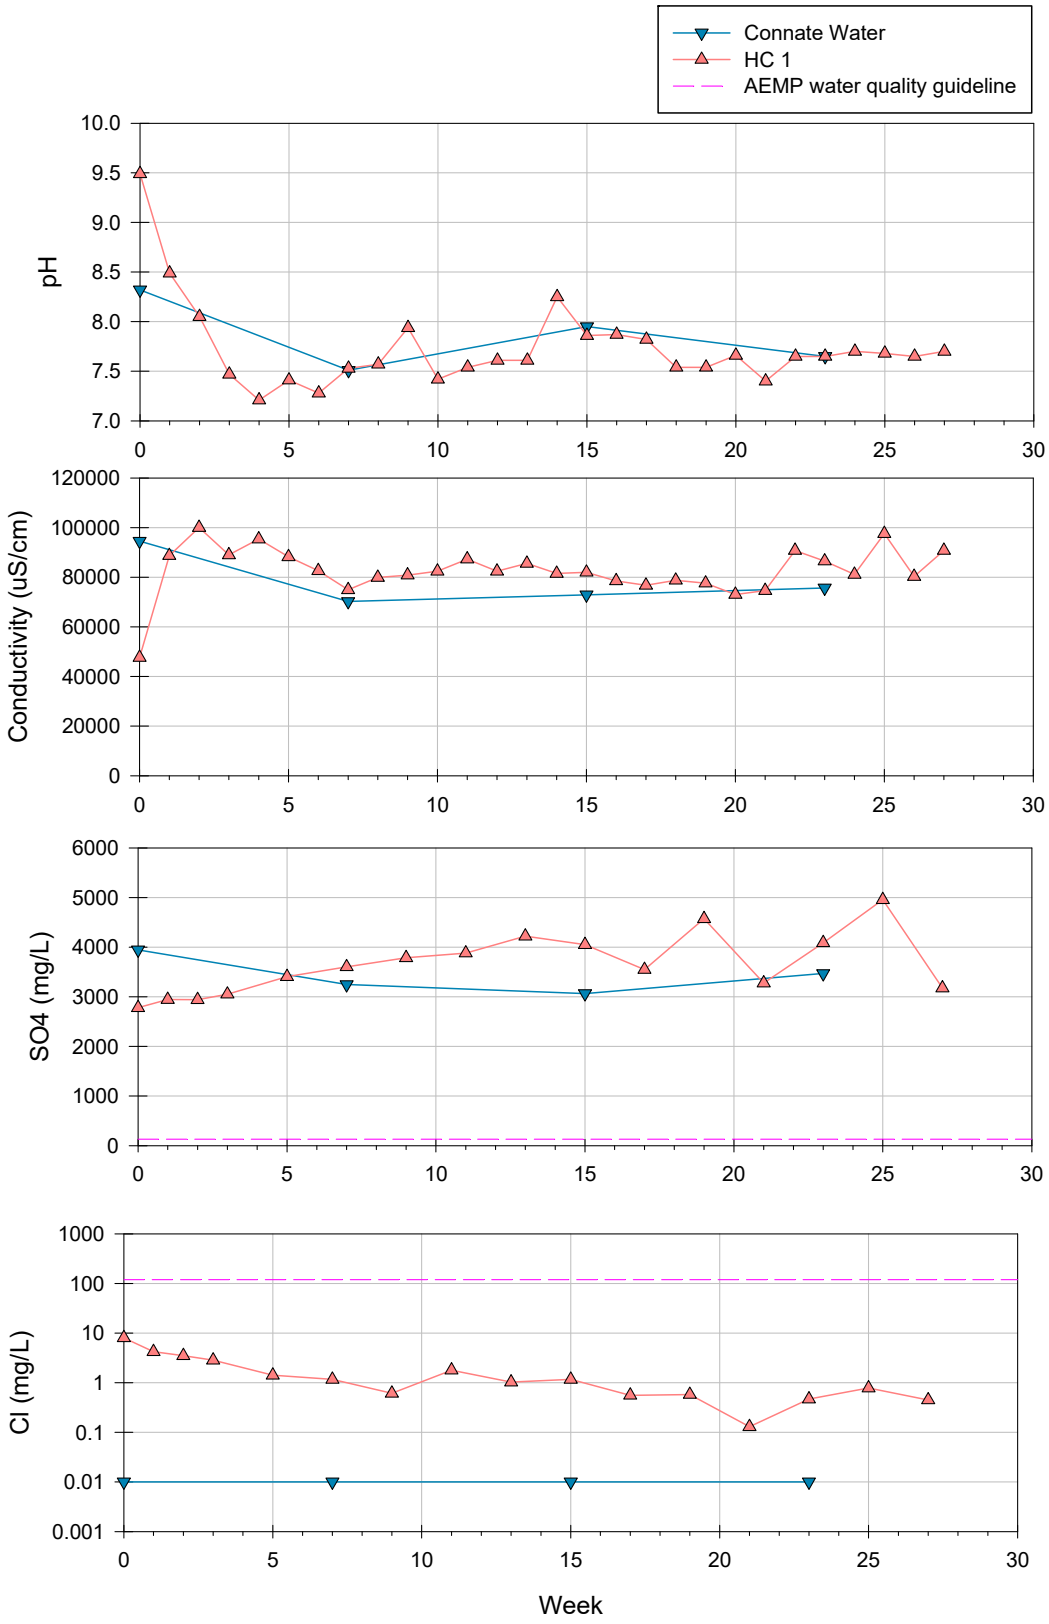

Figure 3-5: Timeseries plots of humidity cell results for pH, conductivity, sulphate and chloride

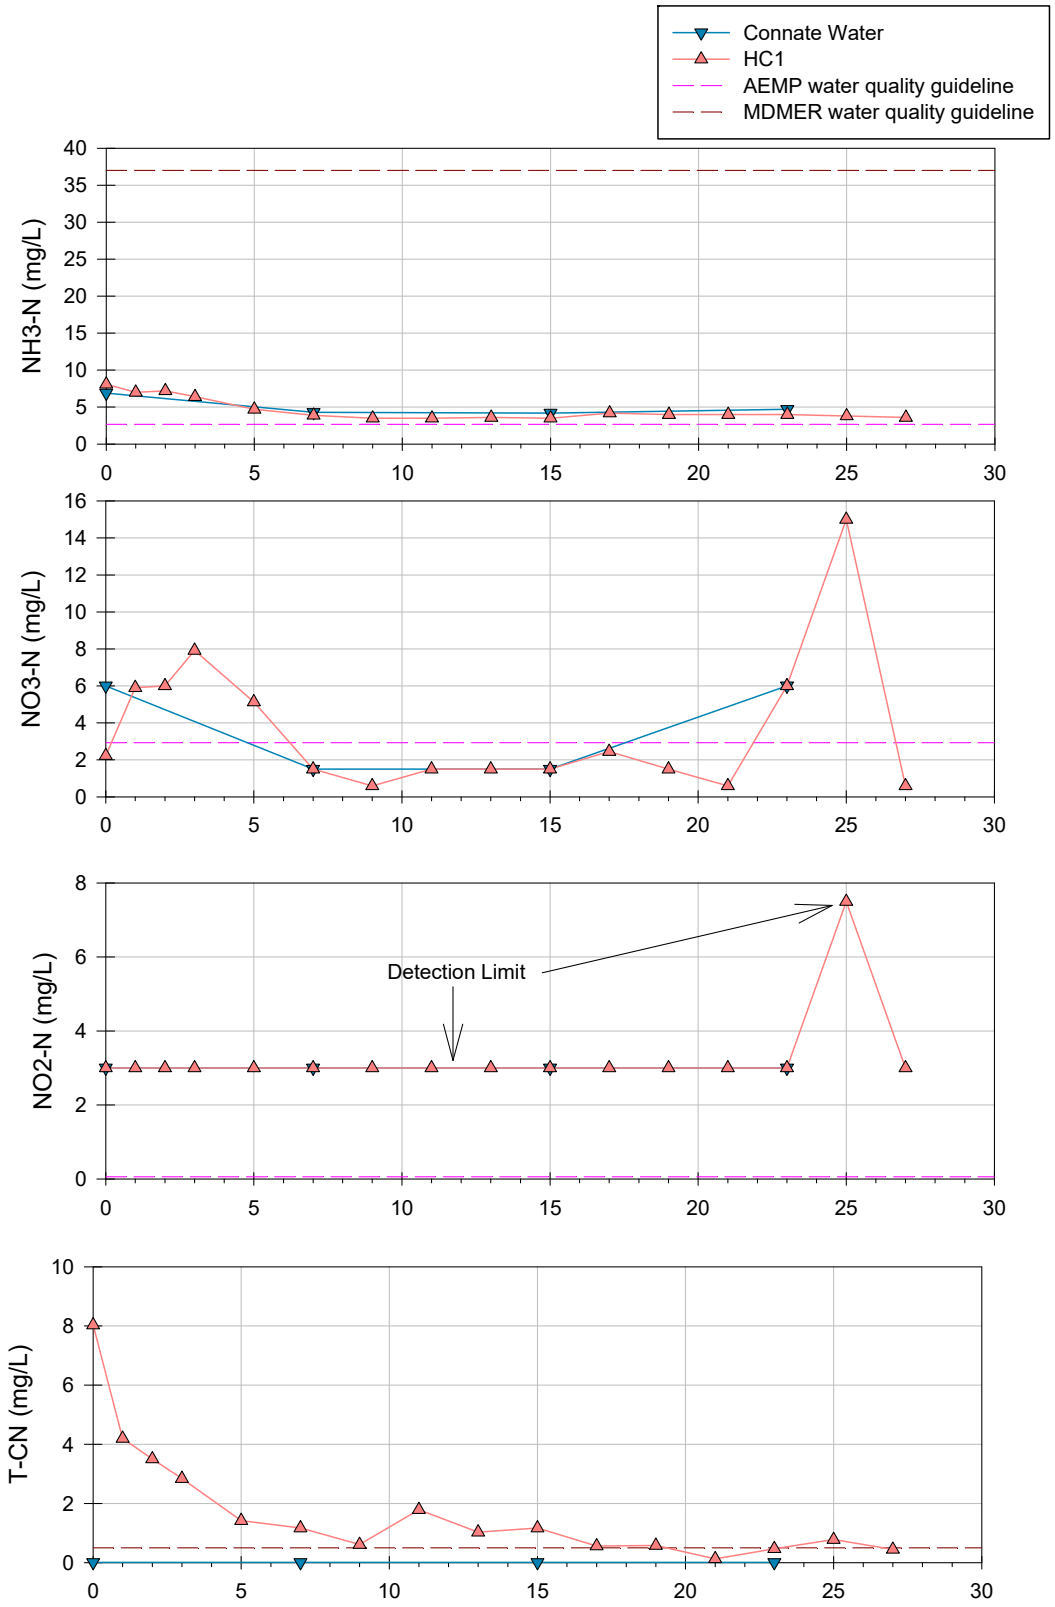

Figure 3-6: Timeseries plots of humidity cell results for ammonia, nitrate, nitrite, and total cyanide.

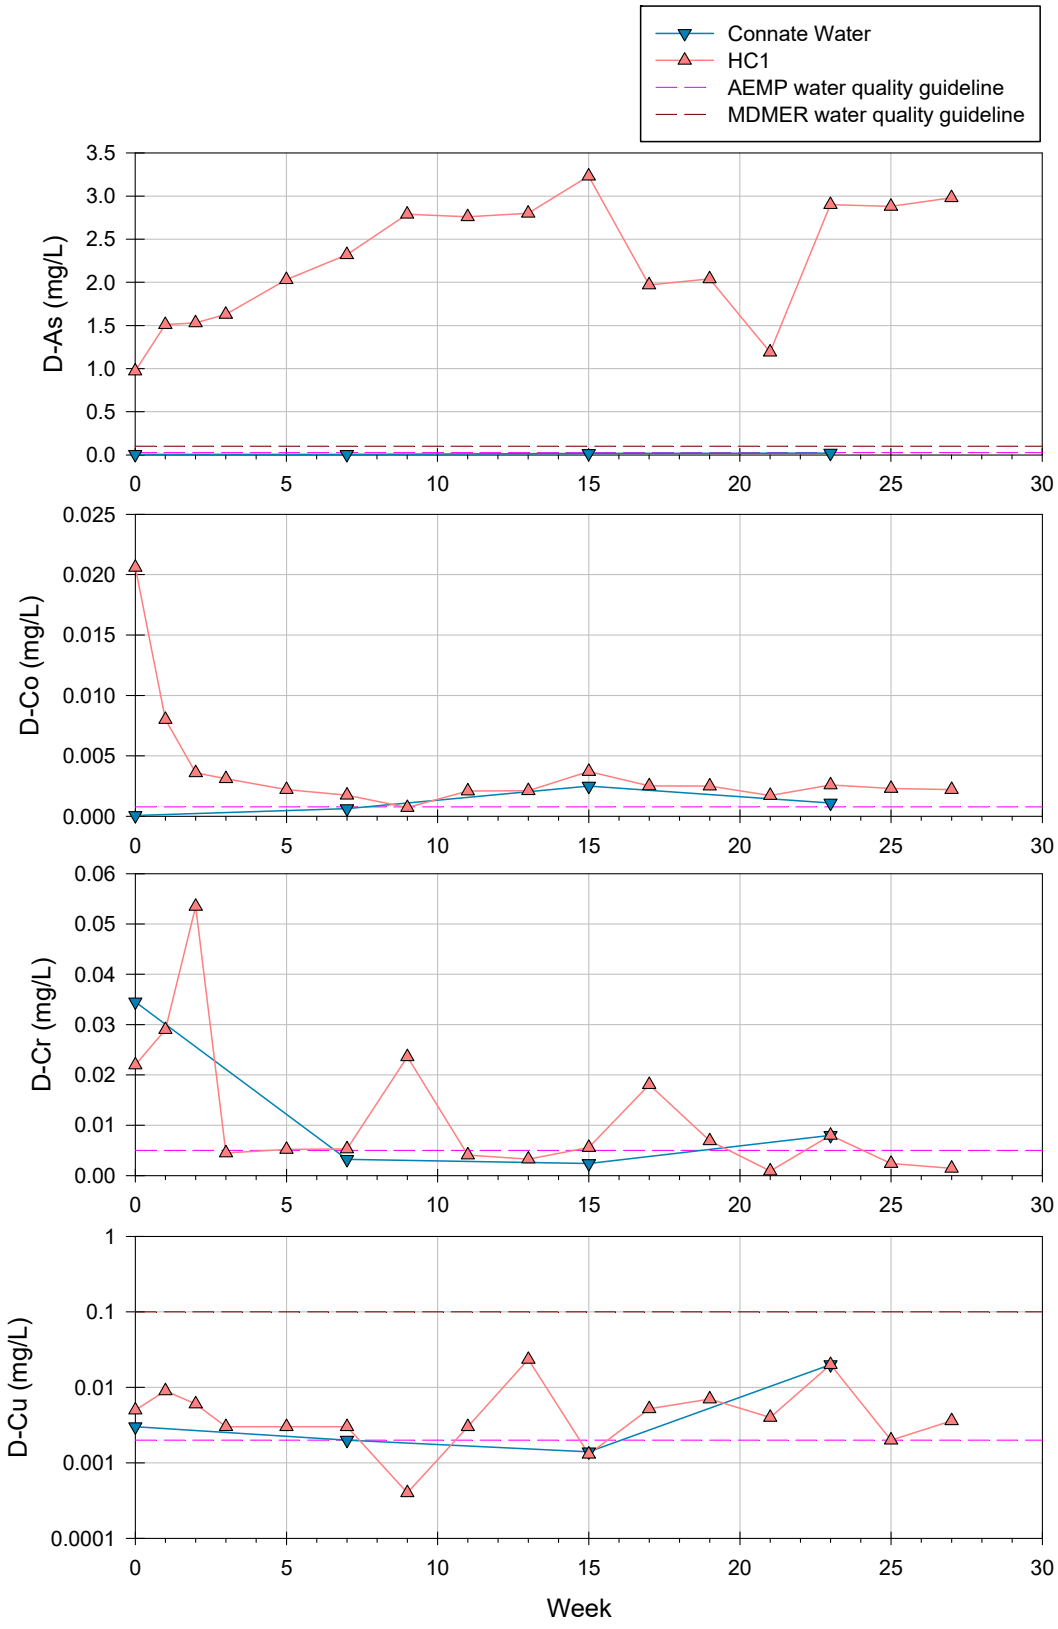

Figure 3-7: Timeseries plots of humidity cell results for dissolved arsenic, dissolved cobalt, dissolved chromium and dissolved copper.

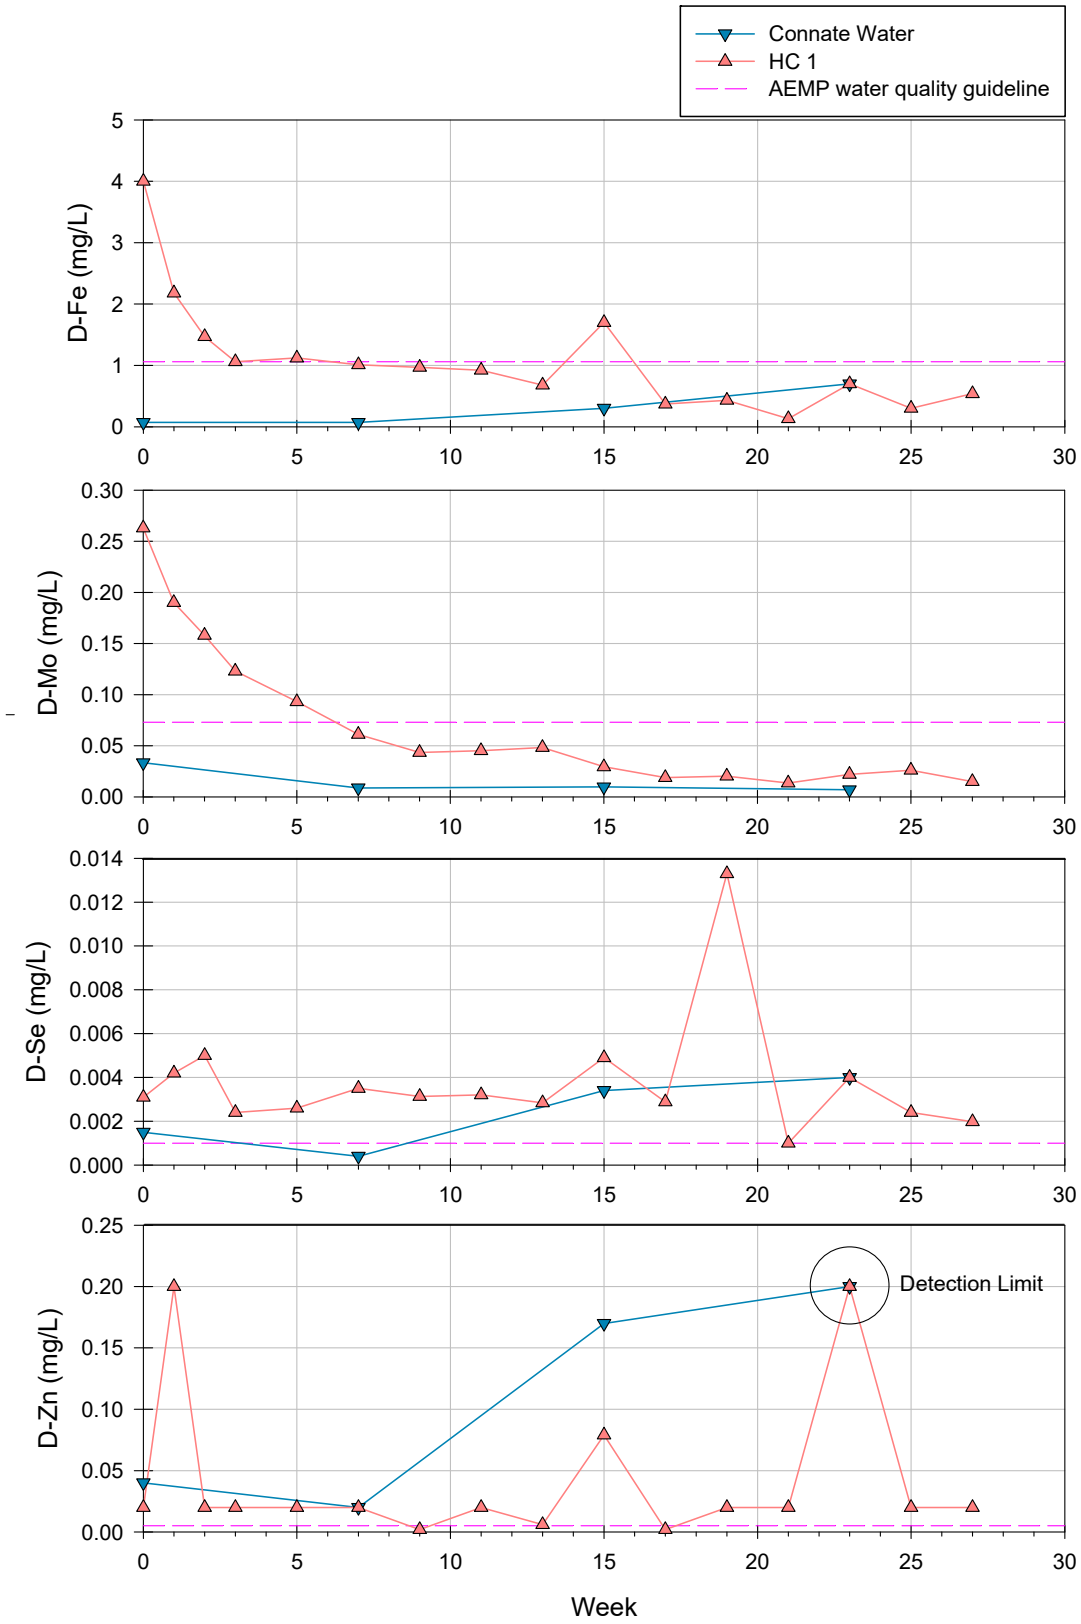

Figure 3-8: Timeseries plots of humidity cell results for dissolved iron, molybdenum, selenium and zinc.

4. Conclusions

4.1 Saturated Columns

Saturated column test work was completed to characterize the metal leaching characteristics of tailings materials under saturated conditions which can develop in interior sections of the TSF. Two saturated columns with undiluted filter press water influent and diluted (5%) filter press influent aimed to simulate initial and flushed conditions in the saturated portions of the TSF, respectively.

Both saturated columns produced circumneutral to alkaline pH values (pH 6.76 to 8.07) for the duration of the experiment. Major ions and dissolved metals generally declined over the course of the experiment as the initial filter press water was rinsed out of the column an/or reactive parameters decayed (i.e., T-CN and NH_3). Notably, concentrations of T-CN, Ag, As and Cu declined below influent concentrations over the course of the experiment indicating that attenuation of these parameters was occurring within the saturated columns. These attenuation reactions were likely related to decay of T-CN and sorption to mineral surfaces.

Overall, saturated column results show that metal release will be dominated by rinsing of filter press water and water-soluble oxides and evaporites. Saturated column results show limited evidence for reductive dissolution reactions. This is likely related to the large reservoir of NO_3 present in filter press water, preventing the development of conditions capable of reducing Mn and Fe oxide minerals.

4.2 Humidity Cell

The humidity cell test was completed to simulate weathering of tailings paste backfill in the underground and evaluate the metal leaching potential of the tailings paste backfill. The HCT used connate water collected from the Tiriganiaq Underground for the flushing intervals for the experiment.

The paste tailings HCT showed elevated pH in the first two cycles of the test (pH 9.5 to 8.5) before stabilizing at lower, but still alkaline, pH values for the remainder of the test (pH 7.21 to 8.25) due to buffering from residual cement binder.

Major ions and TDS were generally stable for the duration of the experiment with column effluent showing similar concentrations as column influent. Most trace metals either declined in concentration or were stable for the kinetic test duration, with the notable exception of As which fluctuated between 1.2 and 3.0 mg/L for the experiment. The release of As and other trace metals from the HCT is likely related to a combination of sulphide mineral oxidation and ion exchange driven by interaction with connate water.

Overall, the results of the paste backfill HCT show that oxidation of paste tailings in the mine underground has the potential to release a number of parameters, most notably As and Cr. The ability of paste to leach metals is expected to decline over time as the paste cures and backfilling progresses, limiting oxygen ingress into the backfilled stopes.

5. Closure

We trust that this memo meets your expectations. Please contact the undersigned with any questions or comments.

Respectfully,

Notes:
Arsenic speciation testing completed on select samples include the following inorganic and organic species: arsenite (As-III), arsenite (As-V), arsenobetaine (AsB-As), dimethylarsinic acid (DMA-As), and monomethylarsonic acid (MMA-As).
Grey shading - values greater than the Aquatic Effects Monitoring Program (AEMP) water quality guidelines
Bolded - values 5x greater than the AEMP water quality guidelines
Red - values greater than the Metal and Diamond Mining Effluent Regulations (MDMER) water quality guuideline

Notes:
Arsenic speciation testing completed on select samples include the following inorganic and organic species: arsenite (As-III), arsenite (As-V), arsenobetaine (AsB-As), dimethylarsinic acid (DMA-As), and monomethylarsonic acid (MMA-As).
Grey shading - values greater than the Aquatic Effects Monitoring Program (AEMP) water quality guidelines
Bolded - values 5x greater than the AEMP water quality guidelines
Red - values greater than the Metal and Diamond Mining Effluent Regulations (MDMER) water quality guuideline

Notes:

Arsenic speciation testing completed on select samples include the following inorganic and organic species: arsenite (As-III), arsenite (As-V), arsenobetaine (AsB-As), dimethylarsinic acid (DMA-As), and monomethylarsonic acid (MMA-As).

Grey shading - values greater than the Aquatic Effects Monitoring Program (AEMP) water quality guidelines

Bolded - values 5x greater than the AEMP water quality guidelines

Red - values greater than the Metal and Diamond Mining Effluent Regulations (MDMER) water quality guuideline

APPENDIX C3: SOURCE TERM UPDATE WITH WQM VALIDATION

TECHNICAL MEMORANDUM

To:	**Jenyfer Mosquera and Colleen Prather (Agnico Eagle Mines Ltd.)**	**Date: January 13, 2023**
From:	**John Dockrey (Lorax Environmental Services Ltd.)**	**Project #: A667-2**
Subject:	**Meliadine Extension Source Term Update for Water Balance and Water Quality Model**	

1. Introduction

Agnico Eagle Mines Limited (Agnico Eagle) operates the Meliadine Mine, located 25 km north of Rankin Inlet in the Kivalliq region of Nunavut. The Project Certificate issued in 2015 included approval of a multi-phase approach to development, including mining of the Tiriganiaq deposit using open pit and underground mining methods and mining of the Pump, F Zone, Discovery and Wesmeg deposits using open pit methods. Meliadine Extension proposes to extend the life of the mine from 2032 to 2043 and the addition of underground mining activities at the already approved Wesmeg, Pump, F Zone, and Discovery deposits. Meliadine Extension includes the development of six gold deposits located within the previously approved footprint (F Zone, Pump, Wesmeg, Wesmeg North, Tiriganiaq-Wolf and Discovery) and associated infrastructure.

Lorax Environmental Services Ltd. (Lorax) was retained by Agnico Eagle to update the site-wide water balance and water quality model (WBWQM) and associated source terms to represent the annual progression of the Meliadine Extension mine layout, in support of the Water Licence Amendment process with the Nunavut Water Board. This model iteration builds upon the WBWQM developed for the 2022 FEIS application (Base Case) using the GoldSim modelling platform (Lorax, 2022a and 2022b), with certain modifications to incorporate additional information and refinements to the mine plan. The WBWQM updates are described in Lorax (2023).

The purpose of this memo is to describe source term updates incorporated into the Lorax (2023) WBWQM iteration. The source term approach and updates are described in Section 2 and 3, respectively. The source terms are validated against site water quality monitoring data in Section 4. Finally, Section 5 provides a summary of the source term inputs used in the Lorax (2023) WBWQM.

2. Approach and Information Sources

Geochemical source terms predict drainage chemistry from mine facilities and disturbed areas associated with mining operations. Individual source terms are developed for: seven open pit WRSFs, four saline WRSFs, seven ore stockpiles, seven underground mines, pit wall rock

exposures from 18 mine pits, the TSF, disturbed areas and mine facility areas. Source terms are developed on an annual time step and are entered into the water quality model as concentrations.

The source terms developed for the 2022 FEIS Application described in the *Geochemical Characterization and Source Term Report* (Lorax, 2022b) are updated to reflect changes to the mine plan and incorporate additional information where available. In general, these updates are driven by changes in the water balance, mine facility layout, and additional kinetic testing data which are documented in the following reports:

- Water balance update for Generic WRSFs and Discovery WRSF (OKC, 2022a)
- Thermal modelling update for Discovery WRSF (OKC, 2022b)
- Discovery open pit additional WRSF (Tetra Tech, 2023)
- Groundwater dewatering rate and TDS modified from (Golder, 2022)
- Kinetic testing program final results (OKC, 2022c; Lorax, 2022c)

These updates do not change the overall source term approach described in Lorax, (2022b), which rely in large part on calibration of source term predictions to site monitoring data.

3. Source Term Updates

In this section updates to source terms originally developed for the 2022 FEIS Addendum in Lorax (2022a) are described.

The WRSF source terms were updated to incorporate thermal and water balance modelling completed after the 2022 FEIS Addendum submission (OKC, 2022a; 2022b). These updates have implications for the post-closure WRSF source terms, when RCP4.5 climate forcings lead to climatic deviations from the historic record. These updates do not impact Operations WRSF source terms which are calibrated to site monitoring data. The WRSF source term calculations were updated as follows:

- Water balance modelling shows that contact water (interflow + runoff) will increase from 59 mm at the end of mine life (2043) to 84 mm at the end of the modelling period (2120) for generic WRSFs, and from 52 mm to 97 mm for the Discovery WRSF. This results in an 41% increase in contact water from the generic WRSF, and an 88% increase in contact water from the Discovery WRSF.
- Thermal modelling results for Discovery WRSF show that the active zone thickness will remain within the 6 m thermal cover constructed with NPAG mine rock for the duration of the model period. For instance, the annual duration that the active zone is not frozen will increase from 4.7 months to 5.1 months on average. This will be accompanied by an increase in the average temperature from 6.6ºC to 7.5ºC during summer months within the

active zone. Overall, the geochemical loads from waste rock in the active zone are expected to increase by 36% over the model period as a result of changes in the Discovery WRSF thermal profile. Note that this is similar to generic WRSFs where geochemical loads are expected to increase by 27% in post-closure, which was incorporated into Lorax (2022b) source terms and is not updated herein.

- The combined influence of increasing precipitation and increasing temperature generated in the RCP4.5 climate scenario will result in WRSF source term concentrations decreasing by 0.13% and 0.36% per year for Discovery WRSF and Generic WRSFs, respectively. The decline in concentrations is a result of WRSF contact water volume outpacing the increases in geochemical loading rates driven by a warming thermal profile.

Underground mine source terms were modified to incorporate the hydrogeology results presented in Golder (2022). This resulted in the following updates:

- Salinity of underground mine waters were updated which impacts TDS as well as parameters calculated using a correlation to TDS observed in Tiriganiaq Underground monitoring data. These parameters included SO_4, Ca, Mg, K, Na, Ba, ^{226}Ra and Cl.
- Loading based source terms for As, Se, Mo, NO_3, NO_2 and NH_3 were updated to incorporate changes in groundwater flow rates.

The WRSF and TSF source terms in Lorax (2022b) incorporated interim results from the Meliadine Extension kinetic testing program. These inputs were updated with final kinetic testing program results as follows:

- The closure TSF infiltration source term relies on TSF column results. This source term was updated to incorporate the final TSF column results which were ran for 52 cycles.
- The solubility constraint for Co was set to the 90th percentile column results for GB and VO rock types. This calculation only incorporated the first 17 cycles of column data in Lorax (2022b). Incorporating the entire dataset (38 cycles) results in the solubility cap changing from 0.0009 to 0.0008 for GB, and 0.00043 to 0.0003 mg/L for VO.

No updates beyond what is explicitly outlined herein have been made the 2022 FEIS Application source terms (Lorax, 2022b).

4. Validation of Predicted Water Quality

In this section, source terms are validated against site monitoring data from 2019 to 2022 to confirm that source terms can conservatively reproduce observed operational water quality. This exercise uses the WBWQM developed for the 2021 Annual Report (Agnico Eagle, 2022) which incorporates the current site layout with discretized catchment areas (Figure 4-1, Figure 4-2 and Figure 4-3), site pumping records, and the Lorax (2022b) source terms.

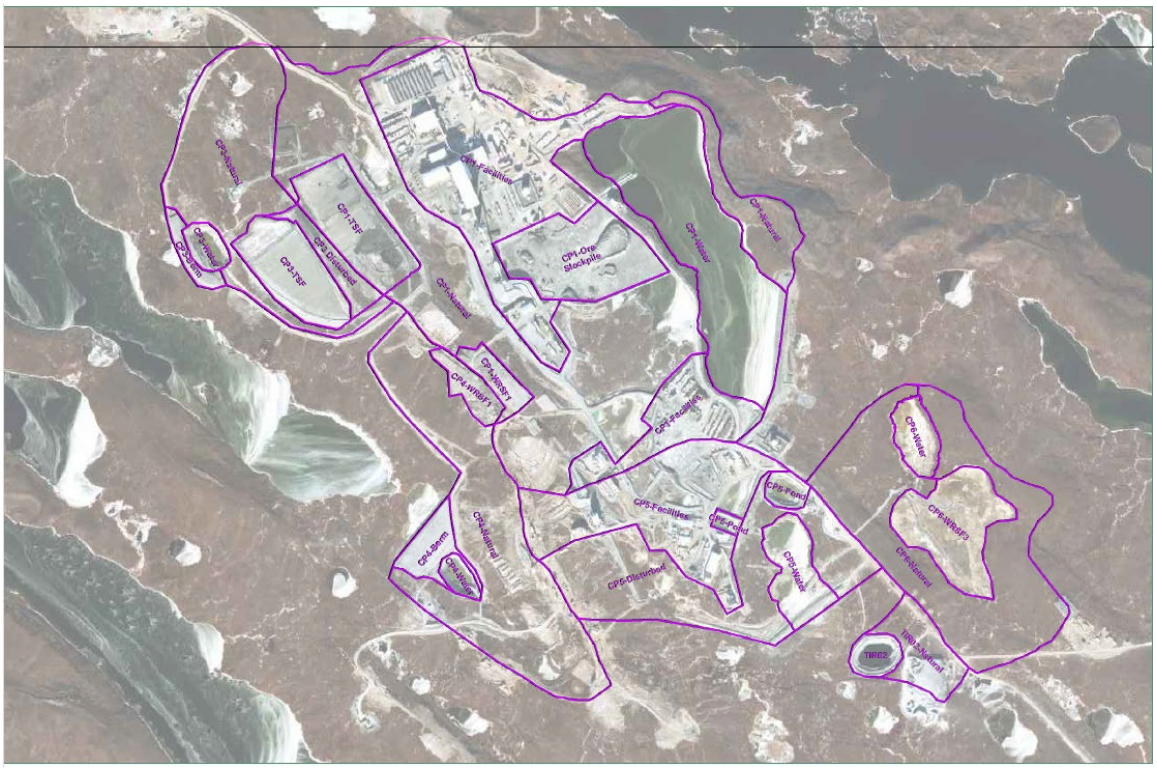

Figure 4-1: Meliadine Mine site layout and catchment delineation for 2019 based on aerial photo from October 2019.

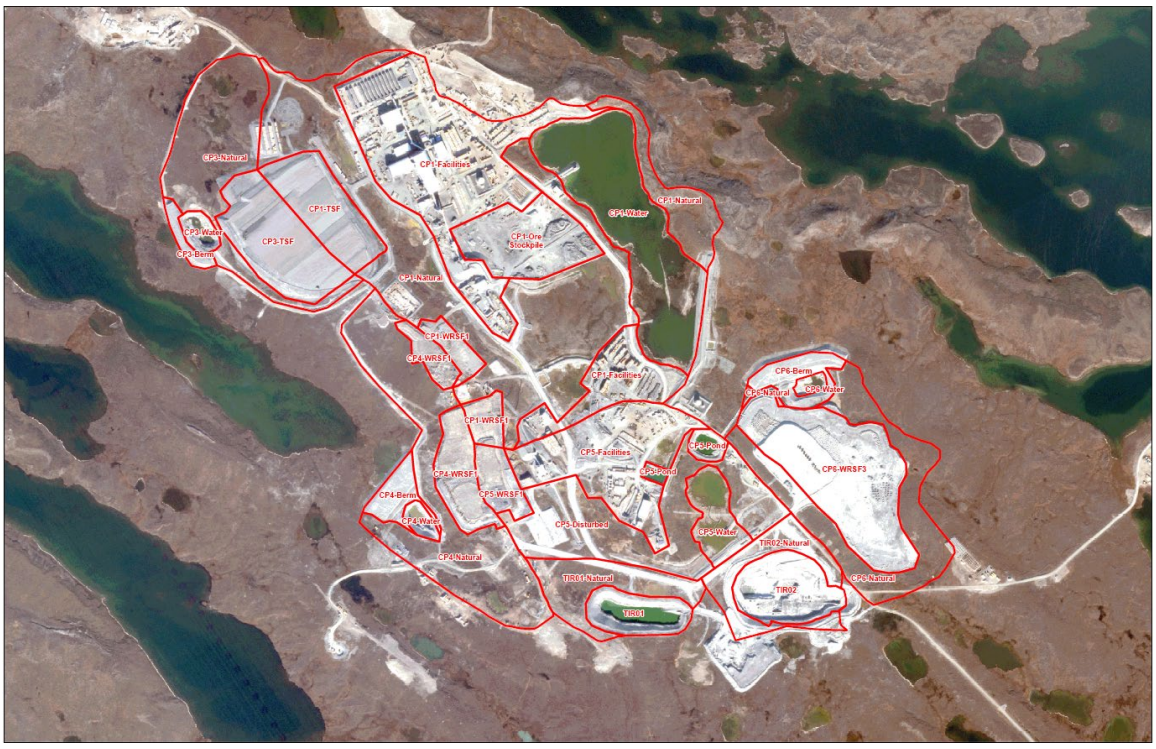

Figure 4-2: Meliadine Mine site layout and catchment delineation for 2020 based on aerial photo from September 2020.

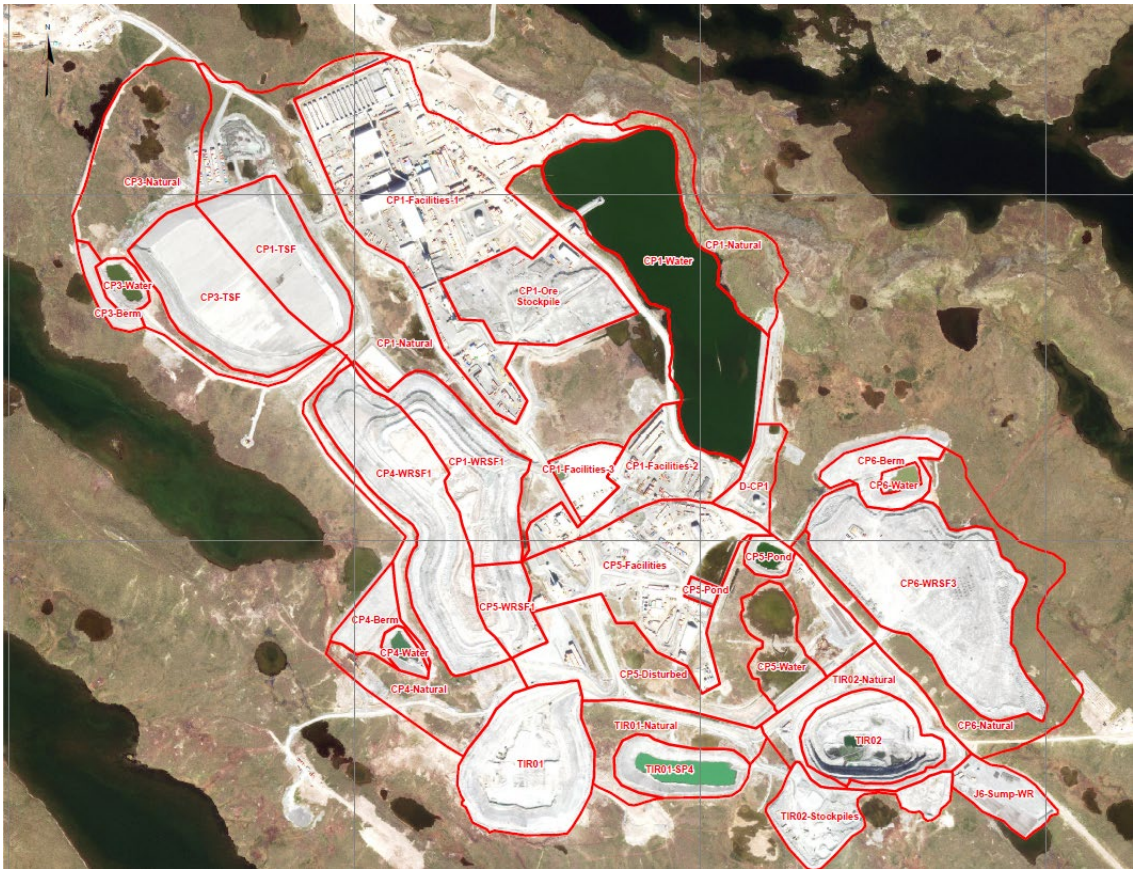

Figure 4-3: Meliadine Mine site layout and catchment delineation based on aerial photo from July 2021.

This WBWQM is constructed in GoldSim and designed to predict water quality at the following collection nodes:

- CP1 collection pond is the final collection point prior to discharge to Meliadine Lake via treatment at the effluent water treatment pond (EWTP). This collection pond receives drainage from the mine facilities area, ore stockpiles, TSF, WRSF1 and WRSF3.
- Channel 1 is a constructed ditch that drains much of the mining area, including the TSF, a portion of WRSF1, the plant site area and ore pads, into CP1.
- CP4 collection pond receives drainage from WRSF1 and the surrounding disturbed areas.
- CP3 collection pond receives drainage from the TSF and the surrounding disturbed areas.
- CP6 collection pond receives drainage from WRSF3 and the surrounding disturbed areas

Tiriganiaq Underground source term is validated outside of the WBWQM, as sump monitoring data can directly be compared to source term predictions (Appendix A).

The results for Channel 1 and CP1 represent composite drainage chemistry from mine surface facilities. Validation results for these model nodes are provided in Figure 4-4 and Figure 4-5, respectively, while complete validation results for all model nodes are provided in Appendix A.

Overall, the validation model shows that calibrated source terms conservatively predict water quality at CP1, particularly for arsenic (As), Ammonia (NH_3), copper (Cu), selenium (Se) and nickel (Ni). The observed concentrations of these elements are significantly overestimated by the validation model in most months. Results for NH_3 are initially underestimated in 2019 shortly after model initiation but are then overestimated from 2020 onwards. Validation of this parameter in CP1 is complicated by attenuation processes impacting NH_3 such as oxidation and biological uptake which are not incorporated in the model. A number of T-CN values are underestimated in 2019-2021, which could be impacted by model initialization the elevated T-CN method detection limit during this time period. Lower T-CN detection limits starting in 2022 show better validation and Channel 1 data shows the range of T-CN concentrations is captured at this upstream monitoring point which is closer to the point source (TSF) of T-CN loading (Figure 4-5).

The validation results for Channel 1 generally reflect the range of observed concentrations (Figure 4-5). The validation model overestimates observed SO_4 in the spring, indicating that the model overestimates runoff concentrations during the freshet, which may be a relic of applying annual average source term concentrations. The range of trace metal concentrations are generally conservatively captured, with the exception of a series of anomalously high Ni concentrations in 2019. The validation model conservatively estimates most Ni concentrations at Channel 1 in 2021 (Figure 4-5), and significantly overestimated Ni in CP1 (Figure 4-4), providing confidence that this parameter is conservatively captured.

Overall, the validation exercise shows that the calibrated water balance and source terms are able to conservatively reproduce most observed concentrations in site monitoring data.

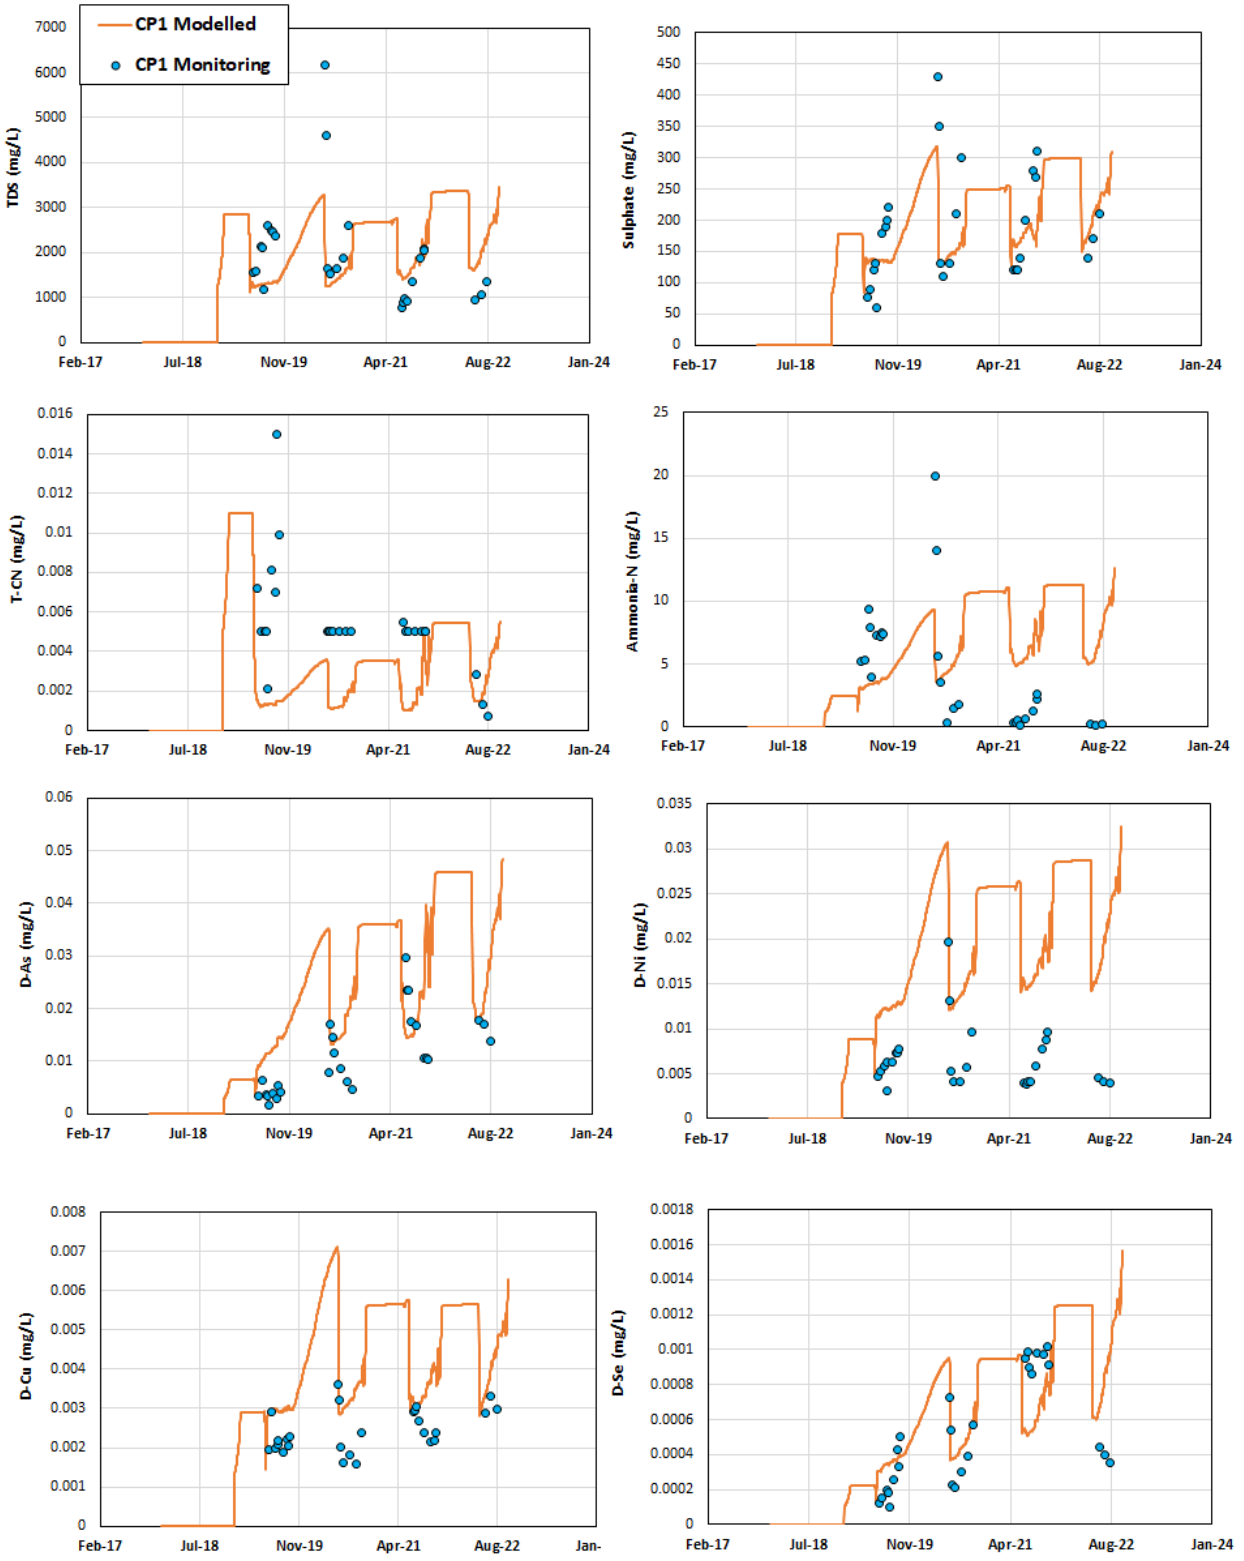

Figure 4-4: Validation results for CP1.

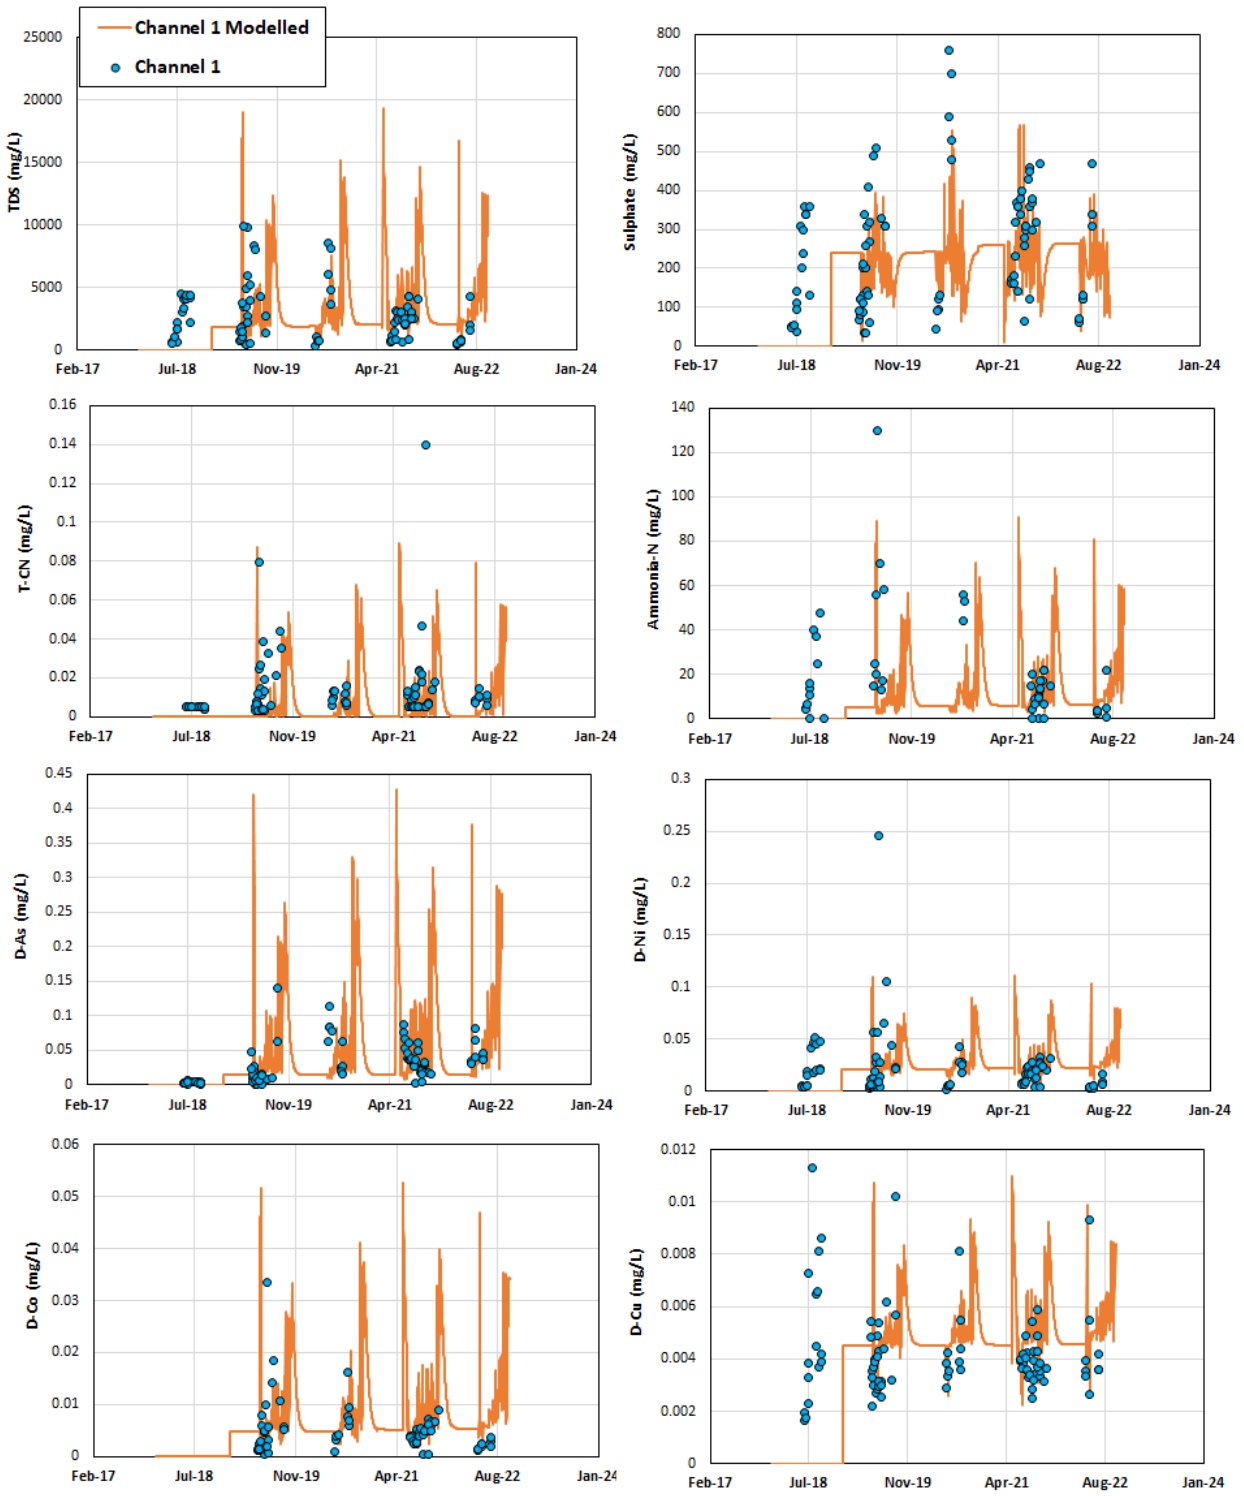

Figure 4-5: Validation results for Channel 1. Channel 1 monitoring data plotted in this figure includes sampling of upstream culverts 'Culvert 2 and Culvert 3' as well as the Channel 2 tributary.

5. Source Term Results

Source terms are developed on an annual time step for each mine component. The temporal trends for TDS and As are illustrated for WRSFs, the TSF, Open Pits, and underground mines in Figure 5-1, Figure 5-2, Figure 5-3 and Figure 5-4, respectively. The complete set of source term parameters are provided in Appendix B.

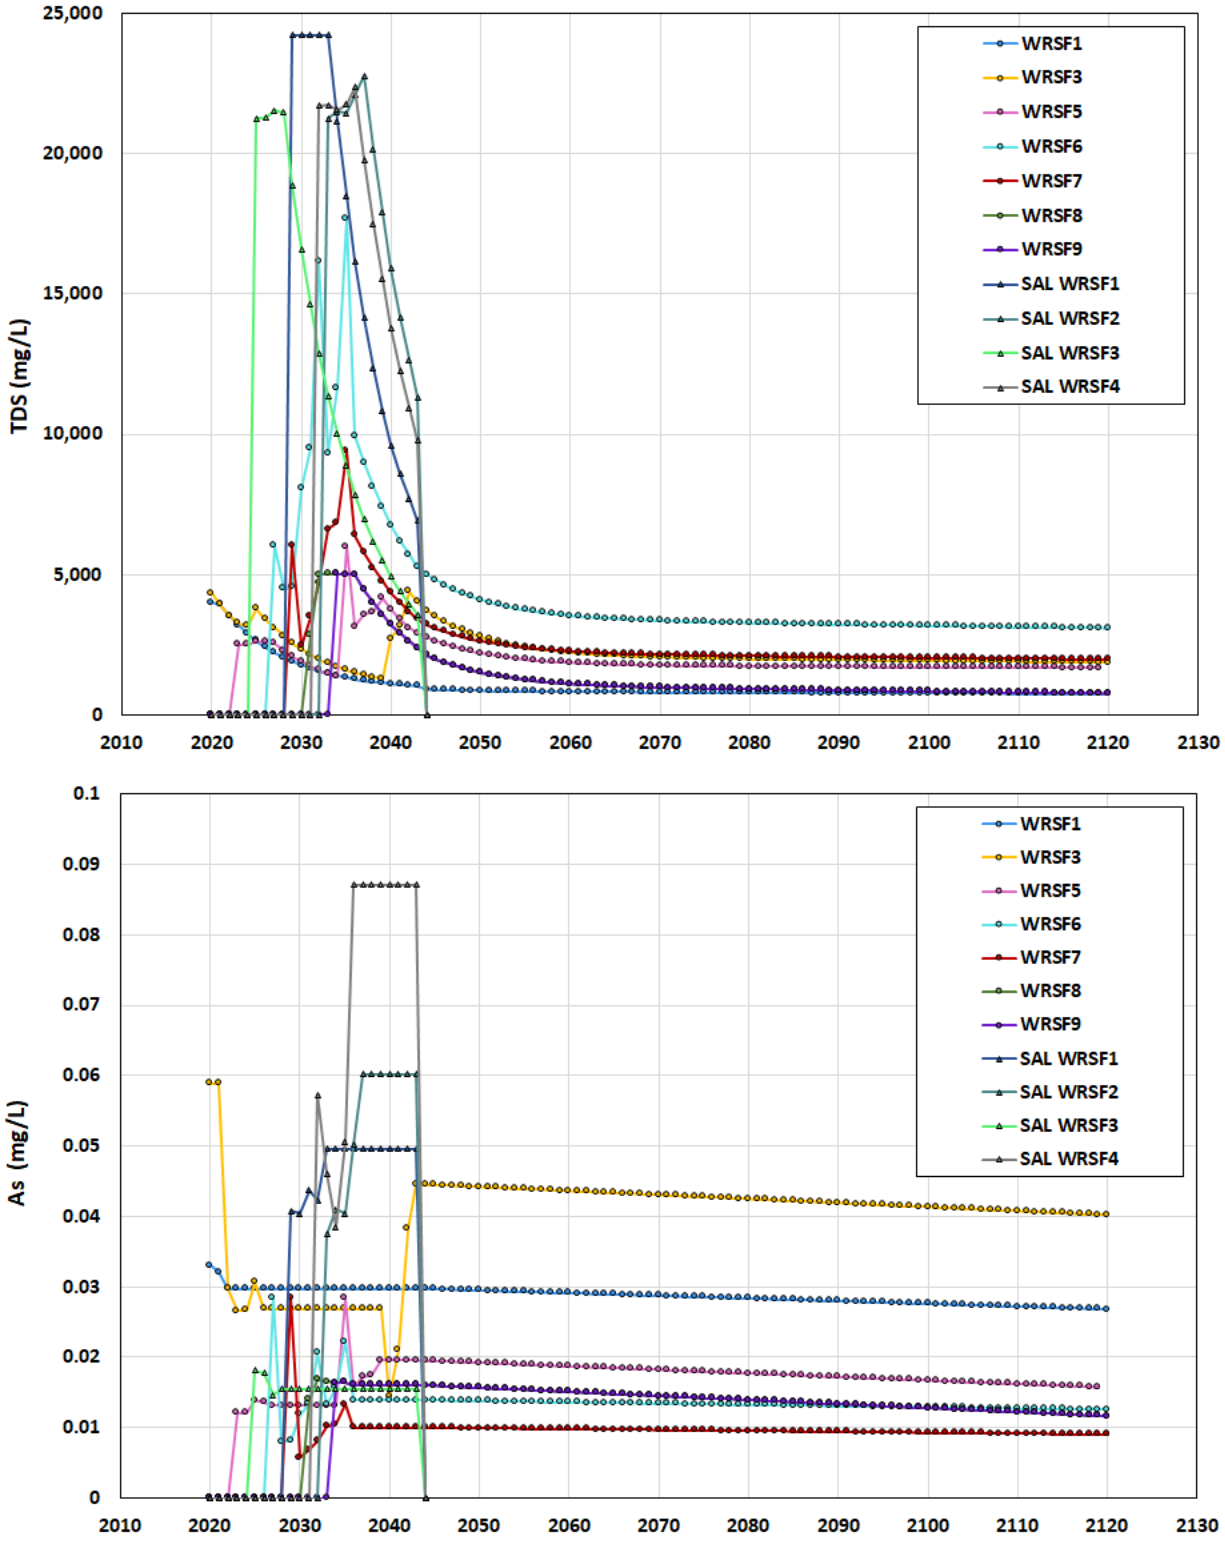

Figure 5-1: Waste rock storage facility annual source term for TDS (top) and As (bottom).

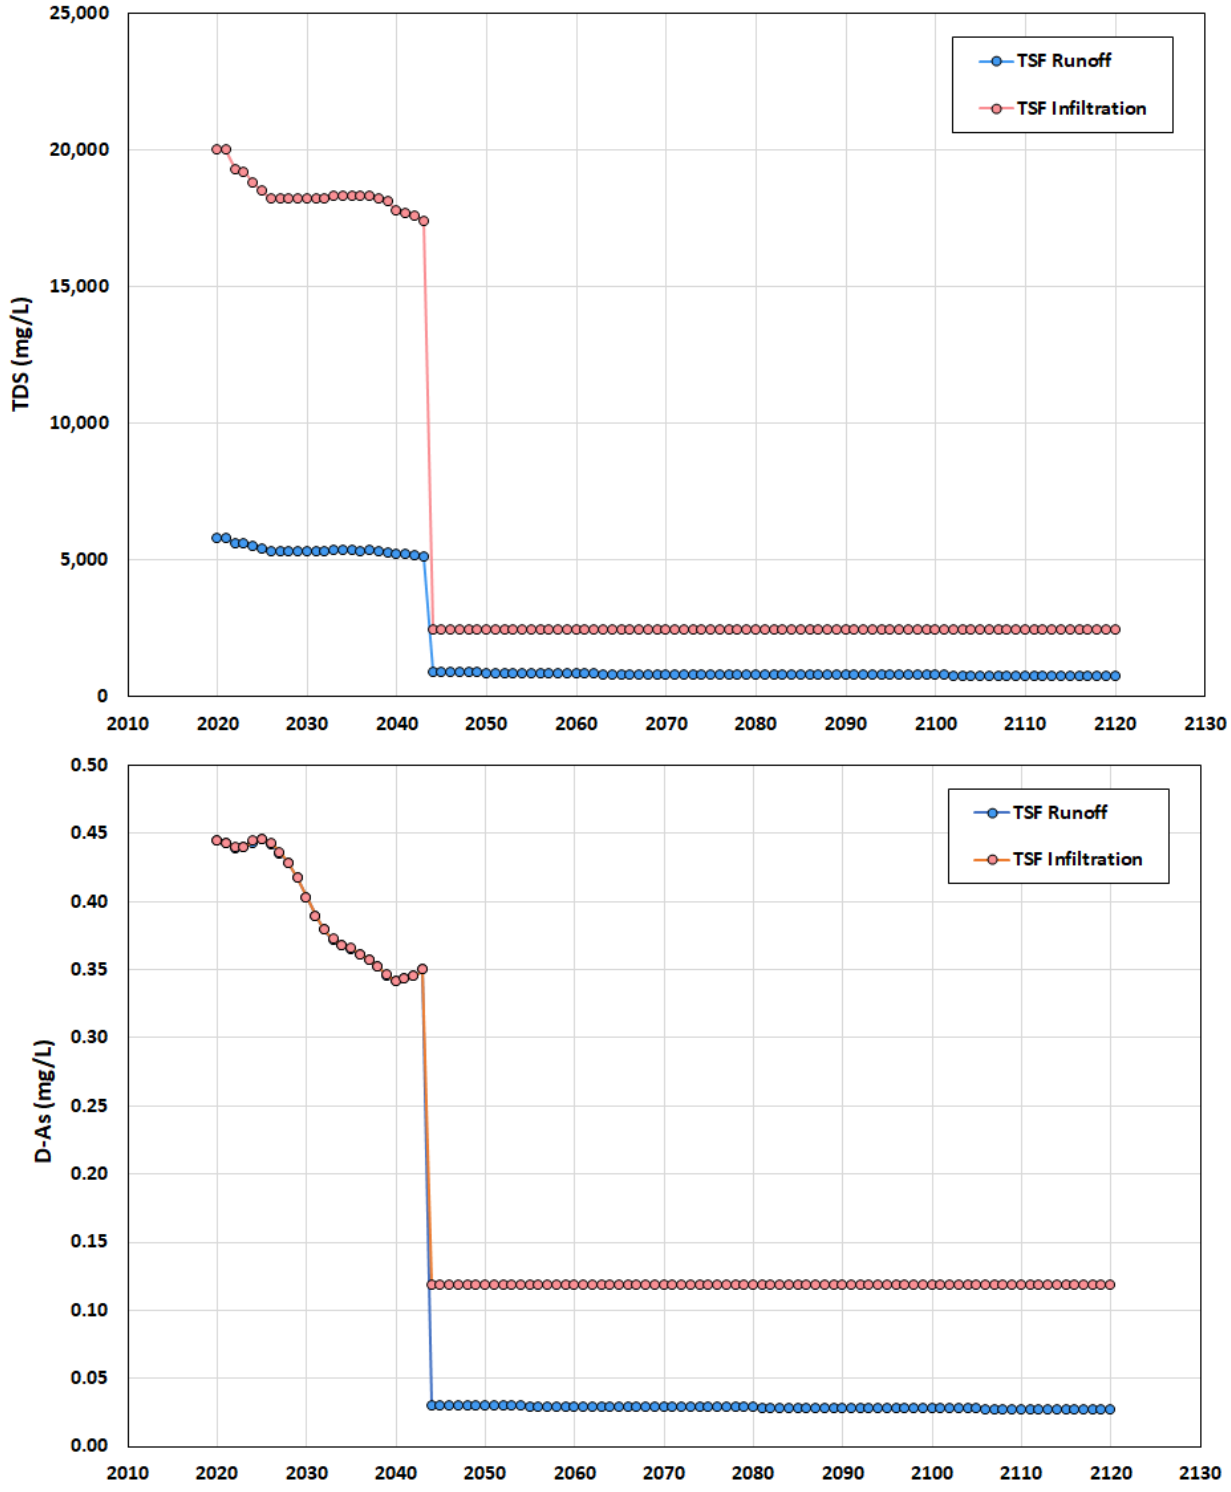

Figure 5-2: Tailings storage facility annual source terms for TDS (top) and As (bottom).

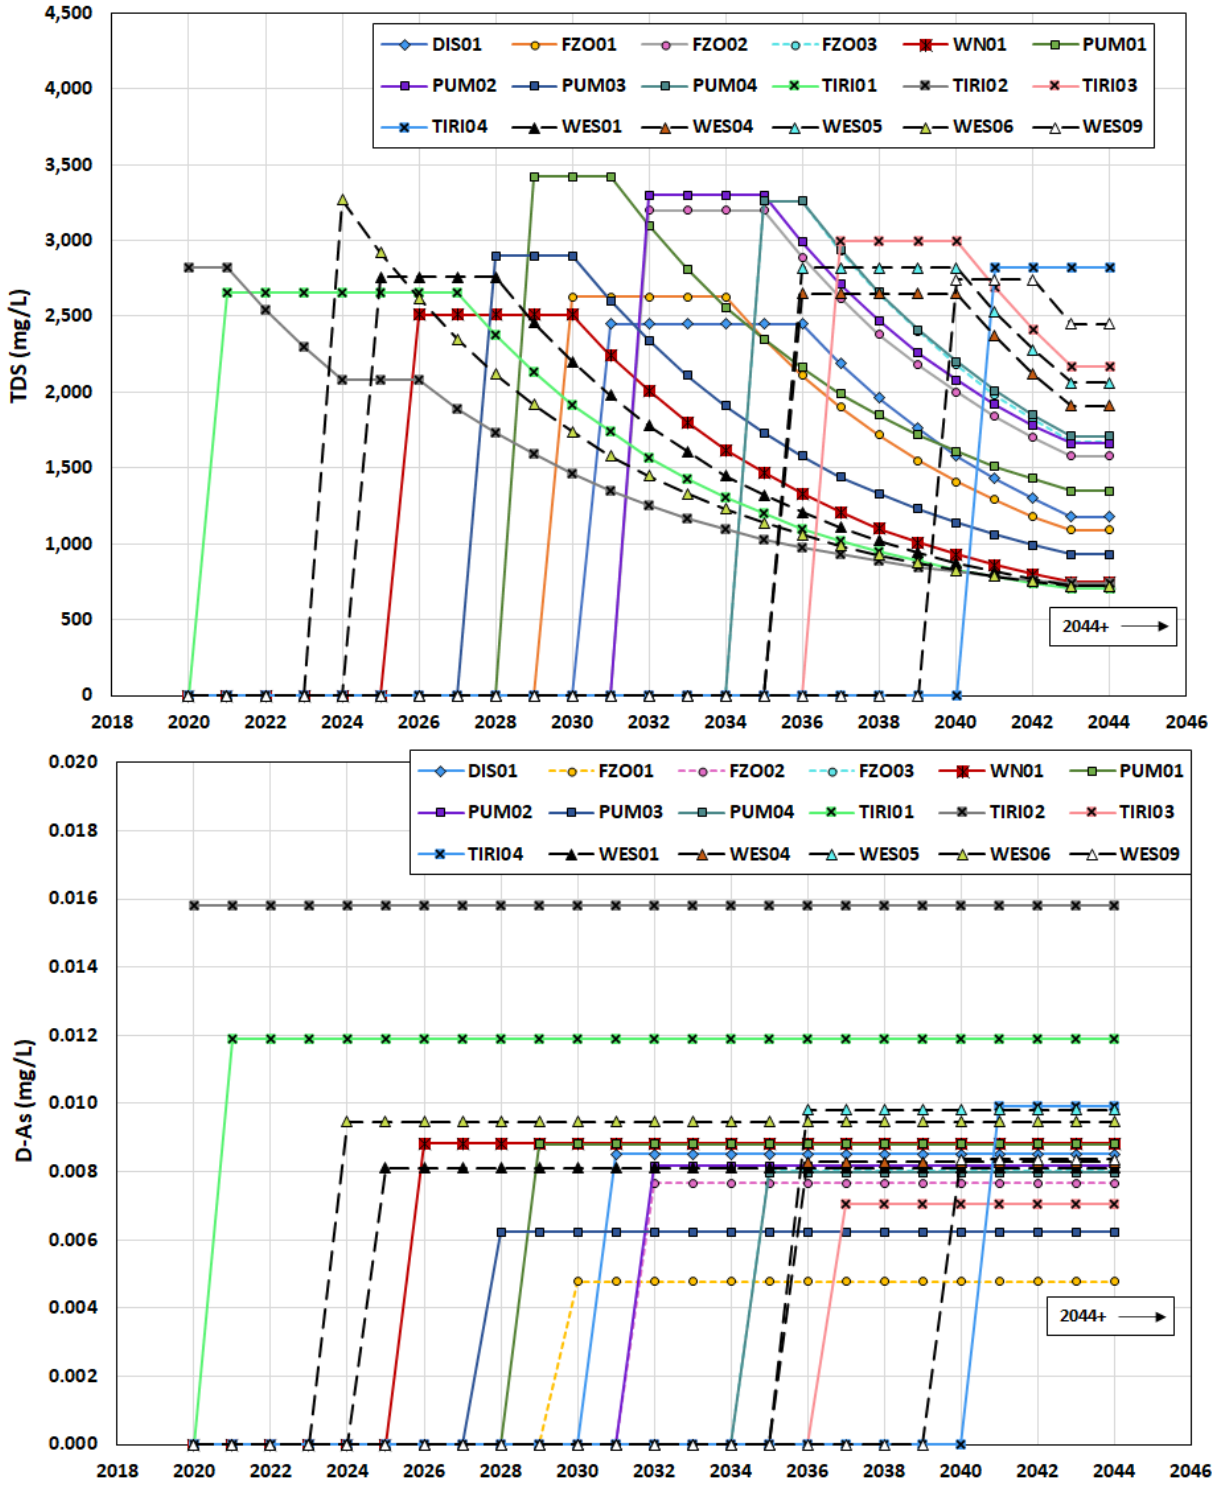

Figure 5-3: Pit wall annual source terms for TDS (top) and As (bottom).

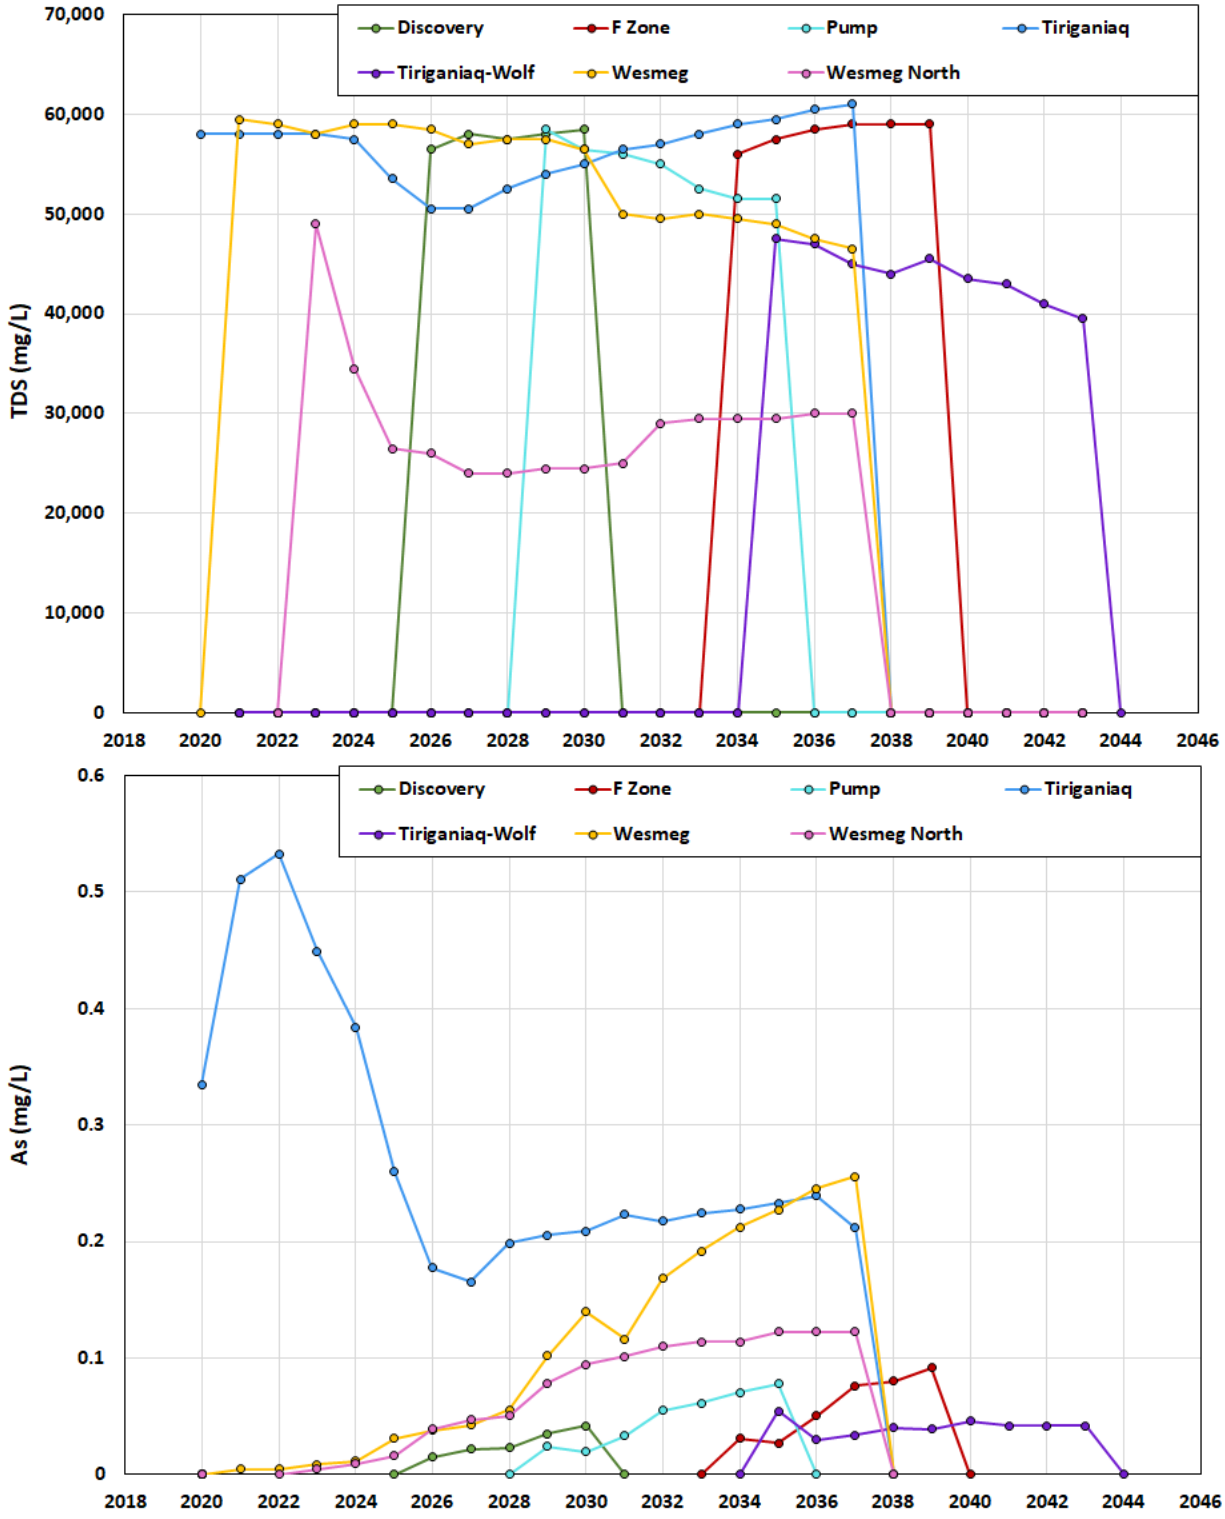

Figure 5-4: Underground mine source terms for TDS (top) and As (bottom).

6. Closure

We trust that this memo meets your expectations. Please contact the undersigned with any questions or comments.

Respectfully,
Lorax Environmental Services Ltd.
