[1] MMER 2006 update. Maximum authorized monthly mean concentration.
[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium ion.
In the above table, the Cr(VI) criterion of 0.001 mg/L is shown.
[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness value of 50 mg/L assumed (no minimum value provided)
[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

[1] MMER 2006 update. Maximum authorized monthly mean concentration.

[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium ion.
In the above table, the Cr(VI) criterion of 0.001 mg/L is shown.

[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness value of 50 mg/L assumed (no minimum value provided)

[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

[1] MMER 2006 update. Maximum authorized monthly mean concentration.

[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium ion.
In the above table, the Cr(VI) criterion of 0.001 mg/L is shown.

[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness value of 50 mg/L assumed (no minimum value provided)

[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

**Notes:**

nc: not calculated

[1] MMER 2006 update. Maximum authorized monthly mean concentration.

[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium ion.
In the above table, the Cr(VI) criterion of 0.001 mg/L is shown.

[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness value of 50 mg/L assumed (no minimum value provided)

[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

**Notes:**
nc: not calculated
[1] MMER 2006 update. Maximum authorized monthly mean concentration.
[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium ion. In the above table, the Cr(VI) criterion of 0.001 mg/L is shown.
[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness value of 50 mg/L assumed (no minimum value provided)
[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

| Wolf CN4 CND residue | 2011 | whole ore | Wolf | open pit | x | x | x | x | x | x | x |

**Notes:**

Whole rock was completed using Borate fusion and XRF methods.

ICP = Metals (including arsenic and selenium) by inductively coupled plasma-mass spectroscopy (ICP-MS), with samples extracted using a strong acid solution.

Mercury by cold vapour atomic absorption spectroscopy (CVAAS), EPA245.1 methodology

ABA = Acid Base Accounting (modified Sobek method(1996)) - paste pH, NP, total sulphur, sulphate, sulphide, total carbon, total inorganic carbon, and carbonate

SFE = Shake Flask Extraction according to Modified ASTM D3987; 4:1 solution to solid ratio, 24 hour shake (2001)

NAG: Net Acid Generation; single addition NAG pH and leachate (AMIRA, 2002)

HCT = Humidity Cell Test

PW = Process Water.  Analysis of cyanide species plus total and dissolved metals.

# C.2 Chemical Composition Results: Tables and Figures

# Appendix C.2: Whole Rock Analysis and ICP Results

Notes:

S(T)=Total Sulphur; S(SO4)=Sulphate Sulphur; S(S2-)=sulphide sulphur; TC = Total Carbon; TIC=Total Inorganic Carbon

CaNP = Carbonate Neutralization Potential (based on $CO_3$ content); CaNP-adj = Carbonate mineral Neutralisation Potential (based on CO3 content proportion according to average mineralogy); NP = Neutralization Potential; AP = Acid Potential based on total sulphur content

ARD = Acid Rock Drainage; NPR = Net Potential Ratio (NP/AP); CaNPR-adj = (CaNP-adj/AP); Net NP = Net Neutralisation Potential (NP-AP); Net NP-ad = (CaNPadj-AP); PAG = Potentially Acid Generating

[1] ARD potential based on INAC (1992) and MEND (2009) using CaNPR-adj and NPR (i.e. where different ARD potentials are defined the unit is considered uncertain).

Notes:

nc: not calculated

[1] MMER 2006 update. Maximum authorized monthly mean concentration.

[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium

[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness

[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

Notes:
nc: not calculated
[1] MMER 2006 update. Maximum authorized monthly mean concentration.
[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium
[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness
[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

Notes:
nc: not calculated
[1] MMER 2006 update. Maximum authorized monthly mean concentration.
[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium
[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness
[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

**Notes:**

Whole rock was completed using Borate fusion and XRF methods.

ICP = Metals (including arsenic and selenium) by inductively coupled plasma-mass spectroscopy (ICP-MS), with samples extracted using a strong acid solution.

Mercury by cold vapour atomic absorption spectroscopy (CVAAS), EPA245.1 methodology

ABA = Acid Base Accounting (modified Sobek method(1996)) - paste pH, NP, total sulphur, sulphate, sulphide, total carbon, total inorganic carbon, and carbonate

SFE = Shake Flask Extraction according to Modified ASTM D3987; 4:1 solution to solid ratio, 24 hour shake (2001)

Notes:

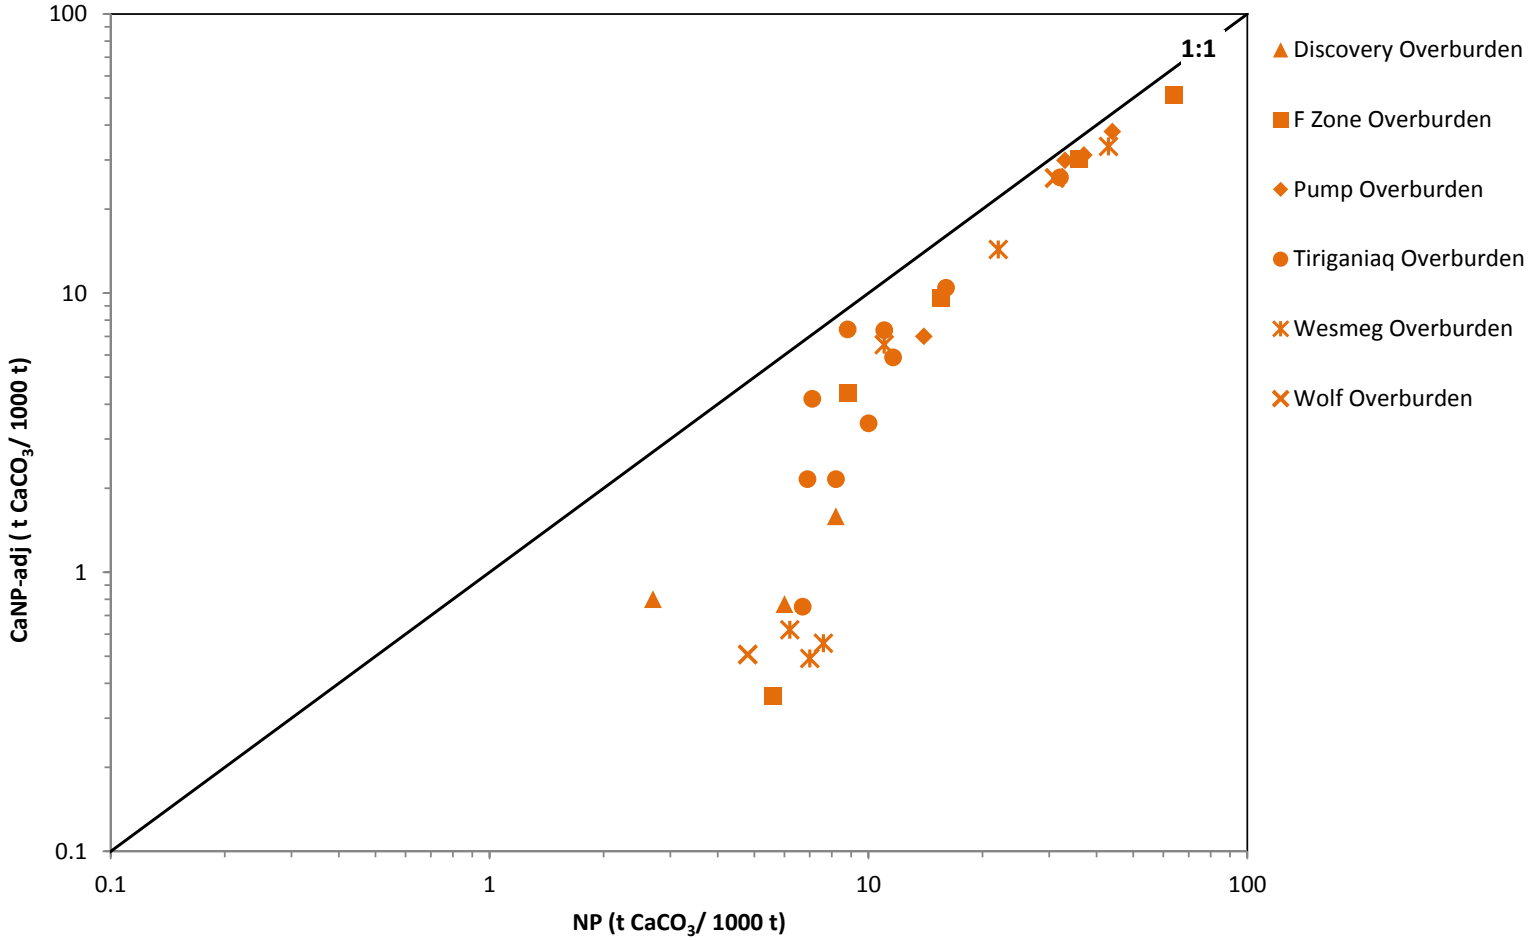
S(T)=total sulphur; S(SO4)=sulphate sulphur; S(S2-)=sulphide sulphur; TC = Total Carbon; TIC=total inorganic carbon

CaNP = carbonate neutralization potential (based on $CO_3$ content); NP = neutralization potential; AP = acid potential

ARD = Acid Rock Drainage; NPR = Net Potential Ratio (NP/AP); Net NP = Net Neutralisation Potential (NP-AP); PAG = Potentially Acid Generating

[1] ARD potential based on INAC (1992) and MEND (2009) using CaNPR and NPR (i.e. where different ARD potentials are defined the unit is considered uncertain).



Bulk ARD = Sum NP/Sum AP

Note:
$S^{2-}$ values less than method detection limit (MDL) are plotted as MDL values ($S^{2-}$ = 0.01%)

Notes:
nc: not calculated
[1] MMER 2006 update. Maximum authorized monthly mean concentration.
[2] CEQG Freshwater aquatic life criteria for chromium depends on the valence of chromium ion.
In the above table, the Cr(VI) criterion of 0.001 mg/L is shown.
[3] CEQG Freshwater Aquatic Life Criteria are hardness dependant. Minimum value stated, for cadminum, hardness value of 50 mg/L assumed (no minimum value provided)
[4] CEQG Freshwater Aquatic Life Criterion for aluminun is pH dependant; assumes pH>6.5.

# D.4: Shake Flask Extraction Results
## Overburden - All Deposits
## Meliadine Property, Nunavut
## Agnico-Eagle Mines Ltd.

## 1 Introduction

Comaplex Minerals is considering an underground exploration program in support of scoping studies for development of the Tiriganiaq gold deposit in Nunavut. The program would include excavation of an approximately 500 metre decline to gain access to the ore zones. The purpose of the program would be to confirm the continuity and grade of the ore lodes, and to obtain bulk sampling for metallurgical testing. Development of the underground decline will likely require a Class B water licence from the Nunavut Water Board. To support this application, Comaplex has asked SRK to provide an assessment of the potential for acid rock drainage and metal leaching from the waste rock, including recommendations for management of this material, and preliminary estimates of water quality.

Previous geochemical testing of the ore and waste rock was completed in conjunction with metallurgical testing programs completed in 1998 and 2001. The results indicated a mixed potential for acid rock drainage and metal leaching, with most of the hanging wall rock samples classified as non-acid generating, and most of the ore zone samples classified as having an uncertain potential for ARD. Further testing was recommended to improve the geological and spatial coverage of the sampling.

A supplemental testing program was initiated by SRK in November 2005. The first part of the program included acid base accounting to characterize the potential for ARD, and solids metal analyses to characterize the metal content of the samples. A limited number of these samples were selected for short-term leach extraction tests. This memo summarizes the results of the available testing data.

## 2 Geology and Mineralogy

A detailed description of the geological setting, the deposit geology and mineralogy is provided in a 2005 report by Strathcona Mineral Services Ltd. Features relevant to the geochemical assessment are summarized as follows.

The Tiriganiaq deposit is part of the Meliadine West property located approximately 25 km west northwest of Rankin Inlet. Rocks on the Meliadine West property are part of the Archean aged Rankin Inlet Greenstone belt. Gold mineralization at Tiriganiaq is principally hosted by a mesothermal quartz-vein dominated gold system occurring in a strongly sheared package of Archean turbiditic sediments and iron formations. The deposit is comprised of multiple loads of mineralization over a strike length of up to 1.5 km, sub-divided into the Tiriganiaq Main and West Zones. The mineralization is parallel to the dominant shear fabric that strikes east-west, and dips to

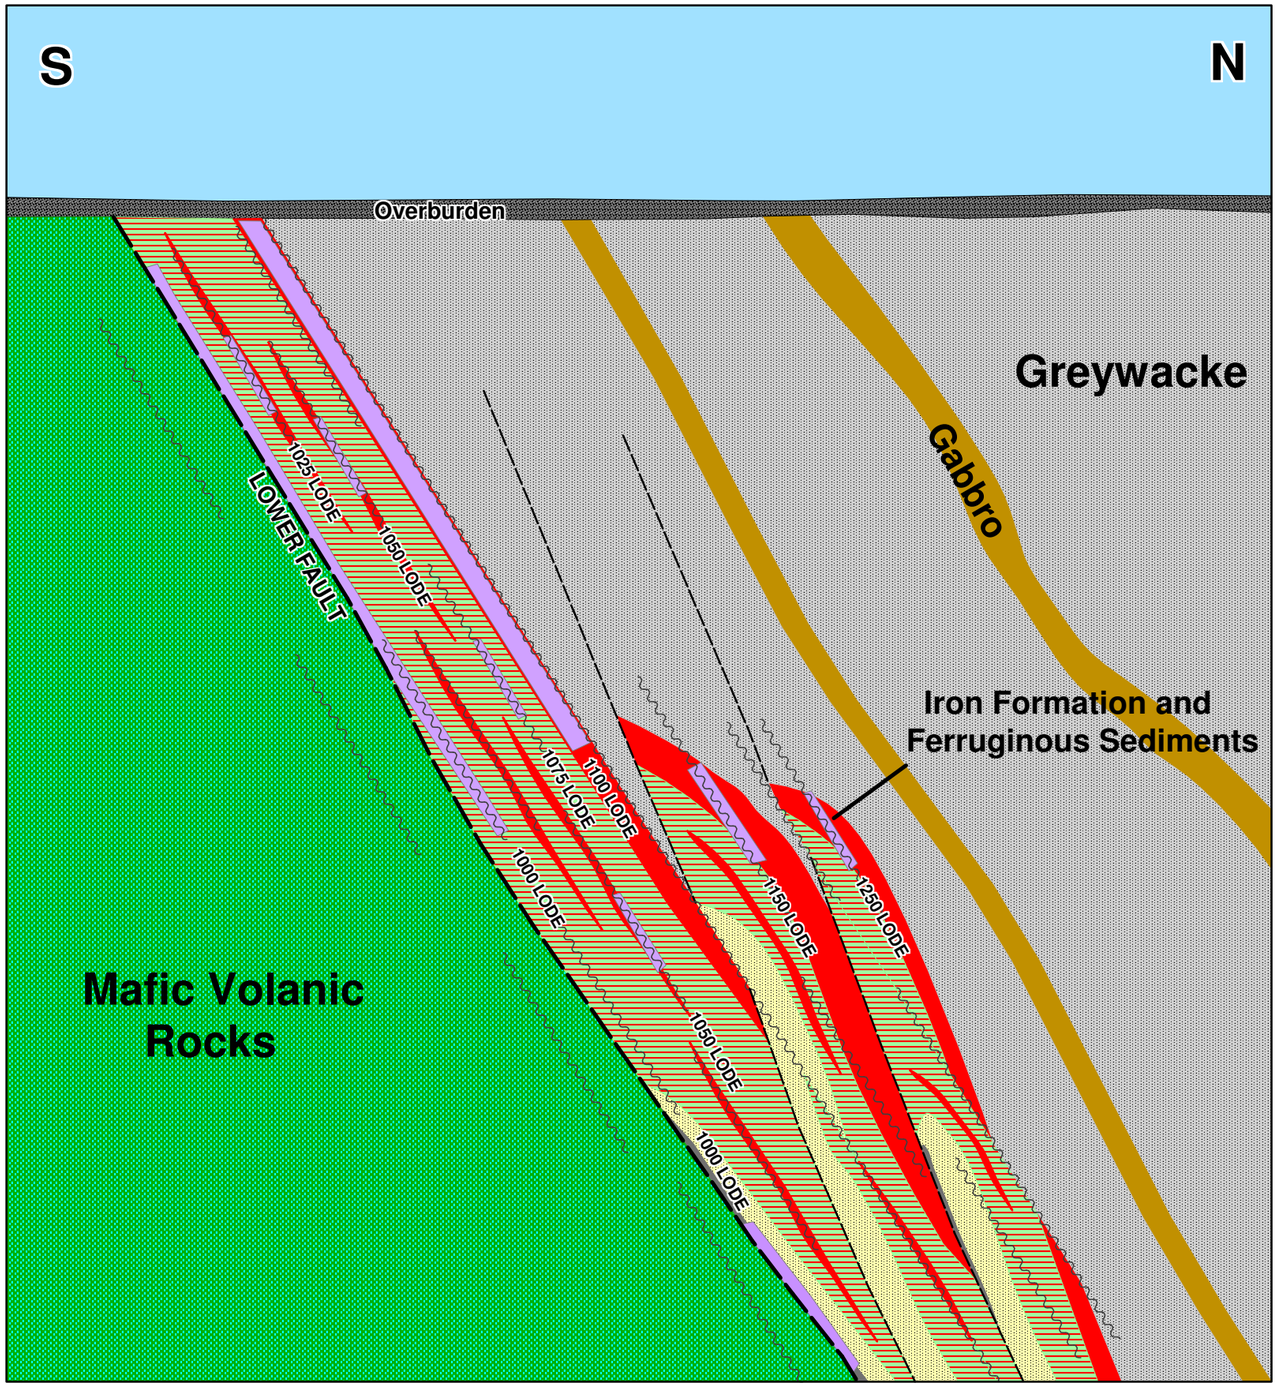
the north at an average angle of 60°. All of the rocks in the deposit area have been subjected to low to mid-grade greenschist grade metamorphism.

A typical cross section of the deposit is shown in Figure 1. The stratigraphic sequence is as follows:

- The structural hanging wall is comprised of clastic turbidite sediments of variable grey coloured greywacke-siltstone-mudstone beds from the **Sam Formation**, ranging in thickness from centimetres to decimetres. This unit also contains minor amounts of argillite.

- The Sam Formation overlies a diverse package of iron-rich rocks with interbedded magnetite, chert, chloritic mudstone and greywacke from the **Upper Iron Formation**. The top of this unit is marked by a laterally continuous iron formation. This unit is often mineralized.

- The **Tiriganiaq Formation** is comprised of finely laminated siltstone. It is commonly altered to a yellowish grey colour by sericite alteration, particularly near the contact with the Lower Fault. Graphitic argillite occurs sporadically near the base of this sequence, and is often coincident with the Lower Fault zone, which demarks the contact with the underlying Wesmeg Formation.



- The **Wesmeg Formation** is comprised mafic volcaniclastics, comprising the structural footwall of the deposit. These rocks are chlorite-rich near the Lower Fault, they can be highly schistose and sericite-carbonate altered.

Tiriganiaq is only one of several known gold occurrences on the property that occur near the faulted contact of sediments and mafic volcanic rocks. The Wolf North deposit located 3.5 km to the west is also associated with this contact, and is geologically analogous to this deposit. Other deposits on the property such as F, Pump, and Wolf Main differ in that they are hosted in lean, chert-rich, magnetite poor iron formations hosted in the Wesmeg Formation.

Gabbro dykes and sills of several ages as well as minor lamprophyre dykes are recognized on the Meliadine West property.

The proposed underground decline will be collared in the Sam Formation, and will ramp towards the ore zones. Therefore, most of the waste rock that will be produced will be from the Sam Formation. The relative proportions of each rock type will need to be defined for the water licence application.

Gold mineralization is directly associated with quart veins varying from thick laminated veins to wispy erratic stringers and stockwork. In general, quartz and quartz-ankerite veins tend to be mineralized, while quartz-calcite veins are commonly barren. Sulphide minerals occur in two main assemblages. The first, often associated with the iron formation and black argillite, includes wispy discontinuous laminations of pyrrhotite, pyrite, and chalcopyrite, typically parallel to the bedding. The second consists of coarse-grained clots of arsenopyrite and pyrrhotite associated with the quartz veining and gold mineralization. Both assemblages host minor local concentrations of galena and lesser amounts of sphalerite. Areas with strong gold mineralization are associated with hydrothermal sericite alteration. Coarse grained aggregates of carbonate often occur in conjunction with the quartz veins.

## 3 Review of Earlier Testing Data

Acid base accounting data is available for ore, waste rock and overburden samples from the Tiriganiaq deposit. The testing was completed by Lakefield Research in conjunction with the metallurgical testing programs. Information on the testing programs was presented in a 1998 submission by WMC International Ltd., and reports by Lakefield Research. The testing programs are summarized as follows:

- 3 samples representing quartz vein type ore (Melmet 2), iron formation type ore (Melmet 3), and a sample representing the complete ore profile (Melmet 1) were tested in April 1997.
- 2 samples representing iron formation ore (Comp 1-3) and quartz vein type ore (Comp 4-5) were tested in January 1998. Metallurgical testing was also completed on these samples, and duplicate samples of the process residues were also produced.
- 18 samples of waste rock were tested in May 1998. These included 3 greywacke, 4 argillite and 2 mixed greywacke and argillite samples from the hanging wall, 3 unmineralized iron formation samples from the ore zone, and 6 volcanic samples from the footwall.
- 7 samples of overburden were collected from surficial material in this area.

Two ore samples from the nearby Wolf North deposit were also characterized in a 2001 metallurgical testing program by Lakefield Research (April 2001), and are relevant due to the similarity between this deposit and Tiriganiaq.

The locations of the samples are provided in Figures 2 and 3.

The results for these samples are provided in Appendix 1.

Ore samples had consistently alkaline paste pH's (8.2 to 8.8), moderately high carbonate concentrations (5.9% to 8.4%), and moderately high neutralization potentials (NP) (79 to 139 kg$CaCO_3$-eq/tonne). The NP and the carbonate content were strongly correlated, suggesting that the NP occurs primarily as carbonate minerals. This is consistent with the mineralogy of the deposit. Sulphur concentrations were also elevated (0.9% to 4.4%), with most of the sulphur occurring as sulphide, resulting in moderately elevated acid potentials (AP). The samples had consistently positive net neutralization potentials, and NP/AP ratios between 1.1 and 6.3, indicating that some samples had an uncertain potential for ARD, while others would likely be non-acid generating. In the absence of kinetic testing data, an NP/AP ratio of less than 3 is typically used as an indication that samples could have potential for acid generation, while samples with NP/AP ratios of less than 1 are considered likely to be acid generating. Three out of the five Tiriganiaq ore samples tested had NP/AP ratios between 1 and 3. The other two Tiriganiaq samples and both of the Wolf North samples had NP/AP ratios of greater than 3.

Waste rock samples also had consistently alkaline paste pH's and moderate to high neutralization potentials. In general, NP's were lower (45 to 118 kg $CaCO_3$ eq/tonne) in the hanging wall rocks than in the volcanic footwall rocks (219 to 296, with one outlier of 44 kg $CaCO_3$ eq/tonne). Sulphur concentrations ranged from 0.01% to 6.81%, with most samples having less than 0.5% sulphur. The sulphur occurred primarily as sulphide. Two of the hanging wall argillite samples had sulphide concentrations of 4.75 and 6.81% respectively and were noted to be from a fault zone and a zone of intense quartz/pyrrhotite veining respectively. These two samples had NP/AP ratios of less than 1, and NNP's of -35 and -95 kg $CaCO_3$ eq/tonne, and were classified as potentially acid generating. The other sixteen samples, including 7 hanging wall samples, 4 iron formation samples, and six volcanic samples had NP/AP ratios of greater than 3. The data indicate that the majority of the waste

rock is likely to be non-acid generating. However isolated zones of acid generating rock are likely to be present. Further testing was recommended to improve the spatial coverage of the sampling.

Overburden samples had negligible sulphur concentrations (0.01 to 0.02%) and low NP's (5 to 11 kg$CaCO_3$ eq/tonne, resulting in NP/AP ratios consistently greater than 10. The results indicate they are likely non-acid generating, but that they have limited excess buffering capacity.

# 4 Supplemental Testing Program

## 4.1 Samples

Samples were selected for testing by Comaplex minerals to represent the stratigraphy that the underground decline is likely to cross. A total of 48 samples were selected from diamond drill core from 1998, 2000 and 2004 drilling programs. The sample intervals were typically 5 metres long. The locations of the samples are shown in Figures 2 and 3. The list of target samples was reviewed by SRK.

A continuous quarter split section of core representing the entire interval selected was provided to the testing laboratory. Samples were sent to Canadian Environmental and Metallurgical Inc. (CEMI) for testing. An SRK geochemist examined the samples on receipt at the lab. The samples were typically competent and hard, and even the oldest samples showed little signs of oxidation and weathering. A rock saw had been used to prepare the quarter splits.

Both carbonate and sulphide minerals were observed in most samples. Calcite was observed in association with quartz veins and was confirmed by vigorous reaction with a 10% solution of hydrochloric acid. Carbonate was also likely present in the fine grained matrix of many samples, also indicated by reaction with hydrochloric acid. Ankerite was observed throughout the matrix of some of the more weathered volcanic samples. Sulphide minerals were typically disseminated or in clots distributed throughout the rock mass. In some samples, there was concentration of the sulphide minerals in the quartz veins. The most abundant sulphide minerals were pyrrhotite, pyrite and arsenopyrite. Lesser amounts of chalcopyrite and galena were found in some samples.

## 4.2 Testing Methods

### 4.2.1 Sample Preparation

Samples were jaw crushed to minus half inch. A representative portion of the samples was split from the jaw crushed material and pulverized for the assay tests. The remaining material was wetted by adding 50 mL of deionized water and the sample bags were loosely sealed to ensure some exchange of oxygen. The samples were stored for approximately 1 month at room temperature to condition them for extraction tests.

### 4.2.2 ABA and Elemental Analyses

All of the samples were submitted for acid base accounting and elemental analyses. The acid base accounting tests were completed using the Modified Sobek method, including analysis of paste pH, sulphur speciation, and inorganic carbon. The samples for elemental analyses were prepared using an aqua regia digestion, and were analyzed by ICP.

# Tiriganiaq ARD Samples Cross Section

### 4.2.3 Leach Extraction Tests

At Comaplex's request, SRK selected three waste rock samples from the December 2005 static testing program for leach extraction testing. The samples included one greywacke sample from the hanging wall sediments, one iron formation sample, and one mafic volcanic sample.

Use of extraction tests on fresh competent drill core is not generally recommended due to the limited surface area available for oxidation prior to testing. However, the conditioning described previously should have allowed some oxidation to occur on the freshly exposed surfaces, thereby improving the validity of the results.

Tests were completed using the shake flask extraction method on the minus ¼ inch jaw crushed and conditioned material. In brief, 250 grams of sample was mixed with 750 mL of ultrapure deionized water and was allowed to equilibrate for 96 hours. The pH and conductivity of the leachate was measured and the leachate was filtered and submitted for alkalinity, sulphate, and a full suite metals by ICP-MS.

## 4.3 Results and Discussion

### 4.3.1 Acid Base Accounting

The acid base accounting results are provided in Appendix 2.

All of the samples tested had slightly alkaline paste pH's and moderate to high amounts of neutralization potential and carbonate. The mafic volcanic rocks tended to have somewhat higher neutralization potential (228 to 289 kg $CaCO_3$ eq/tonne) compared to the sedimentary rocks and gabbro dykes (20.1 to 102 kg $CaCO_3$ eq/tonne) (Figure 4). A single iron formation sample had an NP of 77 kg $CaCO_3$ eq/tonne. The NP was strongly correlated with carbonate content (Figure 5). Carbonate concentrations tended to be somewhat higher than the neutralization potential in the Iron formation and mafic volcanic samples. This is an indication that some of the carbonate was occurring as iron carbonate minerals. Ankerite was noted on the logs for several of these samples, and is the likely source of the iron carbonate. Carbonate minerals were noted in several of the hand samples, particularly in association with the quartz veining. These reacted strongly in 10% hydrochloric acid, indicating that the carbonate mineral was likely calcite.

Sulphur concentrations were typically less than 0.5% and therefore acid potentials were less than 15 kg $CaCO_3$ eq/tonne, although one of the sedimentary samples, two of the volcanic samples and the iron formation sample had higher values. As shown in Figure 4, the majority of the waste rock samples have NP:AP ratios of greater than 3, indicating they have a negligible potential for ARD. Three of the sedimentary samples and the iron formation sample had NP/AP ratios in the range of 1 to 3. In the absence of kinetic testing data, these are considered to be potentially acid generating. Overall, the relatively small proportion of samples with potential for acid generation and the high NP content of all of the samples indicate that seepage from the waste rock pile is likely to remain neutral.

### 4.3.2 Elemental Analyses

Results of the elemental analyses are provided in Appendix 3.

The elemental analyses indicate that arsenic and sulphur concentrations in the waste rock samples are enriched in comparison to typical concentrations in the earth's crust. This is consistent with the presence of arsenopyrite in several of the samples. Other trace elements were less than 2x higher than normal crustal values.

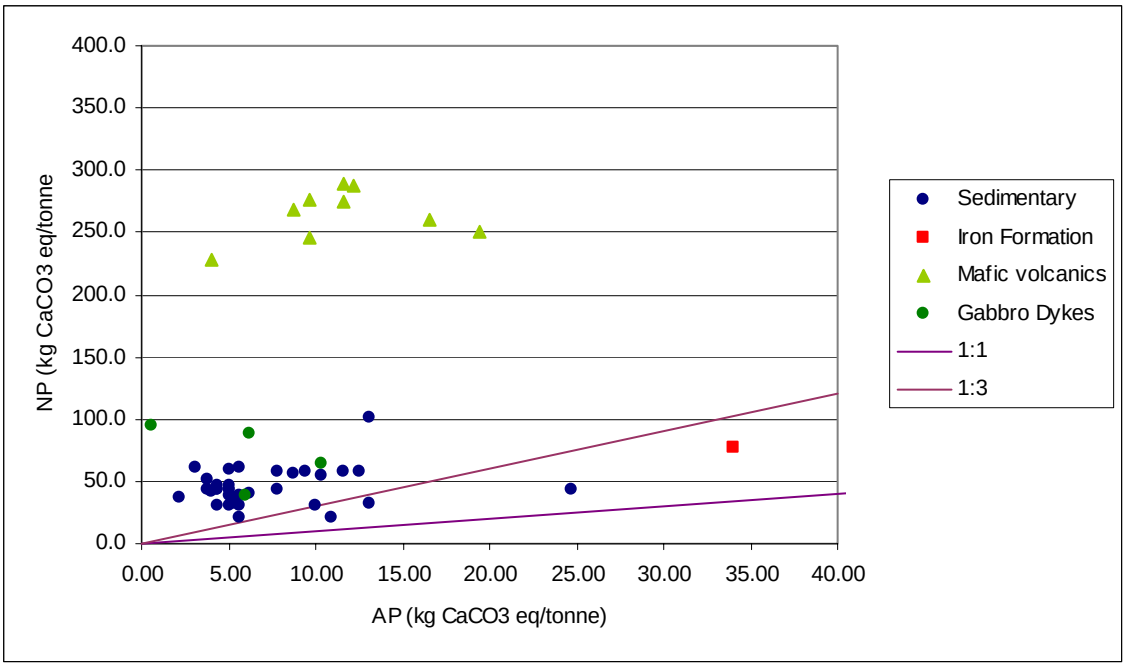

**Figure 4: Acid Base Accounting Results - NP versus AP**

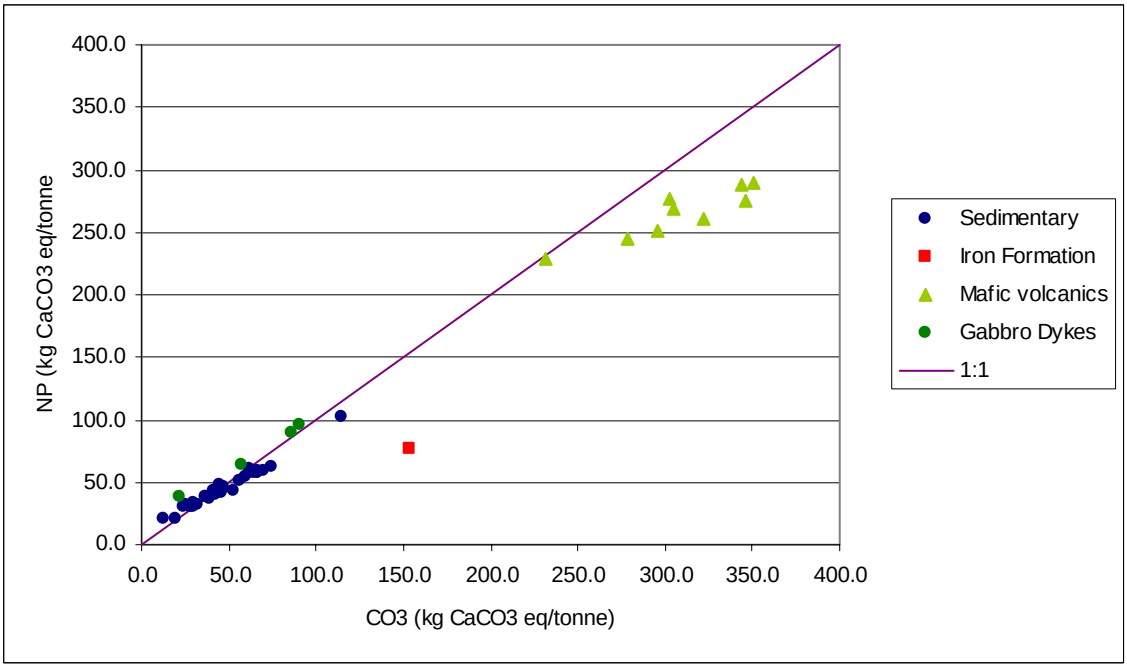

**Figure 5: Carbonate versus Modified Sobek NP**

The elemental analyses do not provide an indication of the solubility or rate of release of these elements from the waste rock. Arsenic and other trace elements such as copper, cobalt, nickel, and zinc may be mobilized as a result of sulphide oxidation. The rate of metal leaching will also be controlled by the rate of oxidation, the amount of waste rock, the grain size distribution of the rock, the iron content of the rock, and the local pH conditions. Because the pH conditions are expected to remain neutral, concentrations are not expected to be excessively high. However, it is possible that concentrations of some trace elements in seepage from the waste pile will exceed CCME guidelines for freshwater aquatic life. Further testing is therefore required to estimate the potential magnitude and rate of metal release from these materials.

### 4.3.3 Leach Extraction Test Results

The results are presented in Appendix 4. The results indicate the leachate had neutral pH's, moderate alkalinities, and relatively low sulphate concentrations (maximum of 21 mg/L was observed in the mafic volcanic sample). Trace element concentrations were generally low in comparison to typical mine waste samples. However, concentrations of aluminum, arsenic, copper and zinc were slightly elevated compared to CCME aquatic life guidelines in the mafic volcanic sample, and concentrations of aluminum and arsenic were slightly elevated compared to CCME aquatic life guidelines in the greywacke sample. Potential for release of trace concentrations of these elements is consistent with the mineralogy and elemental composition of the samples.

The number of samples is too few to determine the potential variability in concentrations within or between each of these rock types. However, once further information on the underground development plans is available, these data could be used in scoping level calculations to provide an initial indication of the potential magnitude of contaminant loading. If those calculations indicate potential for impacts, further testing may be warranted.

## 5 Conclusions and Recommendations

Test results indicate that the majority of the waste rock that would be produced from the proposed exploration decline would be non-acid generating. A few samples (<10%) from the hanging wall of the deposit were classified as acid generating or potentially acid generating. However, they contain significant amounts of neutralization potential. Provided that these isolated intervals of material are well distributed in the waste dump, ARD is unlikely to occur. Monitoring of the blasted rock during excavation of the decline may be required to ensure that any potentially acid generating rock is identified and managed appropriately.

Data from several of the Iron Formation samples had NP/AP ratios in the range of 1 to 3, indicating this material should be classified as potentially acid generating. This material contains sufficient NP that there is likely to be a significant lag time to acid generation. However, to ensure long-term stability of this material, consideration should be given to encapsulating it within the center of the waste rock pile where can be frozen, or to return it to the underground workings where it will eventually become flooded.

The iron formation rock contains iron oxide minerals which may become mobilized as a result of reductive dissolution. Evidence from the Ekati Diamond Mine™ indicates that reductive dissolution of iron can lead to the development of low pH conditions downstream of waste piles as the iron re-precipitates and releases hydrogen ions. Care should be taken to avoid placing this material or any rock that contains significant quantities of iron sulphides directly on organic soils or plant matter.

Elemental analyses indicate there is some potential for release of arsenic and other trace elements from the rock. Aluminum arsenic, copper and iron were slightly soluble in two of three leach extraction tests. The leach extraction results can be used in conjunction with information on the

amount of waste rock, the hydrology, and the expected configuration of the dump to calculate the potential magnitude of contaminant loading from this material.

Depending on the timing of the permit application, it may be worth considering initiating a small number of kinetic tests. These would be useful for future environmental assessment work, and would provide the information needed to estimate water quality from the development waste rock dump. At this stage in the project, one sample from each of the main rock units should be considered.

If you have any questions, please contact the undersigned.

Yours truly,

Kelly Sexsmith, P.Geo
Senior Environmental Geochemist

Notes: Sulphide Sulphur method not specified.
AP is calculated from the sulphide sulphur
NP was completed using the Standard Sobek method
* NP, CO3-NP, AP, and NNP are presented in units of kg CaCO3 eq/tonne
** It is noted that tailings will not be produced during development of the exploration decline.

Notes:

AP = Acid potential in tonnes CaCO3 equivalent per 1000 tonnes of material. AP is determined from calculated sulphide sulphur content: S(T) - S(SO4).
NP = Neutralization potential in tonnes CaCO3 equivalent per 1000 tonnes of material.
NET NP = NP - AP
Carbonate NP is calculated from CO2 originating from carbonates and is expressed in kg CaCO3/tonne.

**FROM** Albert Stoffers, Jennifer Cole, Valerie Bertrand **EMAIL** jcole@golder.com

**GEOCHEMISTRY PROGRAM SITE VISIT REPORT: SUMMARY OF SAMPLING AND FIELD TEST CONSTRUCTION ACTIVITIES, MELIADINE PROJECT, NUNAVUT**

This technical memorandum summarizes field activities completed during a site visit to the Agnico-Eagle Mines Ltd. (AEM) Meliadine Project by Golder geochemists Jennifer Cole and Albert Stoffers from July 6-17, 2011. A site orientation was provided immediately upon Golder's arrival by on-site AEM staff. The main tasks to be completed during the site visit included:

- Collecting core samples representing waste rock and ore from the Discovery, F-Zone, Pump, Tiriganiaq, Wesmeg, and Wolf deposits for static and kinetic testing;
- Constructing and sampling 4 field barrels, including 2 containing waste rock and 2 containing ore with charge material obtained from the existing operations pad; and,
- Installing and sampling 2 drive point piezometers downstream of the operations pad to replace those installed in 2010 and destroyed during the expansion of the operations pad this past winter. This task was out of the original scope of work for the site visit.

These tasks are described in detail below. The field program was completed to address anticipated requirements for baseline studies in support of the Environmental Impact Statement and of the Tailings and Waste Rock Management Studies, as outlined in our proposal (Golder, 2011).

## 1.0 WASTE ROCK AND ORE SAMPLE COLLECTION

The following information was reviewed prior to the site visit in order to select appropriate sample intervals:

- Geology of the deposits;
- Previous reports on mine waste geochemistry (Golder, 2010);
- Up-to-date tonnage estimates of waste rock per deposit per rock type (10000 tpd Max pits) (*Lithology_proportion_pit 10000tpd.xlsx* dated June 13, 2011, D. Duquette pers. comm.; see attached);

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

- Geological sections for each deposit including the 10000 tpd pit outlines provided by AEM; and,
- Down-hole data including depth, rock type and gold assay results.

Sample intervals were selected to achieve a good spatial distribution throughout the deposits, and specifically targeting areas of open pit expansion not previously characterized for the Tiriganiaq, F Zone, and Discovery deposits. Sample proportions were also targeted per deposit and rock type to be consistent with the expected waste rock tonnages to be generated from each deposit per rock type (as per *Lithology_proportion_pit 10000tpd.xlsx* dated June 13, 2011, D. Duquette pers. comm.). This information is included in Attachment A.

Table 1 summarizes the total samples collected from each deposit and Table 2 compares the total estimated tonnage of waste with the proportion of samples from each rock type. A breakdown of samples collected per deposit and per rock type is provided in Attachment B, and a list detailing each sample collected is provided in Attachment C. Photographs of typical rock type intervals are included in Attachment D.

It is understood that the undefined (UO) unit in the waste rock is a stratigraphic unit composed of greywackes and banded iron formation, similar to the Upper Oxide Formation within the Tiriganiaq Formation. It is approximately composed of 80% greywacke and 20% iron formation (S. Patry, pers. comm. June 28, 2011).

1- *Lithology_proportion_pit 10000tpd.xlsx* dated June 13, 2011, D. Duquette pers. comm.

Each waste rock and ore sample was described in terms of rock type, sulphide and carbonate mineralogy, metamorphism, alteration, and staining associated with sulphide mineral oxidation. Each sample consisted of a composite of 3 to 5 kilograms of core (whole or split) collected from previously drilled (pre-2011) diamond drill core over an interval of 5 to 12 metres. The length of the sample interval was intended to circumvent the effect of mineral clusters, and particularly sulphide minerals, which may not be representative of the bulk rock mass along the targeted interval.

All sampled core was located at the main camp with the exception of Discovery core, which was located at the Discovery camp. A total of 8 Wesmeg sample intervals were selected from 2011 holes to augment those intervals available in older holes and to meet the targeted sample count.

The collected samples have been shipped to SGS Canada Inc. of Lakefield, Ontario for analysis. Samples of waste rock and ore (including field test composites described below) will be subjected to the following suite of static tests aimed at defining and documenting the propensity of the material to generate acid drainage and to leach metals to the receiving environment:

- Major and trace element analysis on solids: whole rock analysis by X-ray fusion and trace element analysis by triple acid digestion followed by ICP-MS analysis;
- Acid generation (ARD) potential using the modified Sobek method of Acid-Base Accounting (ABA) and carbonate neutralisation potential assessment. These analyses include: paste pH, total sulphur and sulphate sulphur, total carbon and carbonate, and bulk neutralization potential;
- Short-term leaching test using the Shake Flask Extraction (SFE) neutral pH water leaching method, with leachate analysis by ICP-MS; and,
- Net Acid Generation (NAG) test pH and leachate on a subset of samples.

## 2.0 FIELD CELL CONSTRUCTION

Field test cells were constructed using 50 gallon drums and crushed rock charge material collected from the operations pad (see Attachment E for photographs). Field cells will serve to assess the effects of mixed rock, wider grain size distribution and field weathering conditions on chemical loading rates from the charge material, and results are used to extrapolate laboratory results to provide more realistic, field-specific chemical loadings to mine contact water.

The four test cells include:

- WR 1 and WR 2: two field cells were constructed using a composite of waste rock material collected from 12 test pits completed in the operations pad to a depth of 1-2 meters using a mechanical shovel. A composite sample was collected from each test pit for static testing and 50 kg (110 pounds) of material was collected from each test pit as charge material for the field cells, resulting in 300 kg of charge material per field cell. Sample collection targeted material from throughout the test pit after scraping off surface material. A composite sample representative of the field cell charge material will be generated for static testing using equal proportions of prepped material from each of the 12 composite samples;

- Lode 1000 ore: collected from a combined high and low grade ore stockpile at 12 discreet locations around the base and top surface of the stockpile using a shovel. A total of 25 kg (55 pounds) was collected from each discreet location to generate a composite, from which one sample was collected for static testing. It is understood that the high and low grade stockpiles were combined into one pile by AEM. The total mass of the composite sample used as charge material in the field test cell was 300 kg; and,
- Lode 1100 ore: collected from the high grade ore stockpile at 12 discreet locations around the base and top surface of the stockpile using a shovel. A total of 25 kg (55 pounds) was collected from each discreet location to generate a composite, from which one sample was collected for static testing. The total mass of the composite sample used as charge material in the field test cell was 300 kg.

A photo documentary of the cell construction is included in Attachment E and the set up is shown on Photograph 1.

*Photograph 1: Final Set up of Field Test Cells Located Southeast of the Portal*

After construction of the field cells, an “initial wash” was completed (Cycle 0) using 5 litres of lake water (termed “leach water”) for each waste rock cell, and 10 litres for each ore cell due to their higher proportion of fine material, and consequent higher water retention. Leach water was collected from the nearby lake in the background of Photo 1 using a clean plastic bucket. Water was added to the cells on 14 July 2011 and allowed to drain into a receptacle prior to sampling on 16 July 2011. A high proportion of fine material in the Lode 1000 test cell had to be removed by extensive washing to avoid creating low permeability barriers in the test cell, which would cause future drainage problems. Cycle 0 water samples were collected and submitted to Maxxam Laboratory in Ottawa for analysis of general chemistry, dissolved metals, and nutrients.

Cycle 1 was conducted by adding 5 L of leach water to the waste rock cells and 8 L of leach water to the ore cells on 16 July 2011 after collection and disposal of Cycle 0 water. The cells were allowed to drain overnight and samples were collected on 17 July 2011. A total of 1.75 L of water was collected for analytical testing per field cell, with the remaining volume of Cycle 1 water recorded for mass loading calculations.

AEM staff geologist (Morgan Hjorth) was instructed on the cell leaching and sampling protocol. Subsequent leaching cycles will be performed and leachate samples will be collected by Golder or AEM staff, depending on availability. A detailed sampling protocol will be provided under separate cover.

Table 3 summarizes the field parameters and observations for Cycle 0 and Cycle 1.

**Table 3: Summary of Field Cell Leachate Observations**

| Sample ID | Cycle | pH | Conductivity | Temperature | Observations |
|---|---|---|---|---|---|
| WR 1 | Cycle 0 | 8.02 | 692 | 18.2 | high suspended solids |
| | Cycle 1 | 7.13 | 768 | 12.0 | leachate remaining[1]= 0.5L |
| WR 2 | Cycle 0 | 8.00 | 733 | 18.8 | high suspended solids |
| | Cycle 1 | 7.50 | 709 | 12.5 | leachate remaining[1]= 0L |
| Lode 1100 | Cycle 0 | 7.91 | 1140 | 18.8 | high suspended solids |
| | Cycle 1 | 7.81 | 1332 | 13.1 | leachate remaining[1]= 4.5L |
| Lode 1000 | Cycle 0 | 7.60 | 2783 | 18.7 | high suspended solids |
| | Cycle 1 | 7.77 | >4000 | 11.5 | leachate remaining[1]= 3.5L |

1- volume of leachate water remaining after collection of 1.75 L for analytical testing

A total of 9 water samples were collected during the site visit, including the following:

- Cycle 0 and Cycle 1 for each test cell (8 samples); and,
- Lake water used for leaching (1 sample).

The samples were stored in a cooler in a fridge until transportation by Golder to Maxxam Laboratory in Ottawa. Water samples are being analyzed for the following parameters:

- General chemistry (pH, conductivity, total alkalinity (as CaCO3), chloride, sulphate);
- Nutrients (ammonia (as nitrogen), nitrate, nitrite, total phosphorus (colorimetric)); and,
- Dissolved metals and total metals (aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, lithium, magnesium, manganese, molybdenum, nickel, phosphorus, potassium, selenium, silicon, silver, sodium, strontium, tellurium, thallium, thorium, tin, titanium, tungsten, uranium, vanadium, zinc, zirconium).

## 3.0 DRIVE POINT PIEZOMETER INSTALLATION

Two drive point piezometers were installed in 2010 on the southwest edge of the operations pad and within the primary containment. These piezometers were destroyed when the pad was expanded over the last winter. Approval for installation of 2 additional drive point piezometers on the south side of the road was received while the Golder field staff were on site, but the equipment was not received in time for installation and sample collection. Two locations were staked and GPS coordinates were measured for Golder staff to install and sample the shallow groundwater from these monitors at a later date (Attachment F).

**Table 4: Proposed Drive Point Piezometer Locations**

| Location | Northing | Easting |
|---|---|---|
| DP11-01 | 6988942 | 540009 |
| DP11-02 | 6988967 | 540026 |

Samples will be shipped by Golder staff to Maxxam Laboratory in Ottawa for the same suite of analytical parameters as the other water samples.

## 4.0 CLOSURE

Golder thanks the AEM staff and their subcontractors at Meliadine camp for their welcome and the valuable assistance provided during the site visit.

We trust this report meets your current requirements. Please contact us should you have any questions or comments.

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**LR Report :** **CA10221-AUG09**

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**Modified ABA (Price 1997)**

**LR Report :** **CA10178-DEC09**

*NP (Neutralization Potential)

$$= \frac{50 \times (\text{N of HCL} \times \text{Total HCL added} - \text{N NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**LR Report :** **CA10282-JUL09**

*NP (Neutralization Potential)

$$= \frac{50 \times (\text{N of HCL} \times \text{Total HCL added} - \text{N NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**LR Report :** CA11183-AUG09

*NP (Neutralization Potential)

$$= \frac{50 \times (\text{N of HCL} \times \text{Total HCL added} - \text{N NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

$$= \frac{50 \times (\text{N of HCL} \times \text{Total HCL added} - \text{N NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**LR Report : CA10278-JUL09**

*NP (Neutralization Potential)

$$= \frac{50 \times (\text{N of HCL} \times \text{Total HCL added} - \text{N NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

Carb-NP = (% Total C)x(100.09/12.01)x(10)
*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

Lakefield - Ontario - KOL 2HO
Phone: 705-652-2000 FAX: 705-652-6365

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

Carb-NP = (% Total C)x(100.09/12.01)x(10)
*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**LR Report : CA11285-AUG09**

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)

**LR Report :** **CA11285-AUG09**

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.01 will be calculated using a 0.01 value.

Sulphur analysis performed following BC ARD Guidelines (Price 1997)
