APPENDIX B: IMPACT OF FRESHWATER WITHDRAWALS FOR MINE OPERATION AND MINE CLOSURE SCENARIOS ON LAKE VOLUME, LAKE LEVEL AND FLOW

TECHNICAL MEMO

To:	Agnico Eagle
Att.:	Lisa Ramilo
Cc:	Sam Gordon
From:	Patrick Delaney and Michael Yu
DHI ref.:	42804619-03
Project:	Meliadine Lake Watershed Hydrology Modelling
Date:	October 12, 2026
Subject:	Impact of Freshwater Withdrawals for Mine Operation and Mine Closure Scenarios on Lake Volume, Lake Level and Outflow

Key Findings

This memorandum presents additional analysis evaluating how proposed freshwater withdrawals affect Meliadine Lake volume beneath ice cover, lake water level, and lake outflow under Baseline; Mine Operation; and Mine Closure scenarios. Results are compared to DFO protocols and frameworks to evaluate potential effects on fish and fish habitat.

The updated HEC-HMS model improves winter lake-level representation by applying separate outflow rating curves for ice-free and ice-cover conditions.

Under the Mine Operation scenario (2026-2036), the proposed freshwater withdrawals have negligible effects on the monthly lake volume (including under ice lake volumes), water level and discharge.

Under the Mine Closure Scenario (2037-2043), the proposed freshwater withdrawals have negligible effects on the monthly lake volume (including under ice lake volumes) and water level but result in average monthly flow reductions greater than 10% in the outlets for select months (August, September, October). However, these effects are not predicted to occur during a period where instantaneous flows are less than 30% of the Mean Annual Discharge.

Background

Agnico Eagle contracted DHI Water & Environment, Inc. (DHI) to provide professional services in support of the Meliadine Water Licence Amendment. The scope of work focused on hydrological modelling to characterize runoff to Meliadine Lake under historical and future climate conditions. The project objectives were to:

- Develop a hydrology model of the entire Meliadine Lake watershed
- Calibrate and validate this model against historical data
- Quantify runoff entering Meliadine Lake from its watershed over a future 16-year period (2026–2041) using a continuous historical climate record.

- Assess the potential effects of freshwater withdrawals on Meliadine Lake water levels under future mine operations and mine closure conditions.

These objectives were completed and documented in a report (DHI, 2026a) and a supplementary technical memo (DHI, 2026b).

The Department of Fisheries and Oceans reviewed the freshwater withdrawal assessment and requested additional analysis of the potential effects of freshwater withdrawals on lake volume beneath ice cover and on outflow from Meliadine Lake.

The existing HEC-HMS model applies the same outflow rating curves during ice-free and ice-cover conditions. However, Meliadine Lake water level measurements suggest that the rating relationship is likely affected by ice cover, resulting in reduced outflow during winter. Potential model options were therefore explored to provide a more realistic representation of reduced outflow during ice-cover conditions.

The updated model was used to evaluate the freshwater withdrawal scenarios listed below. For each scenario, monthly lake level, lake outflow, total lake volume, and available liquid water volume beneath ice cover were summarized and compared against the applicable baseline condition.

1. Baseline: no mine operation or closure withdrawal.
2. Mine Operation: freshwater withdrawal of 1,110,296 m^3/yr using variable monthly extraction rates based on historical water-use records (from 2026-2036).
3. Mine Closure Scenario: freshwater withdrawal of 8,700,000 m^3/yr using a constant daily extraction rate of 80,556 m3/day from June 15 to September 30 (from 2037 to 2043).

The methodology and model results are summarized in the following sections.

1 Model Update

1.1 Applying Different Rating Curves for Ice-free and Ice-cover Conditions

To allow for different outflow rating curves at different seasons, the reservoir representing Meliadine Lake was updated to use the Rule-based Operations method. Outflows through the Main and West outlets were represented as General Outlets. Minimum and maximum discharge rating curves were used to define the lower bounds of the outflow using ice cover conditions, and the upper bounds of the outflow during ice-free conditions. For a given lake level, the outlet discharge was linearly interpolated between the corresponding discharge values from the minimum and maximum rating curves. When the outlets are fully open, the maximum rating curve is applied; when the outlets are closed, the minimum rating curve is applied. The calibrated minimum (ice cover) rating curves for the Main outlet and the West outlet are shown in Figure 1 with a comparison to the maximum rating curves for ice free conditions. Modelled lake levels from the original single-rating-curve model and the updated two-rating-curve model are compared with measured lake levels in Figure 2. The comparisons are made using climate data from the onsite Camp station and the Rankin Airport station. The modelled lake levels from the updated two-rating-curve model shows a substantially improved match with the measured lake levels for the period from January through May. As a result, the updated model was used for the subsequent analysis of freshwater withdrawals during Mine Operation and Mine Closure periods.

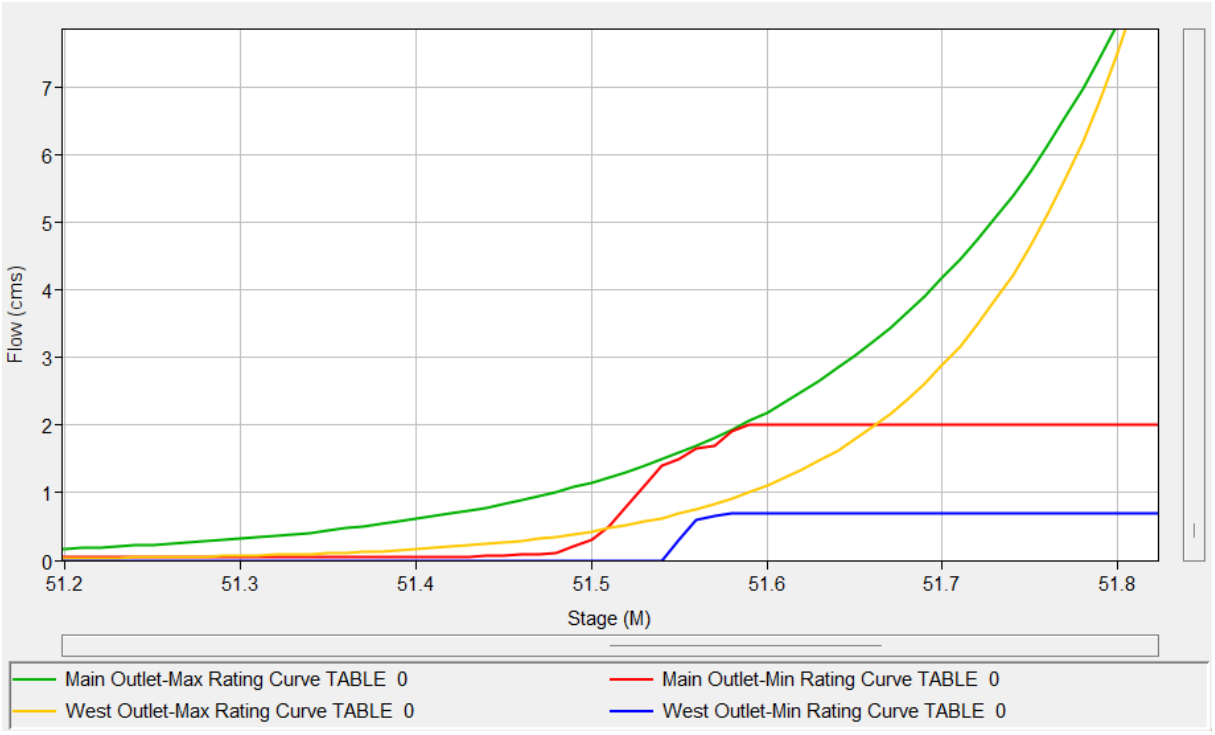

Figure 1 Outflow rating curves for ice-free and ice-cover conditions

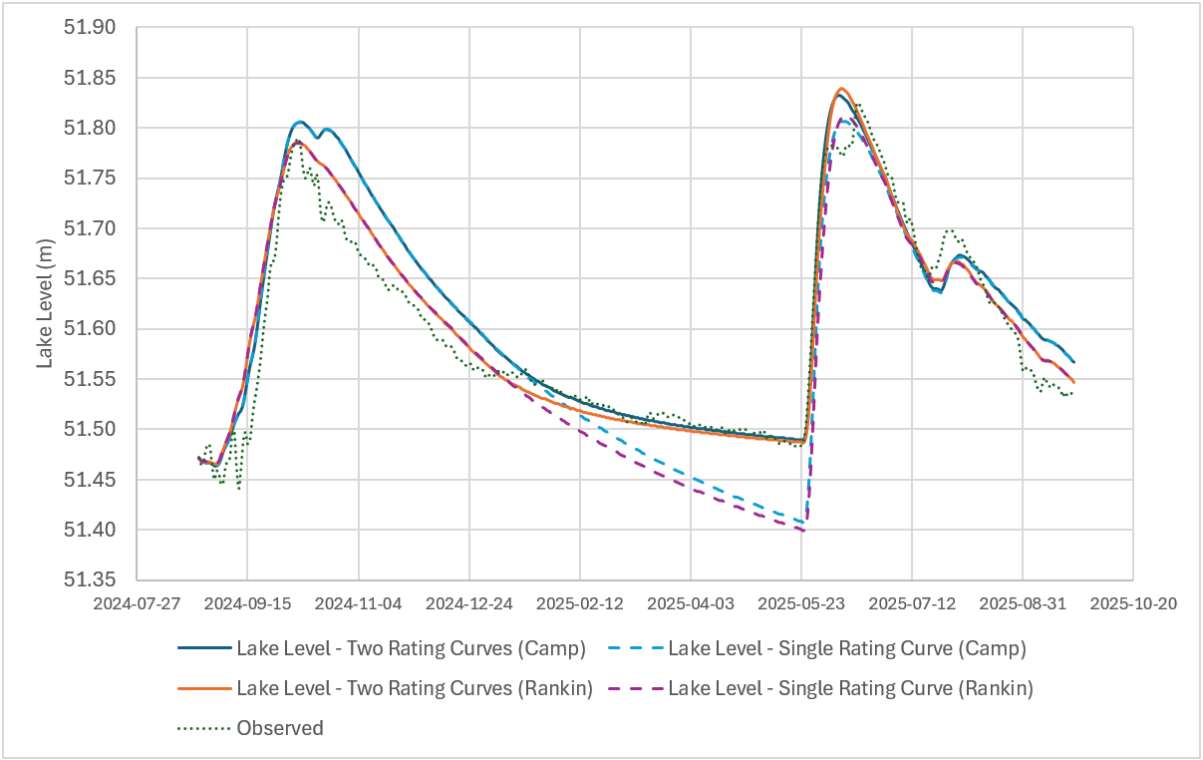

Figure 2 Modelled and measured lake level using rainfall data from both the onsite Camp climate station and the Rankin Airport climate station

1.2 Representing Freshwater Withdrawal

As described in the report (DHI, 2026a), freshwater withdrawal was originally represented as an additional release using a time-series of withdrawal rates. However, additional releases are not supported by the Rule-based Operations method, so the updated model needed to be adapted to account for freshwater withdrawal. Following a review of available options, evaporation was identified as the most suitable option to use for representing water loss from the lake. As a results, freshwater withdrawals were incorporated into the monthly evaporation rates used in the model. The withdrawal volumes were converted to equivalent depths using a representative lake surface area, and these depths were then summarized as monthly averages, and added to the monthly evaporation input. The modelled monthly lake evaporation values for all scenarios are listed in Table 1. In this table, the Baseline scenarios including only evaporation, while the Mine Operation and Mine Closure scenarios include the freshwater withdrawal as part of the total evaporation (expressed in units of mm depth).

Key assumptions used in this assessment include the representative lake surface area used to convert withdrawal volumes to equivalent evaporation depths, the monthly averaging of withdrawal-equivalent evaporation, the use of separate ice-free and ice-cover outflow rating curves, and the ice-volume assumptions described in Section 2.1.

Table 1 Monthly lake evaporation including modelled freshwater withdrawal

1.3 Ice Volume Calculations

To evaluate the effect of freshwater withdrawals on liquid water available beneath the ice cover, the model results were post-processed to estimate the portion of total lake storage present as ice during each month. The hydrologic model calculates lake level and total lake storage, but it does not explicitly simulate the formation, growth, or melt of lake ice. Therefore, an independent ice-volume calculation was applied after the model simulations were completed.

For this assessment, ice formation was assumed to begin on November 1, increase linearly to a maximum thickness of 2 m on March 30, and then decrease linearly to 0 m by May 30. Daily ice thickness values were estimated by linear interpolation between these dates.

Total lake volume was calculated from the modelled lake level using the lake stage-storage relationship. The estimated ice volume was then calculated from the assumed ice thickness and the corresponding lake surface area, accounting for the lower density of ice relative to liquid water. The remaining storage was interpreted as liquid water volume beneath the ice. In other words, the total modelled lake storage was separated into two components: water stored as ice cover and water remaining as liquid beneath the ice.

Figure 4 shows the average monthly total water volume and the corresponding estimated liquid water volume for the Baseline (no mine operations) scenario from 2026-2036. The difference between these two values represents the portion of total lake storage estimated to be present as ice cover during winter and spring.

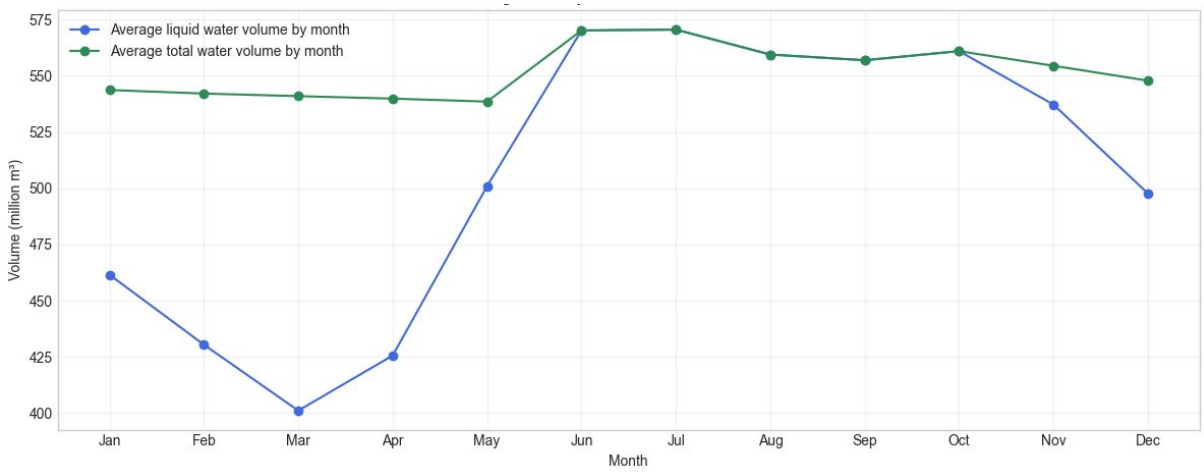

Figure 3 Average monthly lake volumes – Baseline (2026-2036)

2 Model Result Summary

The updated model was run for the scenarios described in Table 2.

Table 2 Model scenarios

Scenario	Freshwater Withdrawal (m^3/yr)	Freshwater Withdrawal Period	Simulation Period	Climate Scenario
Baseline (2026-2036)	0	NA	2026-2036	RCP 8.5
Baseline (2037-2043)	0	NA	2037-2043	RCP 8.5
Mine Operation	1,110,296	All Year	2026-2036	RCP 8.5
Mine Closure	8,700,000	June 15- Sept 30	2037-2043	RCP 8.5

The analysis scenarios were all run using the future climate data from the RCP 8.5 climate scenario. This climate scenario was selected because it represents the potential worst-case scenario for reductions in annual precipitation. That being said, the assumptions about ice formation and thickness on the lake were not adjusted for climate change considerations, nor was the minimum rating curve or the timing of the transition from maximum (ice free) to minimum (ice cover) conditions.

Evaluation Criteria: The following sections compare the Mine Operation and Mine Closure scenarios with their corresponding Baseline scenarios. The assessment focuses on annual average monthly lake volume, water level and outflow.

Primary screening thresholds: Potential effects of freshwater withdrawals were evaluated against the following screening criteria: less than a 10% change in liquid water (under ice) volume (Fisheries and Oceans Canada, 2010), and less than a 10% decrease in outflow at each outlet (Fisheries and Oceans Canada, 2013).

Secondary outflow criterion: Where the monthly outflow reduction exceeds 10% relative to the Baseline scenario, a secondary criterion was applied: the annual average monthly outflow for the Mine Operation or Mine Closure scenario should remain greater than 30% of the mean annual outflow for the period during which the scenario is assessed (e.g. 2026-2036 for the Mine Operations scenario, and 2037-2043 for the Mine Closure scenario) (Fisheries and Oceans Canada, 2013).

Need for further assessment: If the monthly outflow reduction exceeds 10% relative to baseline ***and*** the outflow in that month is less than 30% of mean annual discharge, a more detailed assessment is recommended to evaluate potential effects on ecosystem functions. Such an assessment is outside the current scope of this study.

Seasonal scope for outflow comparisons: For this discussion, monthly outflow comparisons are restricted to the period of June through December, when it is assumed that lake outflow is not significantly inhibited by ice-cover conditions.

2.1 Mine Operation Scenario

The mine operation scenario includes freshwater withdrawal of 1.11 million m^3/yr and effluent discharge of 0.86 million m^3/yr. The recorded monthly distributions for withdrawal and discharge from 2024 were repeated for the 2026 to 2036 simulation period (see Figure 4 below)

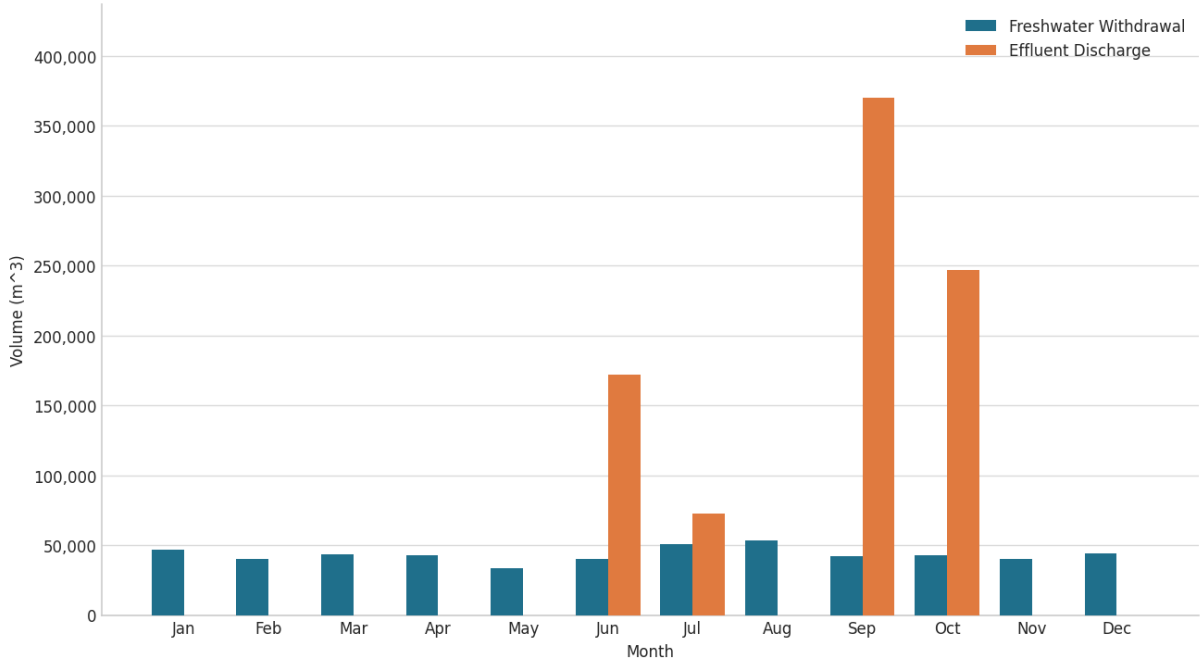

Figure 4 Monthly freshwater withdrawal and effluent discharge volume in 2024

The annual average monthly lake volume, water level, and outflow are summarized in Table 3, Table 4, Table 5 and Table 6, respectively. These results indicate that operational withdrawals have a negligible effect on lake storage, water level and outflows at the monthly scale.

Table 3 Baseline results are also included in these tables, with both absolute and relative changes calculated for comparison. The maximum % decrease in lake volume occurs in May with a 0.061% reduction in absolute volume (including ice cover) and 0.062% reduction in the liquid (under ice) volume. On an annual average basis, stored water volume decreases by 0.018%.

The average annual outflow from the Main Outlet into Meliadine River decreases by 2.1% with the largest monthly decrease of 0.6% occurring in June.

The average annual outflow from the West Outlet decreases by 0.5% with the largest monthly decrease of 0.8% occurring in June.

These results indicate that operational withdrawals have a negligible effect on lake storage, water level and outflows at the monthly scale.

Table 3 Lake volume comparison – Mine Operational Scenario (2026-2036)

Month	Baseline (m^3)	Mine Operational (m^3)	Absolute Change (m^3)	Relative Change (%)	Relative Change Under Ice (%)

2.2 Mine Closure Scenario – Open-Water Withdrawal

Mine Closure Scenario includes freshwater withdrawal of 8.7 million m^3/yr, distributed evenly from June 15 to September 30. The annual average monthly lake volume, water level, and outflow discharge rate are summarized in Table 7, Table 8, Table 9 and Table 10, respectively.

The maximum decrease in lake volume occurs in September with a reduction of 0.562% of the absolute volume of the lake due to the lower outflow during this month. On an annual average basis, stored water volume decreases by 0.224%.

The average annual outflow from the Main Outlet (Meliadine River) decreases by 6.3% with the largest monthly decrease (during the free flow condition from June through December) of 12.7%, 16.1% and 10.2% occurring in August, September and October, respectively.

Since the decrease in outflow from the Main Outlet (Meliadine River) in August, September and October exceeds the 10% threshold, the outflow for these months must also be evaluated against the secondary criteria whereby the outflow should be greater than 30% of the mean annual discharge. For Meliadine River, the mean annual discharge for the 2037-2043 Baseline scenario is 192,247 m^3/day and 30% of the mean annual discharge is 57,674 m^3/day. The average monthly flow in August, September and October is 259,621 m^3/day, 240,248 m^3/day and 307,638 m^3/day, respectively. The average monthly flow in August through October are well above 30% of the mean annual discharge.

The average annual outflow from the West Outlet decreases by 9.6% with the largest monthly decrease (during the free flow condition from June through December) of 17.8%, 22.7% and 13.8% in August, September and October, respectively.

Since the decrease in outflow from the West Outlet in August through October exceeds the 10% threshold, the outflow for these months must also be evaluated against the secondary criteria whereby the outflow should be greater than 30% of the mean annual discharge. For the West Outflow, the mean annual discharge for the 2037-2043 Baseline scenario is 141,680 m^3/day and 30% of the mean annual discharge is 42,504 m^3/day. The average monthly flow in August, September and October is 130,493 m^3/day, 108,849 m^3/day, and 182,879 m^3/day, respectively. The average monthly flow in August through October is well above 30% of the mean annual discharge.

These results indicate that Mine Closure Scenario meets the under-ice lake volume reduction criteria for freshwater withdrawals during the mine closure period, with some exceedances in criteria for reductions in average monthly flows.

3 Summary and Conclusion

The current modelling exercise was used to evaluate potential project related effects on Meliadine Lake hydrologic system during operations and closure against the DFO *Protocol for Winter Withdrawals from Ice-Covered Waterbodies in the Northwest Territories and Nunavut (*2010*),* and the *Framework for Assessing Ecological Flow Requirements to Support Fisheries in Canada (*2013*).*

The updated model provides separate rating curves for ice-free and ice-cover conditions.

Under the Mine Operation scenario, the proposed freshwater withdrawals have negligible effects on the monthly lake volume (including under ice lake volumes), water level and discharge.

Under the Mine Closure Scenario (2037-2043), the proposed freshwater withdrawals have negligible effects on the monthly lake volume (including under ice lake volumes) and water level but result in monthly average flow reductions greater than 10% in the outlets for select months (August, September, October). However, these effects are not predicted to occur during a period where instantaneous flows are less than 30% of the Mean Annual Discharge.

The closure withdrawal volumes, timing, and duration remain subject to refinement as closure planning advances. Once the proposed closure water requirements are better defined, the potential effects will be reassessed through the interim and final closure planning process.
