AGNICO EAGLE

MELIADINE GOLD PROJECT

2018 Annual Report

Prepared for:
Nunavut Water Board
Nunavut Impact Review Board
Fisheries and Oceans Canada
Crown-Indigenous Relations and Northern Affairs Canada
Kivalliq Inuit Association

Prepared by:
Agnico Eagle Mines Limited – Meliadine Division

TABLE OF CONTENTS

SECTION 1. INTRODUCTION....1

SECTION 2. SUMMARY OF ACTIVITIES....2

2.1 2018 Activities....2
2.1.1 Exploration activities....2
2.1.2 Construction activities....3
2.1.3 Mining Activities....3
2.2 2019 Mine WORK Plan....8
2.3 Quarries....8

SECTION 3. WATER MANAGEMENT ACTIVITIES....9

3.1 Water Movement....9
3.1.1 Fresh water obtained from Meliadine Lake....9
3.1.2 Fresh water obtained from Meliadine River....10
3.1.3 Mine Water pumped from underground....10
3.1.4 Water discharged from CP-1 to Meliadine Lake....11
3.2 Water Balance Water Quality Model Reporting Summary....11
3.3 Additional Information....13

SECTION 4. WASTE ROCK MANAGEMENT ACTIVITIES....14

4.1 Geotechnical monitoring....14
4.1.1 Thermistors in the vicinity of the project....16
4.1.2 Thermistors in the P-area....16
4.1.3 Thermistors at D-CP1....17
4.1.4 Thermistors at D-CP5....18
4.2 Geochemical Monitoring....19
4.2.1 Mine development waste rock....20
4.2.2 Quarry Material....21
4.3 Waste Rock Volume....22
4.4 Tailings Storage Facility....23
4.4.1 Tailings Storage Facility Capacity....23
4.4.2 Tailings Freezeback and Capping Thickness....23

SECTION 5. WASTE MANAGEMENT ACTIVITIES....24

5.1 Landfill Monitoring, Waste Rock Storage Facility....24
5.2 General Waste Disposal Activity....24
5.3 Incinerator....25
5.4 Additional Information....27

SECTION 6. SPILL MANAGEMENT....28

SECTION 7. MONITORING....35

7.1 Aquatic ecosystem monitoring program (aemp) 35
7.1.1 Peninsula Lakes Summary and Conclusions 36
7.1.2 Meliadine Lake Summary 36
7.1.3 Meliadine Lake Conclusions 37
7.2 MDMER and EEM sampling 38
7.3 Mine site water quality 40
7.3.1 *Licensed Water Sampling Stations* 40
7.3.1.1 MEL-1 Raw water supply intake at Meliadine Lake 40
7.3.1.2 MEL-2 Raw water supply intake at Pump, A8 or other Lakes 40
7.3.1.3 MEL-5 Bermed Fuel Containment Facilities 40
7.3.1.4 MEL-6 Landfarm Treatment Facility 40
7.3.1.5 MEL-7 Effluent from Exploration camp STP 40
7.3.1.6 MEL-8 Point of discharge or runoff from the Non-Hazardous Waste Landfill 40
7.3.1.7 MEL-SR-1-TBD 40
7.3.1.8 MEL-11 Water Intake 41
7.3.1.9 MEL-12 Water treatment plant (Pre-treatment) 41
7.3.1.1 MEL-03-01 Reference area in Meliadine Lake (MDMER reference station) 42
7.3.1.2 MEL-13 Mixing Zone in Meliadine Lake (MDMER exposure station) 42
7.3.1.3 MEL-14 Water treatment plant (Post-treatment) 42
7.3.1.4 MEL-15 Local Lake E3 44
7.3.1.5 MEL-16 Local Lake G2 45
7.3.1.6 MEL-17 Local Pond H1 45
7.3.1.7 MEL-18 Local Lake B5 45
7.3.1.8 MEL-19 CP-2 45
7.3.1.9 MEL-20 CP-3 45
7.3.1.10 MEL-21 CP-4 45
7.3.1.11 MEL-22 CP-5 45
7.3.1.12 MEL-23 CP-6 46
7.3.1.13 MEL-24 Seepage from the landfill 46
7.3.1.14 MEL-25 Secondary Containment at the Itivia Fuel Storage Facility 46
7.3.2 Underground sampling 47
7.3.3 QAQC Sampling 47
7.4 Seepage 48
7.5 Visual AWAR Water Quality Monitoring 49
7.6 Blast Monitoring 49
7.7 Noise monitoring 49
7.8 Air 51
7.8.1 Air Quality monitoring 51
7.8.2 Greenhouse Gas Emissions 52
7.8.3 Climate 52
7.9 Wildlife monitoring 53
7.9.1 TEMMP 53
7.9.2 Marine Environment 56
7.10 Archaeology 56
7.11 Vegetation 56

SECTION 8. CLOSURE 58

8.1 Progressive Reclamation 58
8.1.1 Mine Site 58
8.1.2 AWAR 58
8.1.3 Quarries 58

8.2 Reclamation Costs 58

SECTION 9. STUDIES/REVISIONS/MODIFICATIONS 60

9.1 Summary of Studies 60
9.2 Summary of Revisions 60
9.3 Modifications 61

SECTION 10. OTHERS 62

10.1 Active Permits 62
10.2 Inspections 62
10.3 AWAR 64
10.4 Maritime transportation 66

SECTION 11. PUBLIC CONSULTATION 67

11.1 Community Meetings in Chesterfield Inlet 67
11.2 Community Meetings in Rankin Inlet 67
11.3 Meetings with Rankin KHTO 68
11.4 Community Liaison Committee Meetings 68
11.5 Elders 68
11.6 Site Tours for Rankin Inlet Residents 68
11.7 Community Engagement Initiatives 69
11.8 Community Coordinators Program 69
11.9 Communication 69

SECTION 12. SOCIO ECONOMIC 70

12.1 Workforce 70
12.1.1 Employment Demographics for Nunavut Based Employees 71
12.1.2 Employee retention 72
12.1.3 Summer Student Employment Program 73
12.2 Training 73
12.2.1 Pre-employment training 73
12.2.2 Work Readiness Training Program 74
12.2.3 Mandatory Training (Site Readiness) 74
12.2.4 Training Hours 74
12.3 Training Programs 75
12.3.1 E-learning 75
12.3.2 Cross-Cultural 76
12.3.3 Career Paths 76
12.3.4 Apprenticeship Program 76
12.4 General Socio-Economic Provisions 77
12.4.1 Housing and Home Ownership 77
12.4.2 Labour Force 77
12.4.3 Training and Development 77

LIST OF TABLES

Environmental Superintendent

SECTION 1. INTRODUCTION

As required by water license 2AM-MEL1631 Part B Item 2 The Licensee shall file an annual report with the Board no later than March 31st in the year following the calendar year being reported. The annual report shall be developed in accordance with Schedule B.

And

As required by water license 2BB-MEL-1424 Part B Item 6 The Licensee shall file an Annual Report on the Appurtenant Undertaking with the Board no later than March 31st of the year following the calendar year being reported,

The Meliadine Gold Project operated by Agnico Eagle Mines Limited - Meliadine Division (Agnico Eagle) is located approximately 25 kilometres (km) north of Rankin Inlet, and 80 km southwest of Chesterfield Inlet in the Kivalliq Region of Nunavut. Situated on the western shore of Hudson's Bay, the Project site is located on a peninsula between the east, south, and west basins of Meliadine Lake (63°1'23.8''N, 92°13'6.42''W), on Inuit owned land. The project components include the 28 km All Weather Access Road (AWAR) between Rankin Inlet and Meliadine, the Itivia fuel farm and laydown area, and the mine site.

These various components and activities associated with the project require a number of different authorizations, leases and permits from regulatory agencies including the Nunavut Water Board (NWB), Environment and Climate Change Canada (ECCC), Metal and Diamond Mining Effluent Regulations (MDMER); Department of Fisheries and Oceans Canada (DFO), Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC); Kivalliq Inuit Association (KIA) and the Nunavut Impact Review Board (NIRB).

This report is written to address all of the 2018 annual reporting requirements of the project under these authorizations:

- NWB Type A water license 2AM-MEL1631;
- NWB Type B Water License 2BB-MEL1424;
- NIRB Project Certificate No. 6;
- KIA Permit KVCA07Q08;
- KIA Permit KVCA11Q01;
- KIA Production Lease KVPL11D01; and
- The Meliadine IIBA:

Reporting requirements for the MDMER have been submitted directly to ECCC; results are presented herein to comply with the NWB Type A Water License.

SECTION 2. SUMMARY OF ACTIVITIES

2.1 2018 ACTIVITIES

2.1.1 Exploration activities

As required by water license 2BB-MEL-1424 Part B Item 6i: A summary of drilling/trenching activities and progressive reclamation of drill/trench sites;

No trenches were dug in 2018 under this water licence and 19 holes were drilled. The contractor for the drilling was Sarliaq Orbit Garant and it was conducted using a diamond drill between March and August 2018. Activities included both on ice and on land drilling. Drill sites reclamation included the removal of remaining material and drill casings at each site once drilling was completed. Casings were cut at ground level when they could not be removed.

Table 2.1: Drill site locations 2018:

Hole Number	Latitude	Longitude
M18-2439	63° 1' 5.618" N	92° 17' 50.569" W
M18-2440	63° 1' 7.649" N	92° 18' 14.296" W
M18-2442	63° 2' 11.860" N	92° 20' 51.739" W
M18-2443	63° 2' 40.320" N	92° 21' 31.229" W
M18-2444	63° 2' 42.304" N	92° 21' 29.876" W
M18-2445	63° 2' 56.984" N	92° 20' 49.698" W
M18-2446	63° 2' 26.221" N	92° 20' 21.397" W
M18-2447	63° 1' 7.055" N	92° 18' 14.424" W
M18-2448	63° 1' 19.583" N	92° 18' 44.248" W
M18-2451	63° 1' 4.768" N	92° 18' 4.166" W
M18-2453	63° 2' 40.139" N	92° 21' 25.681" W
M18-2456	63° 2' 42.962" N	92° 21' 38.261" W
M18-2457	63° 2' 40.274" N	92° 21' 21.150" W
M18-2458	63° 0' 10.073" N	92° 10' 9.140" W
M18-2460	63° 0' 15.191" N	92° 11' 2.295" W
M18-2461	63° 0' 7.677" N	92° 9' 44.180" W
M18-2464	63° 0' 6.476" N	92° 9' 29.181" W
M18-2495	63° 5' 50.976" N	92° 12' 55.262" W
M18-2496	63° 5' 54.137" N	92° 13' 58.006" W

2.1.2 Construction activities

In 2018 Meliadine was in the active construction stage, with production expected to commence in 2019. Construction activities are summarized in table 2.2 below:

Table 2.2: Summary of the construction, undertaken in 2018:

Activity	Status as of Dec 31, 2018
Effluent Water Treatment Plant Diffusor into Meliadine Lake	Completed Completed
Construction of CP-1 and CP-5 Jetties (pumping stations)	Completed
Construction of permanent Landfarm	Completed
Construction of permanent Landfill	Completed
Emulsion Plant construction Commissioning and construction of the service road to the Emulsion Plant	Completed Completed
Start multi-year construction of Permanent Power Plant	Completed
Start multi-year construction of Process Plant	To be completed 2019
Start multi-year construction of Paste Plant	To be completed 2019
Start multi-year construction of multi-services building	Completed
Construction of ventilation and emergency egress East intake West exhaust	 Completed To be completed in 2019
Construction of Channels 1 and 5	Completed 2017-2018
Construction of Channels 7 and 8	To be completed in 2019
Construction of Berm 1	To be completed in 2019
Construction of Berms 2 and 3	Completed
Construction of CP-3 Pond	Completed
Construction of CP-4 Pond	To be completed 2019
Construction of CP-3 Channel	Completed
Construction of CP-4 Channel	To be completed 2019
Construction of Ore Pad 2 (OP-2)	To be completed 2019
Installation of Culverts 1, 2, 3, 4, 13, 15, 16 and 18	Completed
Installation of Culverts 7, 8, 10, 11, 14 and 19	To be completed in 2019
Construction of gazboy	Completed
Construction of Meliadine site fuel farm storage facilities	Completed
Installation of Telecommunication Tower	Completed
Portal ramp advancement	Completed
Construction of Portal 2	Completed
Construction of the Rankin Inlet Bypass road	Completed
Fuel farm and laydown area [Itivia]	Completed

2.1.3 Mining Activities

In 2018, the Meliadine Gold Project was still in the construction phase, developing the underground in preparation to operate the Tiriganiaq underground mine. A total of 688,069 tonnes of waste was

excavated, 3,134 tonnes was used as underground rockfill and the rest was used for construction purposes. A total of 39,216 tonnes of marginal and 60,846 tonnes of ore was excavated and stored at the surface ore pad 1 and 2.

Figure 2.1 2018 Meliadine Site

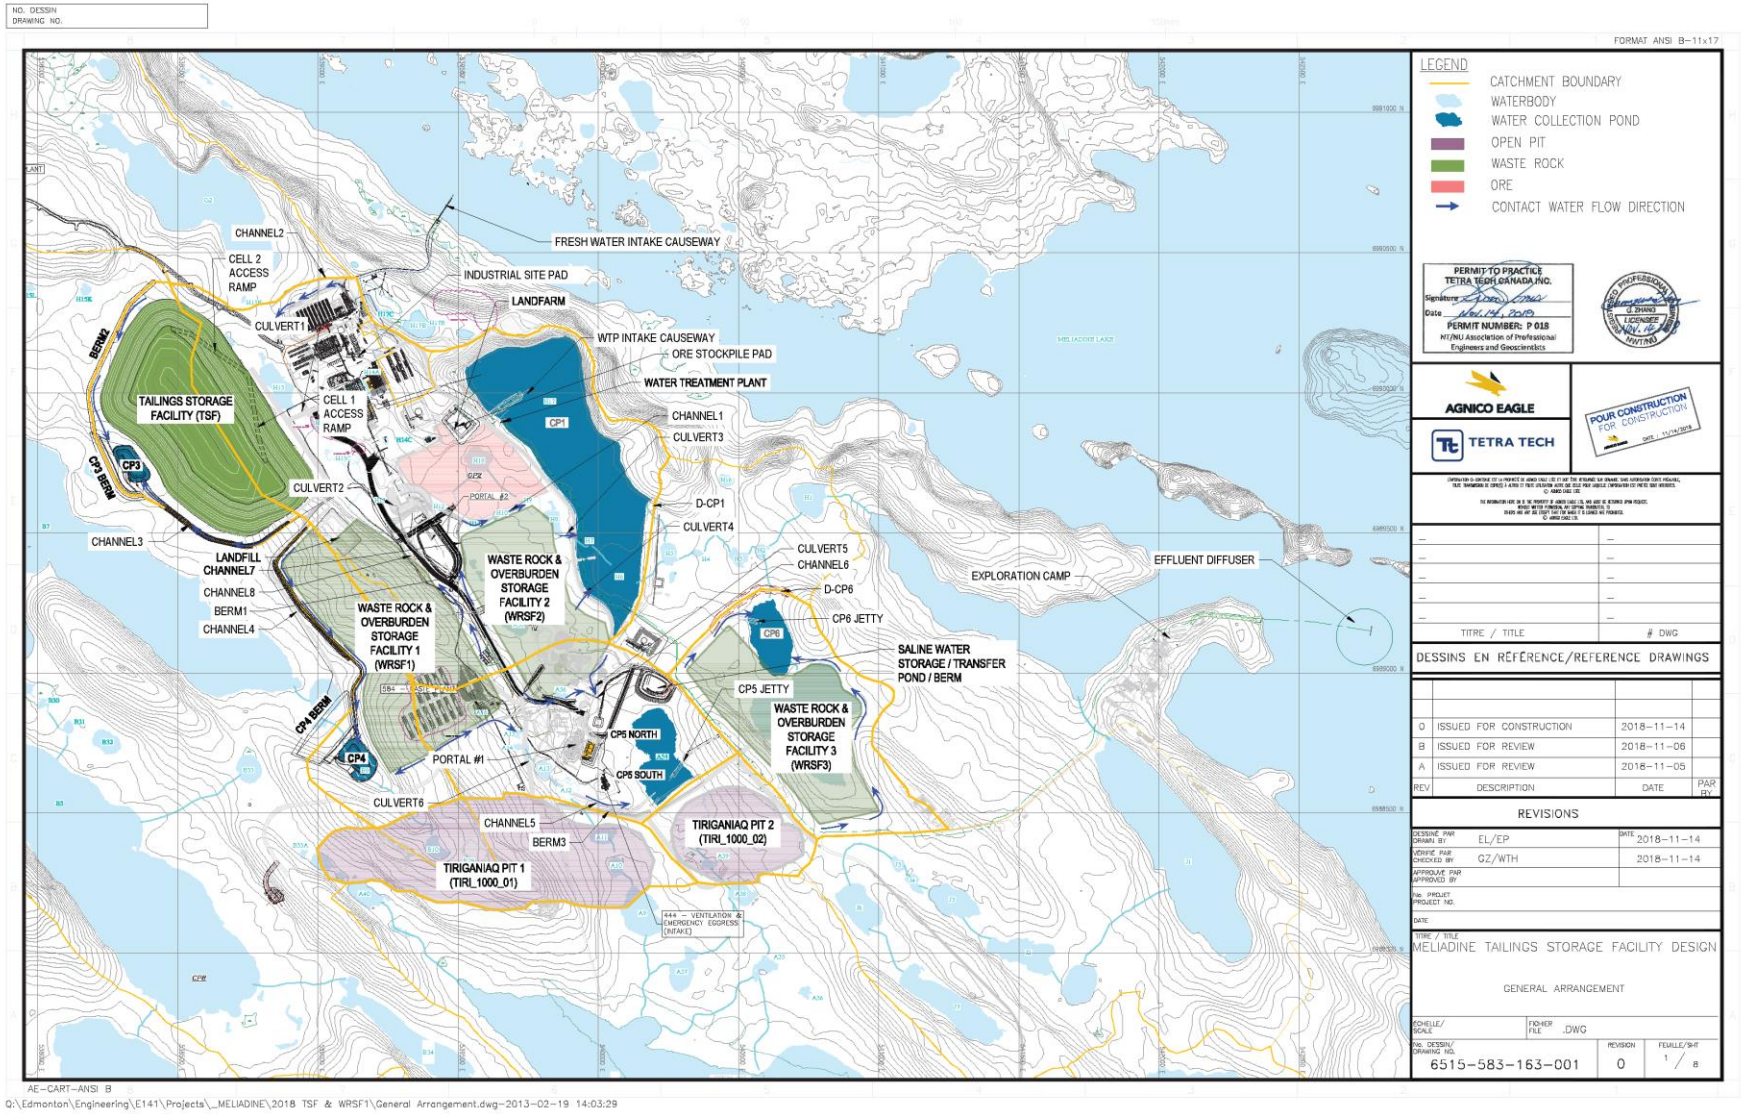

Figure 2.2 2018 Meliadine Site Sampling Locations

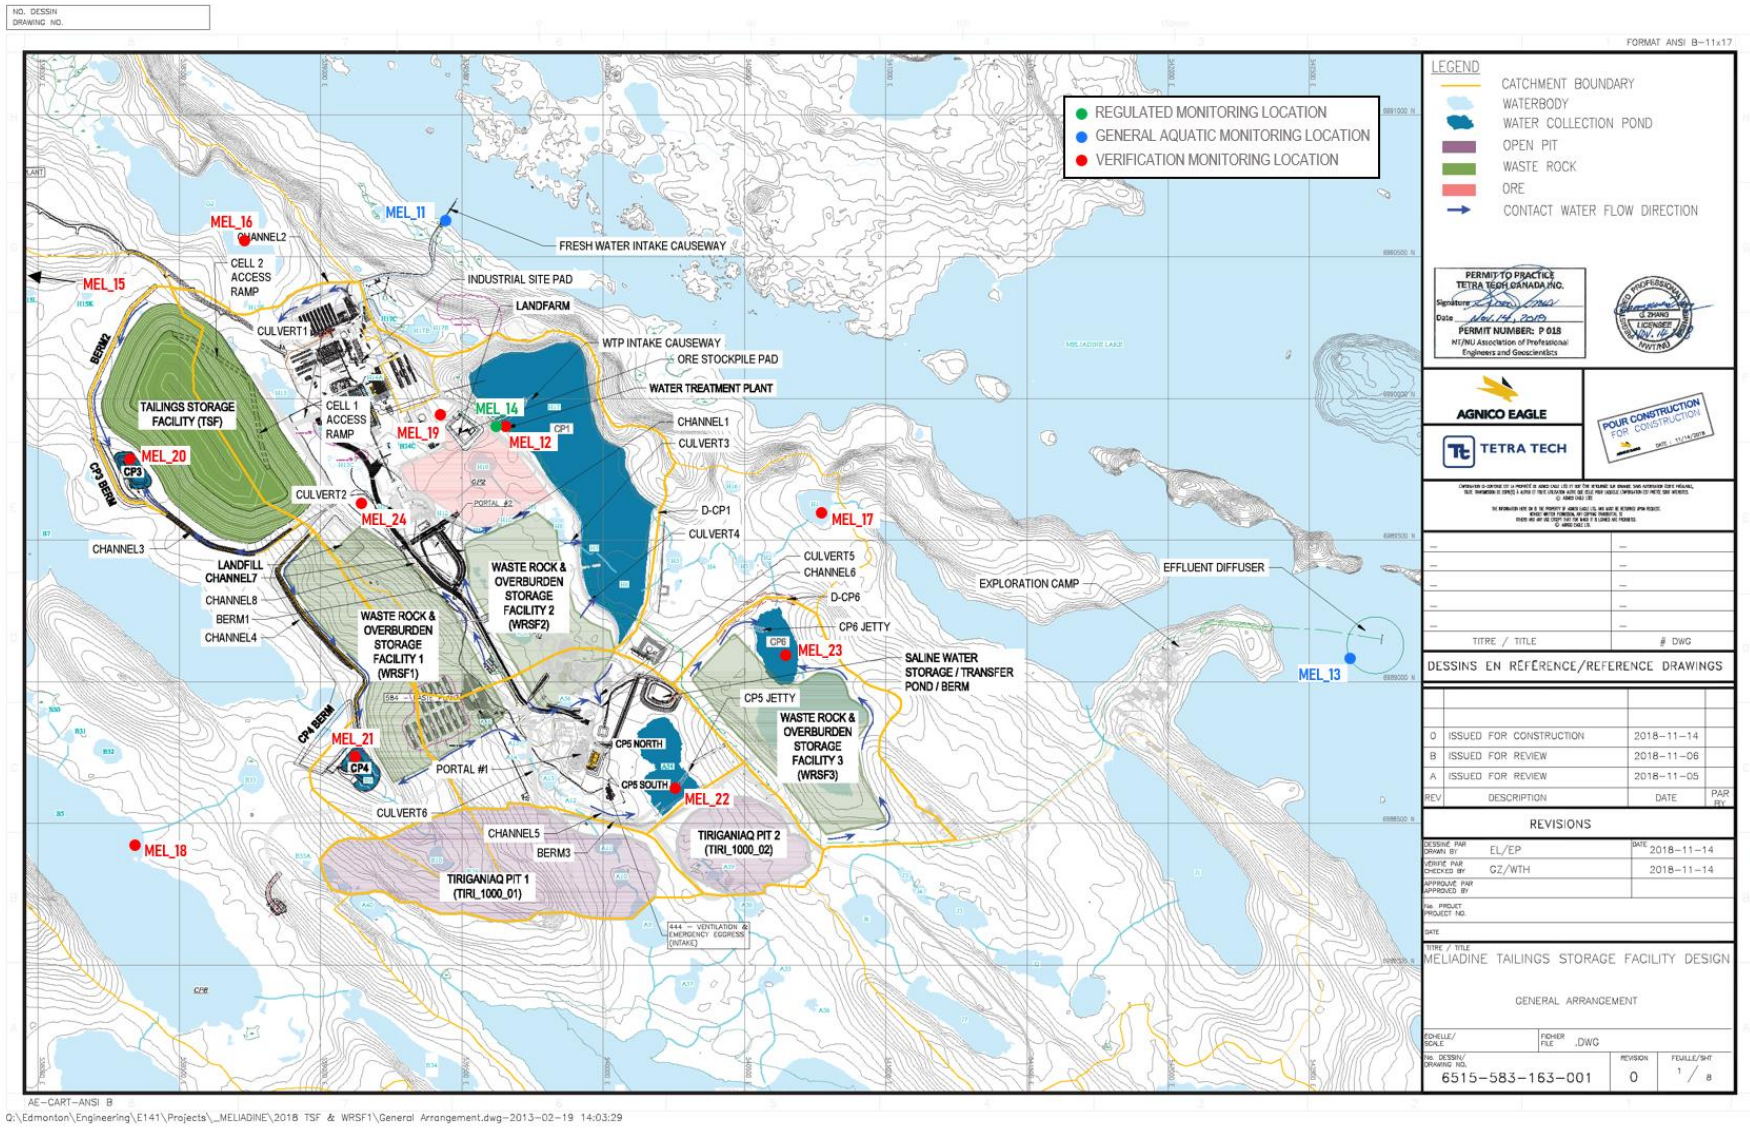

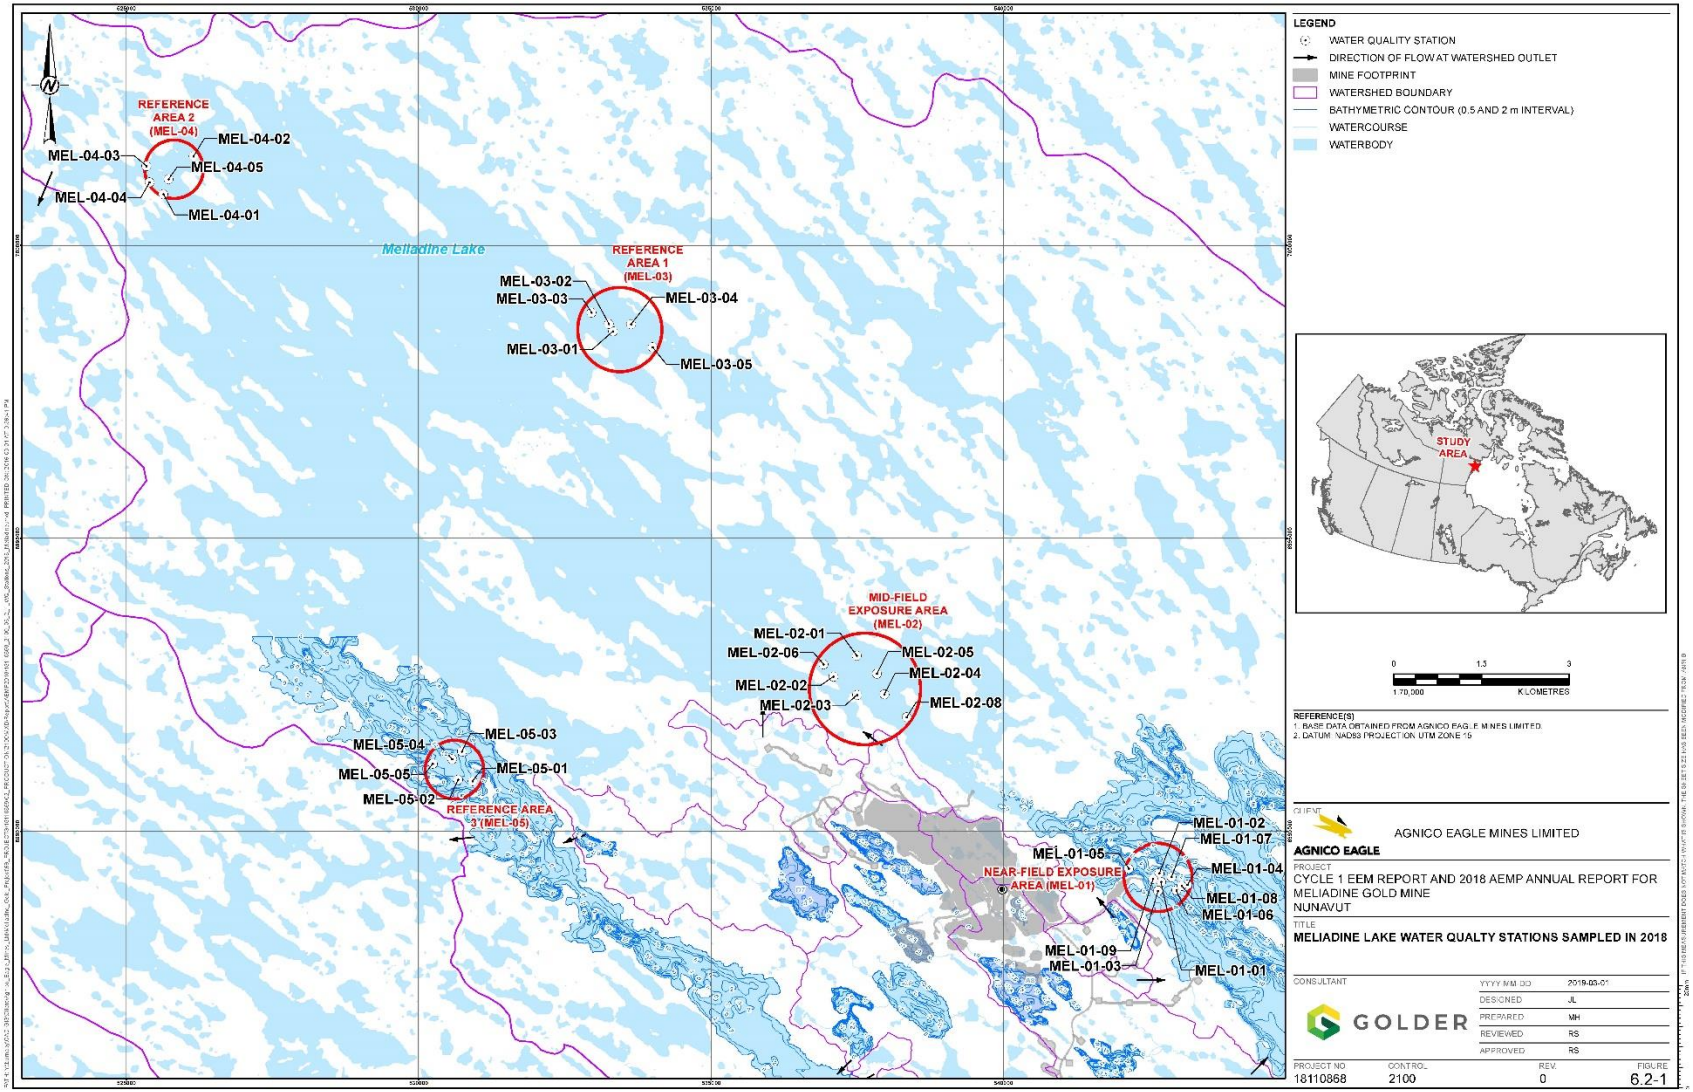

Figure 1.3 EEM Receiving Environment Sampling Locations

2.2 2019 MINE WORK PLAN

The 2019 Mine Plan for the Meliadine Gold Project, prepared for the Kivalliq Inuit Association as required by Production Lease KVPL11D01 was submitted to the KIA on January 22nd, 2019 and outlines the activities planned for the project throughout the 2019 year.

In 2019 the Meliadine gold mine will begin the operation phase of the project by mining the underground Tiriganiaq deposit. A total of 1 858 000 tonnes of rock will be extracted from the mine over the year. The mine plan consists of hauling 678 000 tonnes of waste rock, 135 000 tonnes of marginal ore and 1 045 000 tonnes of ore to the surface. Furthermore, approximately 380 000 tonnes of tailings will be returned underground, along with 60 000 tonnes of waste rock which will be used as rockfill. Waste rock and overburden will be trucked to the waste rock storage facilities (WRSFs) until the end of mine operation, with distribution according to an operation schedule. In 2019, 962 543 tonnes of solid tailings will be generated from the Mill. 380 517 tonnes of solid tailings will be used as underground backfill and 582 026 tonnes will be placed in the dry stacked Tailings Storage Facility (TSF).

Environmental monitoring (wildlife, aquatic effects, groundwater, noise and air) will continue through 2019 in support of all operational undertakings at the Meliadine site as required by the NWB Type A Water License 2AM-MEL1631, NWB Type B Water License 2BB-MEL1424, NIRB Amended Project Certificate No.006, and MDMER regulations.

In 2019, Agnico Eagle is planning to conduct the following construction projects that will be undertaken near the main mine site area and also on municipal and territorial leased land:

- Construction of Pond CP4 and associated infrastructure (Berm CP4, Channel 4);
- Finalize Portal 2 backfilling activities and associated water management structures;
- Complete construction of the Industrial Pad;
- Complete construction of Ore Storage Pad 2;
- Complete construction of Saline Pond 2;
- Finalize existing site roads;
- Finalize construction of the Paste Plant and;
- Construction and operation of the Saline Water Discharge tank at Itivia.

2.3 QUARRIES

In 2018, no material was taken from the quarries under permit KVCA11Q01. The total amount of material taken to date under this permit is 413,747 m^3 and the maximum allowed quantity to be taken is 650,000 m^3.

In 2018, 62,879 m^3 was taken from quarries under permit KVCA07Q08 for a total of 403,639 m^3. The maximum allowed quantity is 690,000 m^3.

As required under condition 16 for permit KVCA11Q01 and KVCA07Q08, monthly reports and payments were completed in 2018.

SECTION 3. WATER MANAGEMENT ACTIVITIES

3.1 WATER MOVEMENT

3.1.1 Fresh water obtained from Meliadine Lake

***As required by water license 2AM-MEA1631, Schedule B, Item 2: Monthly and annual volume of fresh Water obtained from Meliadine Lake*.**

Monthly and annual volume of fresh Water obtained from Meliadine Lake (MEL-11 and A-8) under License type A.

A total of 29,255 m³ of freshwater was withdrawn from Meliadine Lake in 2018, or approximately 47% of the maximum allowed (62,000 m³) under the License and indicated in Table 3.1.

Table 3.1: Volume of Fresh Water, withdrawn from Meliadine Lake and A8 in 2018

	January	February	March	April	May	June	July	August	September	October	November	December	**2018 Total**
Water withdrawn, m³	1,601	1,634	2,002	1,872	2,409	2,608	2,662	2,771	3,054	3,096	2,855	2,691	**29,255**

As required by Water License 2BB-MEL1424 Part B, Item 6a The Licensee shall obtain the daily, monthly and annual quantities in cubic meters of all freshwater obtained from Meliadine Lake at Monitoring Station MEL-1 and MEL-2;

Monthly and annual volumes of fresh Water obtained from Meliadine Lake (MEL-1 and MEL-2) under License type B.

Daily freshwater consumption details from Meliadine Lake (MEL-1 and MEL-2) under License type B can be found in Appendix A-1.

The monthly and annual water usage volumes are summarized in Table 3.2 below; a total of 20,651 m³ or 19% of the authorized amount (290 m³/ day ~ 106,000 m³/ year) was consumed in 2018.

Table 3.2 Monthly and annual quantities of freshwater in m^3, obtained from Meliadine lake at monitoring stations MEL-1 and MEL-2 in 2018.

	January	February	March	April	May	June	July	August	September	October	November	December	**2018 Total**
Water withdrawn, m^3	1,196	1,095	1,837	2,138	2,364	2,017	1,710	1,685	1,581	1,758	2,120	1,150	**20,651**

3.1.2 Fresh water obtained from Meliadine River.

As required by Water License 2AM-MEL1631 Schedule B, Item 4: Monthly and annual volume of fresh Water obtained from Meliadine River for road dust suppression activities.

In 2018, no water was obtained from the Meliadine River for road dust suppression activities; instead, water (240 m^3) was withdrawn from small ponds, proximal to the All-Weather Access Road (AWAR) as indicated in Table 3.3.

Table 3.3 Monthly and annual quantities of freshwater in m^3, obtained for road dust suppression activities.

	January	February	March	April	May	June	July	August	September	October	November	December	**2018 Total**
Water obtained, m^3	-	-	-	-	-	-	70	90	80	-	-	-	**240**

As required by Water License 2AM-MEL1631 Schedule B, Item 3: Monthly and annual volume of fresh Water transferred to Meliadine Lake as a result of dewatering activities.

No dewatering activities where water was transferred to Meliadine Lake took place in 2018.

3.1.3 Mine Water pumped from underground

As required by Water License 2BB-MEL1424 Part B, Item 6b The Licensee shall obtain the daily, monthly and annual quantities, in cubic meters, of Mine water pumped from the underground;

And

As required by Water License 2BB-MEL1424 Part B, Item 6j: Report all artesian flow occurrences

The daily, monthly, and annual flow volume quantities, in cubic meters (m^3), of mine water pumped from underground to surface during 2018 is summarized in Appendix A-2. There was no occurrences of artesian flow in 2018. The monthly and annual volumes of mine water pumped from the underground is summarized in Table 3.4 below with the water discharged from CP-1 to Meliadine Lake reported in Table 3.5.

Table 3.4 2018 Monthly and Annual flow volumes of underground mine water pumped to surface

	January	February	March	April	May	June	July	August	September	October	November	December	**2018 Total**
Water pumped, m^3	-	-	-	-	-	2,417	10,337	7,711	9,615	3,453	3,346	891	**37,766**

3.1.4 Water discharged from CP-1 to Meliadine Lake

Table 3.5 2018 Monthly and Annual volumes of water discharged from CP-1 to Meliadine lake

3.2 WATER BALANCE WATER QUALITY MODEL REPORTING SUMMARY

As required by Water License 2AM-MEL1631 Schedule B, Item 5: Summary of reporting results for the Water Balance and Water Quality model as required in Part E Items 11-12.

Water Quantity

The Meliadine water balance model was updated in January 2019 to provide a forecast of monthly inflows, outflows, and cumulative volumes for the 2019 calendar year in CP1, CP3, CP5, Saline Pond, Underground Mine, and P-Area (P1, P2, and P3). The update to the model occurred prior to Agnico Eagle receiving

ministry approval for saline effluent discharge to sea at the Meliadine site (reference). As such, the framework of the model does not account for saline water originating from the underground mine that will be removed from the site via discharge to Melvin Bay. The model is undergoing further revision to account for these and other changes to the water management strategies in place, and an update will be provided with the 2019 Annual Report.

None of the forecasted monthly cumulative volumes (end of months volume) in each containment facility exceed their respective operational maximum storage capacities. A summary of the reporting results of the water balance forecast are in Table 3.6. The numbers in brackets represent the maximum capacity for each pond.

Table 3.6 Summary of water balance model predictions generated in the January 2019 model update

	Maximum Capacity	January	February	March	April	May	June	July	August	September	October	November	December
CP1 m³	742,075	112,247	119,396	126,734	131,650	136,730	235,124	262,240	314,478	365,790	390,387	398,064	405,745
CP3 m³	28,000	-	-	-	-	-	25,454	25,454	25,454	25,454	25,454	25,454	25,454
CP5 m³	46,674	21,482	21,482	21,482	21,482	21,482	10,000	10,000	10,000	13,591	16,965	16,965	16,965
SP1 m³	32,686	13,743	13,743	13,743	13,743	13,743	24,628	22,920	23,451	22,715	22,851	22,851	22,851
Underground m³	129,213	6,760	4,184	1,931	1,931	1,931	2,098	3,283	9,184	14,374	16,000	17,170	17,170
P-Area m³	33,909	12,368	12,368	12,368	12,368	12,368	21,866	20,975	23,309	25,780	27,707	27,707	27,707

Water Quality

The water quality model was updated in January 2019 to provide a forecast of monthly average TDS concentrations for the 2019 calendar year in CP1, CP3, CP5, Saline Pond, Underground Mine, and P-Area (P1, P2, and P3). This update was generated by means of a mass balance applied to the water balance model update. As such, the water quality results are limited to the framework of the model and therefore do not account for saline water originating from the underground mine that will be removed from the site via discharge to Melvin Bay.

The presented TDS concentrations are the result of overly-conservative assumptions applied to the model update. As such, both the water balance and water quality model are undergoing revision in 2019 to address these deficiencies. Reporting results of the water quality forecast are presented in Table 3.7.

More information regarding the TDS concentration results presented can be found in Section 7.3 of the 2019 Water Management Plan

Table 3.7 Summary of water quality model predictions generated in the January 2019 model update.

	January	February	March	April	May	June	July	August	September	October	November	December
CP1 mg/L	1,970	1,879	1,797	1,746	1,710	1,805	2,330	2,786	3,027	3,175	3,223	3,171
CP3 mg/L	-	-	-	-	-	4,873	5,159	5,441	5,460	5,387	5,350	5,350
CP5 mg/L	12,200	12,200	12,200	12,200	12,200	5,593	4,334	5,706	5,630	6,914	7,950	7,950
Saline Pond 1 mg/L	14,809	13,903	13,903	13,903	13,903	20,261	19,989	19,071	18,078	17,786	17,737	17,737
Underground mg/L	55,798	55,791	56,058	55,800	55,800	55,800	55,800	55,800	55,800	55,800	55,800	55,800
P-Area mg/L	20,523	20,760	20,996	21,240	21,485	32,828	136,951	167,754	193,116	143,667	91,735	92,205

3.3 ADDITIONAL INFORMATION

As required by Water License 2AM-MEL1631 Schedule B, Item 23: ***Any other details on Water use or Waste Disposal requested by the Board by November 1st of the year being reported.***

And

As required by water license 2BB-MEL-1424 Part B Item 6n: Any other details on water use or waste disposal requested by the Board by November 1 of the year being reported

No additional information was requested in 2018.

SECTION 4. WASTE ROCK MANAGEMENT ACTIVITIES

4.1 GEOTECHNICAL MONITORING

As required by water license 2AM-MEL1631 Part I, Item 15: ***The Licensee shall submit to the Board as part of the Annual Report required by Part B, Item 2, a Geotechnical Engineer's Inspection Report. The Report shall include a cover letter from the Licensee outlining an implementation plan addressing each of the Geotechnical Engineer's recommendations.***

And

As required by water license 2AM-MEA1631, Schedule B, Item 1:

a. An overview of methods and frequency used to monitor deformations, seepage and geothermal responses;

The performance of the permanent dikes (D-CP1 and D-CP5) is assessed according to the guidelines provided in the Operation, Maintenance and Surveillance (OMS) manual for the facilities. This program consists of both documented visual inspections and geotechnical instrumentation monitoring. In 2018, visual inspections were conducted according to the following schedule:

- Bi-daily (every two days) - Conducted during freshet by a qualified engineer or technician;
- Weekly - Conducted during open water season by a qualified engineer or technician;
- Monthly – Conducted during open water season by the Agnico Eagle Geotechnical Engineer; and
- Annual – Conducted by a third party consulting engineer (Golder Associates Ltd.) during open water season.

All visual inspections are documented and include observations of cracking, settlement, seepage and deformation in addition to photographs. Any areas of movement are marked both physically on the dikes themselves by spray painting the locations and on plan drawings of the facilities in order to track changes in conditions.

In addition to the monthly documented visual inspection (during open water), a review of the operational performance and assessment of the geotechnical monitoring instrumentation is conducted every month by the Geotechnical Engineer. The schedule of collecting monitoring data in 2018 generally followed the OMS guidelines and is summarized in Table 4.1.

Table 4.1: Summary of 2018 Permanent Dike Geotechnical Monitoring Program

Instrumentation	Frequency of Data Collection
Thermistors	Bi-daily (freshet); Weekly (Open water); Monthly (Ice)
Survey Monuments	Monthly
Upstream Water/Ice Elevations	Daily (Open water); Monthly (Ice)

In addition to the permanent dikes, a geotechnical inspection and instrumentation monitoring program for the P-Area berms was also implemented by Agnico Eagle in 2018. Documented monthly inspections by the Agnico Eagle Geotechnical Engineer were conducted twice during open water season using the same

format and evaluation criteria as for the permanent dikes and the infrastructure in this area was also evaluated during the annual geotechnical inspection. Thermistor data was obtained and evaluated twice per week (freshet), weekly (remainder of open water) and monthly (winter). Water elevations were recorded daily throughout open water season.
The performance of all other water management and earthworks structures were assessed in 2018 during the Annual Geotechnical Inspection conducted by Golder Associates Ltd. The results of this inspection is available in Appendix B.

b. A comparison of measured versus predicted performance;

Based on the visual inspections and geotechnical monitoring data, the permanent water retention dikes (D-CP1 and D-CP5) are generally performing as expected, with no significant geotechnical concerns identified in 2018. Deformation, seepage and geothermal response will continue to be monitored as per the OMS guidelines throughout 2019. No significant geotechnical concerns were noted with any other water management or earthworks infrastructure during the annual inspection. The results of this inspection and detailed analysis is available in Appendix B.

c. A discussion of any unanticipated observations including changes in risk and mitigation measures implemented to reduce risk;

During dewatering activities in CP1 during the 2018 open water season, it was observed that the former H6 basin (immediately next to D-CP1) is at a higher elevation than the former H17 basin (at Jetty 1). Therefore, the maximum operating level for end of October (as per design and OMS requirements) could be achieved at the jetty but not near the dike. To connect the two systems and drain water away from the dike foundation towards the jetty, a small trench was mechanically excavated between the former H6 and former H17 basins on September 3 and 4, 2018.

d. As-built drawings of all mitigation works undertaken;

The as-built drawing of the trench between the former H6 and former H17 basins within the CP1 catchment area is located in Appendix B-3.

e. Any changes in the design and/or as-built condition and respective consequences of any changes to safety, water balance and water quality;

As-built condition was evaluated during the Annual Geotechnical Inspection (refer to Appendix B). Any deviations from design and the potential impact of those deviations are discussed during the construction record (as-built) reporting completed by the Design Engineer and submitted for review as per regulatory requirements.

In November 2017, Agnico Eagle determined that a reverse osmosis (RO) treatment system was required to manage TDS levels in water being transferred from CP5 to CP1. This requirement was due to an increasing trend of CP5 (MEL-22) TDS levels from 2016 (mean TDS = 2,579 mg/L; n = 19) to 2017 (mean TDS = 4,706 mg/L; n = 13). The RO system was procured in Q1 of 2018 and installed approximately 50 metres to the northeast of CP5 as a means to manage the increased TDS levels prior to moving water from CP5 to CP1, and eventually Meliadine Lake. Commissioning of the RO plant was completed on June

13, 2018, and the first transfer of treated CP5 water to CP1 took place on June 14, 2018. The RO system will continue to be used at CP5 for as long as TDS levels require treatment prior to transferring to CP1.

Although not a change to the design or as-built condition, the OMS for D-CP1 and D-CP5 was modified to reflect the actual as-built conditions of the Jetty 5 pumping station. The original version of the document had assumed that the invert of the lowest intake pipe had been installed to design elevation. During pumping activities from CP5 to CP1 however, it was observed that the elevation of the lowest intake pipe had been installed above the design elevation and that the maximum operating level before/after freshet was unachievable. Discussions with the Design Engineer (Tetra Tech) led to a revision of the OMS and increased maximum operating final elevation level for D-CP5 by 0.3 m.

f. Data collected from instrumentation used to monitor earthworks and an interpretation of that data;

4.1.1 Thermistors in the vicinity of the project

Thermistor cables have been installed to monitor natural ground temperatures in the vicinity of the Project. Data are presented in Appendix B along with plan views of thermistor installation locations. Several of these thermistors have stopped working over the last several years, mainly due to damage as construction of mine facilities expands into the areas where these thermistors have been installed. Readings taken in 2018 in the remaining operational thermistors are generally consistent with previous trends. There were some erroneous readings that have been removed from the plots for GT09-07, GT09-08, GT11-02, GT14-03, and GT14-27. These thermistors showed large jumps in temperature for one set of readings, which then returned to be in line with previous temperatures when they were read the next month. Most of the erroneous readings were on 6 September 2018. Thermistor GT14-03 also had erroneous readings on 19 June 2018 and GT14-27 had erroneous readings on 25 May 2018 and was then reported to be damaged.

Priorities and frequencies for reading these thermistors are summarized in AEM (2015c) and are based on the development sequence for the mine. Thermistors located in close proximity to the process plant and other mine infrastructure have the highest priority and are read more often. Thermistors located in the Tiriganiaq open pit area are given the next priority. The thermistors installed to monitor the deep permafrost are given the lowest priority as the conditions within the deep permafrost do not fluctuate seasonally, so fewer readings are required.

4.1.2 Thermistors in the P-area

DP1B thermistor (DP1B-1 and DP1B-2) data shows a maximum depth of temperatures above 0℃ of 2.8m (elevation 68.0 m) recorded on 30 September 2018. The nodes within the dike foundation remained below -1℃ during 2018.

DP2A thermistor (DP2A-1) data shows a maximum depth of temperatures above 0℃ of 3.6 m (66.04 m) recorded on 30 September 2018. The nodes within the dike foundation remained below -1℃ in 2018.

DP3A thermistor data (DP3A-1, DP3A-2, and DP3A-3) shows the maximum depth of temperatures above 0℃ varies between the three instruments. The data indicates that the greatest depth of 0℃ was measured at the central thermistor (DP3A-2 at station 0+150); this thermistor recorded temperatures

greater than 0℃ to its full depth (4.5 m) for four readings during the month of September 2018. Thermistors DP3A-1 (station 0+050) and DP3A-3 (station 0+250) identify a maximum depth of 0℃ measured at 4.4 m (elevation 64.67 m), and 2.7 m (elevation 66.37 m), respectively. The data from DP3-3 on 17 September 2018 is considered erroneous based on the readings collected before and after. The nodes within the dike foundation remained below 0℃ at DP3A-3, but temperatures rose above 0℃ to a depth of approximately 1.4m into the foundation below DP3A-1. Data from thermistor DP3A-2 shows that temperatures above 0℃ extend into the foundation from 19 July to 4 November 2018

In general, all thermistors showed all beads at or below 0℃ by 4 November 2018. The exception is thermistor DP1B-1 in which the last recording provided was for 30 September 2018; node 4 of this thermistor located within the dike fills remained at 1.0℃. This may be an erroneous reading as the nodes within the dike above and below node 4 showed consistent temperatures near 0℃.

4.1.3 Thermistors at D-CP1

The horizontal ground temperature cable plots (Appendix C2) were indicating a warming trend in the base of the key trench in 2017. They cooled over the winter with most of the nodes approaching temperatures near -10 °C in early June 2018. Temperatures measured from early June to late August 2018 showed a warming trend of about 2 to 3 °C, indicating influence of ambient temperatures and/or ponded water within CP1. Winter readings were not collected between January and June 2018 for three of the instruments, HGTC-1, HGTC-3, and HGTC-5. All horizontal ground temperature cable nodes at the base of the key trench have remained frozen based on the data provided. Some of the nodes that are located on the downstream slope of the key trench and along the foundation of the dike below the downstream slope had temperatures that rose above 0 °C, particularly HGTC-5 which has beads that extend below and possibly downstream of the rockfill shell. These nodes have less cover and are therefore more influenced by ambient temperatures Maximum temperatures may not have been reached as of the last readings provided for 1 September 2018.

Vertical ground temperature cable plots (Appendix C2) indicate that the dike and foundation remained below 0 °C after November 2017 throughout the winter until about April/June of 2018. The maximum depth of 0 °C temperature readings ranged from approximately 1.2 m to 2.7 m in the summer and early fall of 2018. The final readings received (1 September 2018) identified the greatest depth of 0 °C temperature readings at 2.7 m observed in VGTC-01, located upstream of the liner and key trench. The maximum depth of 0 °C temperature readings may not have been reached as of the last readings on 1 September 2018. The maximum depth of 0 °C temperature readings in 2017 was equal to the depths measured in 2018 or 0.5 m lower, with the exception of VGTC-05 which had a maximum depth of 0 °C 1.2 m lower than what was measured in 2018. All the vertical thermistors indicate that the foundation and the lower 1 to 2 m of the dike (both upstream and downstream of the liner) remained below 0 °C during the reporting period.

D-CP1 survey monitoring points M-1 to M-6 indicate a range of total vertical displacement between 29 and 40 mm between the baseline survey using the total station on 19 September 2017 to the last reading received for the reporting period on 13 August 2018. The range of total vertical displacement from the last reading in 2017 on 25 October to the last reading received for 2018 on 13 August was 18 to 25 mm. The maximum vertical displacement was observed at survey marker M-6 (station 1+510) and the minimum

vertical displacement was observed at survey marker M-2 (station 1+230). The OMS manual indicates that total vertical settlement less than 120 mm is an acceptable (green) condition.

4.1.4 Thermistors at D-CP5

The horizontal ground temperature cable plots initially indicated a warming trend after installation in the spring 2017. Beginning in January 2018, the data began showing a cooling trend. The cooling trend continued until about April 2018 and then started to warm as ambient temperatures increased. All thermistor nodes within the key trench remained at or below 0 °C throughout the reporting period (April 2017 to September 2018) and ranged from -3 to -10 °C. Maximum temperatures may not have been reached by the last readings on 1 September 2018.

Vertical ground temperature cables VGTC-01 and VGTC-02 are located upstream of the liner and key trench in D-CP5. The data from these instruments indicates that the upstream dike fills were below 0 °C from October 2017 until April 2018. The maximum depth of temperatures above 0 °C extended approximately 3.5 m to near the interface between the base of the dike fills and original ground at VGTC-01 and 3.0 m at VGTC-02. The depth of 0 °C temperatures appeared to be stabilizing in September but may not have reached the maximum depth. In 2017, the maximum depth of 0 °C temperature readings was 4 m at VGTC-01 and 3.5 m at VGTC-02. Up to the last reading on 1 September 2018, the foundation below the dike remained below -1 °C and -2 °C at the location of VGTC-01 and VGTC-02, respectively.

D-CP5 survey monitoring points M-1 and M-2 indicate total vertical displacement of approximately 20 mm between the baseline survey using the total station on 19 September 2017 to the last reading received for the reporting period on 21 July 2018. The range of total vertical displacement from the last reading in 2017 on 25 October to the last reading received for 2018 on 21 July was 9 to 12 mm. M-3 indicated a total vertical displacement of about 40 mm as of 25 October 2017. No additional readings were recorded for M-3 as it was reported as being destroyed. The OMS manual indicates that total settlement of less than 100 mm is an acceptable (green) condition

The 2018 Annual Geotechnical Inspection (Golder Associates Ltd., 2019) in Appendix B presents the complete instrumentation data

g. A summary of maintenance work undertaken as a result of settlement or deformation of dikes and dams; and berms

No maintenance work was undertaken in 2018 on any dikes, dams or berms.

h. The daily, monthly and annual flow volumes of any watercourse diverted during Construction activities

In September 2018, lake B8 and B9 were dewatered during three days for an average of 3,278 m³/day for a total of 9,834m³ which was transferred to CP-1 trough H13 and channel 1.

i. The daily, monthly and annual quantities of Seepage from dikes, dams and other structures in cubic metres.

Four seepages from dikes were visually observed along the dikes, downstream at DCP-1, DCP-5, DP-1 and DP-3 in 2018 and were captured by excavated trenches. The quantity of seepage is estimated from

flowmeter data; water, collected from trenches downstream from DCP-1 and DCP-5 dikes is metered and pumped back respectively to CP-1 and CP-5 while water, collected from trenches downstream from DP1 and DP3 dikes is metered and pumped back into P-Area ponds. The daily , monthly and annual quantities of seepage are provided in Appendix A-3

Table 4.2 Volumes of seepage, pumped from the trenches downstream from DCP1, DCP5, DP-1 and DP-3

	January	February	March	April	May	June	July	August	September	October	November	December	**2018 Total**
Pumped from DCP1, m³	0	0	0	0	0	10,704	533	0	0	0	0	0	**11,237**
Pumped from DCP5, m³	0	0	0	0	0	21,550	0	0	0	0	0	0	**21,550**
Pumped from DP-1, m³	0	0	0	0	0	432	806	8,050	0	0	0	0	**9,288**
Pumped from DP-3, m³	0	0	0	0	0	0	9,856	16,718	18,230	4,378	0	0	**49,182**
Total pumped m³	0	0	0	0	0	32,686	11,195	24,768	18,230	4,378	0	0	**91,257**

4.2 GEOCHEMICAL MONITORING

In accordance with Water License 2AM-MEL1631 Schedule B, Item 6: ***Geochemical monitoring results including:***

a. Operational acid/base accounting and paste pH test work used for waste rock designation (PAG and NPAG rock);

The acid/base accounting and paste pH test work used for waste rock designation is in the report located in Appendix C-1 and summarized below.

b. As-built volumes of waste rock used in construction and sent to the Waste Rock Storage Facilities with estimated balance of acid generation to acid neutralization capacity in a given sample as well as metal toxicity;

All of the waste rock was used for construction in 2018 as the Waste Rock Storage Facilities were not built yet.

c. All monitoring data with respect to geochemical analyses on site and related to roads, quarries, and the All Weather Access Road;

All data (mine site and quarries) can be found in the report located in Appendix C-1.

d. Leaching observations and tests on pit slope and dike exposure;

No leaching observations were found on dike exposure and no pit slope are present on site yet.

e. Any geochemical outcomes or observations that could imply or lead to environmental impact;

No environmental impact implied, as all test are NPAG, and within project predictions for no metal leaching impact.

f. Geochemical data associated with tailings solids, tailings supernatant, cyanide leach residue, and bleed from the cyanide destruction process including an interpretation of the data;

No tailings were produced in 2018.

g. Results related to the road quarries and the All Weather Private Access Road.

All results related to the road quarries and the All Weather Private Access Road can be found in the report located in Appendix C-1.

In 2018 Agnico Eagle conducted geochemical testing on waste rock material from underground development and surface material from approved quarries and eskers. Representative samples of this material were analyzed for Acid Rock Drainage (ARD) and metal leaching at the accredited third-party laboratory (SGS). Geochemical sampling program at Meliadine is comprised of two parts: mine development waste rock and quarry material.

4.2.1 Mine development waste rock

ARD Potential

Neutralization Potential

Neutralization potential (NP) is expected to be primarily provided by calcite and dolomite, with some ankerite (Golder 2014). As a result, carbonate analysis alone would likely be appropriate for determining NP, although both methods were used (i.e. titration and direct carbonate analysis). Complete results are provided in Appendix C-1. Golder (2014) indicated that NP from carbonate analysis (NP-Ca) was the more conservative method to determine buffering capacity of the rock and this was used as input into the ARD calculation. The relationship was checked in 2018, and the relationship generally held, especially at low NP values and therefore the continued used of NP-Ca was considered conservative for estimating ARD potential.

Acid Potential

Project prediction studies indicated that the main sulphide minerals in the waste rock was pyrite, but also included arsenopyrite, lesser pyrrhotite, and chalcopyrite (Golder 2014). As a result, the main consideration for acid potential (AP) is the presence of sulphide minerals at Meliadine.

Project prediction studies were confirmed in 2018 sampling with acid-base accounting testing showing that sulphur is primarily present in the sulphide form. Sulphur ranged from below detection 0.01% to a maximum of 1.6%, with a median of 0.18%.

ARD Assessment

The potential for ARD was assessed using NP-Ca/AP ratios (or neutralization potential ratios, (NPR). AP was calculated from total sulphur. Ratios below 2 were used to indicate potential for ARD (PAG or potentially ARD generating), whereas ratios above 2 indicate low potential for ARD (NPAG).

The classification of all Meliadine waste rock samples from underground since testing began in 2017 are provided in Appendix C-1. As predicted by Golder (2014), the majority of operational muck samples collected to date were NPAG. Samples from 2017 have also been included for ease of comparison to historical results. The one exception was a sedimentary sample with an NPR of 1.8. This sample is not considered a risk as there is excess buffering in all other samples collected and it is only marginally below the NPAG criterion. Given the carbonate mineralogy of the Meliadine samples, the threshold for a sample to produce ARD is likely closer to an NPR of one and this sample is unlikely to produce ARD even without the buffering of any other samples.

Metal Leaching

Metal leaching was predicted by Golder (2014) to be low enough that management of waste rock to inhibit leaching was not required. However, based on project screening studies, arsenic was determined to be the main element of interest and analysis of this element (and all regulated elements) were part of operational monitoring since mining began. A statistical summary for arsenic with complete element composition results is provided in Appendix C-1. To ensure arsenic concentrations were within project predictions, results have been compiled and compared against average and maximum arsenic concentrations reported by Golder (2014). Solid phase arsenic concentrations mainly fall within or below the average concentration, with no samples exceeding the maximum concentration reported by Golder (2014).

4.2.2 Quarry Material

ARD Potential

The potential for ARD from Quarry samples collected in 2018 was assessed by the same approach described above for waste rock, whereby NP was provided by carbonate (NP-Ca) and AP was estimated based on total sulphur. Complete results are provided in Appendix C-1. NP-Ca ranged from 2 to 44 kg $CaCO_3$/t, with a median of 9.2 kg $CaCO_3$/t. Total sulphur ranged from near detection limits of 0.01% to a 0.1%, with a median of 0.02%. These are relatively low sulphur numbers as typically any rock with less than 0.1% sulphur will not generate acidity regardless of the carbonate content as other rock components such as alkaline silicates (e.g. feldspars) can neutralize the small amount of acid produced. The potential for quarry material to produce ARD was based on NPR ratios, but also a sulphur limit of 0.1%, meaning that any samples with 0.1% or less sulphur would be NPAG regardless of the NPR ratio. Based on the two criteria, none of the quarry samples collected were PAG. The 0.1% sulphur criterion affected 4 out of 30 samples.

Metal Leaching

The same approach taken for waste rock was applied to quarry samples in terms of comparing against project prediction studies. All regulated elements were analysed in solid samples and are included in

Appendix C-1. Arsenic concentrations ranged from a minimum of 0.58 mg/kg to a maximum of 58 mg/kg, with a median of 5.3 mg/kg. These values are relatively low compared to waste rock and were within project prediction studies as the maximum value reported by Golder (2010) was 121 mg/kg. A statistical summary of all results since sampling began in 2017 are provided in Appendix C-1.

Based on geochemical characterization results obtained to date for the waste rock and quarry samples, there is low risk for ARD or metal leaching from the materials. Results are within project prediction studies for the project. Sampling will continue in 2019, with results reviewed internally as soon as they are available and provided with the 2019 annual report.

The complete Geochemical report is in Appendix C-1

Table 4.3. Summary of ARD Guidelines used to classify Meliadine Waste

Initial Screening Criteria	ARD Potential
NPR< 1	Likely Acid Generating (PAG)
1 < NPR < 2	Uncertain

4.3 WASTE ROCK VOLUME

In accordance with Water License 2BB-MEL-1424 Part B Item 6c An estimate of the current volume of waste rock and ore stockpiled on site;

Table 4.4. 2018 Excavated volumes (Tonnes)

	Ore	Marginal	Waste	Total
January	0	0	61,771	61,771
February	0	0	58,324	58,324
March	582	0	64,462	65,044
April	578	0	62,153	62,731
May	4,229	2,802	60,386	67,417
June	6,147	6,870	53,761	66,778
July	3,514	2,226	39,587	45,327
August	3,017	1,970	49,303	54,289
September	8,273	9,963	46,520	64,756
October	5,345	9,055	58,321	72,721
November	9,080	1,699	68,970	79,749
December	20,080	4,633	64,510	89,224
TOTAL	**60,846**	**39,216**	**688,069**	**788,132**

4.4 TAILINGS STORAGE FACILITY

4.4.1 Tailings Storage Facility Capacity*

As required by Water License 2AM-MEL1631 Schedule B, Item 7: ***An update on the remaining capacity of the Tailings Storage Facility.***

In 2018, no tailings was sent to the tailings storage facility so the remaining capacity according to further construction is still 10.9Mt as stated in the Mine Waste Management Plan.

4.4.2 Tailings Freezeback and Capping Thickness

As required by Water License 2AM-MEL1631 Schedule B, Item 16: ***A summary of on-going field trials to determine effective capping thickness for the Tailings Storage Facility and Waste Rock Storage Facilities for the purpose of long term environmental protection.***

In 2018 no on-going field trials to determine effective capping thickness for the Tailings Storage Facility and Waste Rock Storage Facilities occurred as production has not started yet.

* TSF- Tailings Storage Facility

SECTION 5. WASTE MANAGEMENT ACTIVITIES

5.1 LANDFILL MONITORING, WASTE ROCK STORAGE FACILITY

As required by Water License 2AM-MEL1631 Schedule B, Item 8*: Summary of quantities and analysis of Seepage and runoff monitoring from the Landfill, Landfarm, Waste Rock Storage Facilities, Borrow pits and Quarries.*

Landfill and Landfarm were commissioned in November 2017. No seepage was observed from either facilities in 2018. Monitoring and inspection will continue on a regular frequency.

The Waste Rock Storage Facility infrastructures approved under water license 2AM-MEL1631 has not been built yet.

No seepage was observed around operating quarries and borrow pits located on site and along the AWAR as per regular inspections completed by the Environment Department.

5.2 GENERAL WASTE DISPOSAL ACTIVITY

As required by Water License 2AM-MEL1631 Schedule B, Item 9: A summary report of all general waste disposal activities including monthly and annual quantities in cubic metres of waste generated and locations of disposal.

All waste, produced at Meliadine, falls into 4 major categories:

1) Hazardous waste;
2) General (dry, non-hazardous) waste;
3) Food waste; and
4) Contaminated soil.

Hazardous waste, such as waste coolant, used oil filters, waste grease, used batteries, sewage sludge etc. is segregated according to material type, stored in sea containers, and shipped south during the sealift season. All hazardous waste on site was shipped by Nunavut Sealink and Supply Inc., to Qikiqtaaluq Environmental Services facility in Quebec, via Port of Bécancour.

In 2018 a total of 3,274 tonnes of hazardous waste was shipped south in 50 sea containers; documentation for the transfer of hazardous waste can be found in Appendix D-1.

General waste, such as glass, concrete, wood and ash was landfilled on-site and off-site. Type A landfill was commissioned in November 2017 with the volume of landfilled waste being estimated through periodic surveys. An estimated 5,868 m³ of waste was placed into Type A landfill during 2018. Monthly volumes are indicated in table 5.1. In September 2018, the landfill was expended to contain an extra 11,000 m³

(landfill stage 2). In 2018, some activities occurred in Landfarm A to remediate the soils. The material was screened, windrowed and nutrient amendment was done. Sampling and follow up will be done in 2019. The recycling wood option with the community is something Agnico Eagle will investigate in the future to lower the amount of material sent to the landfill.

Food waste, including food packaging, was incinerated to avoid landfilling the material, and attracting the wildlife. Produced ash was landfilled. Monthly quantities can be found in table 5.1

Contaminated soil was placed into landfarm A for treatment. Type A landfram was commissioned in November 2017 with an estimated 2,853 m³ of contaminated soil being placed there in 2018 mainly from the clean up of the fuel farm and exploration genset spills that occurred in 2017.

In 2018 a total of 1,676.4 tonnes of material was shipped south for recycling, including scrap metal, waste oil, batteries and electronic waste.

The incinerator approved under Water License 2AM-MEL1631 was commissioned at the end of November 2017; the incinerator test were undertaken in 2018.

Table 5.1. 2018 Volume of waste transferred to the incinerator, landfill and the landfarm

Month	Volume of waste send to incinerator (m³)	Volume of waste send to landfill (m³)	Volume of contaminated soil placed in Landfarm A (m³)
January	378	578	4
February	352.8	578	0
March	352.8	577	0
April	365.4	548	15
May	352.8	548	1,620
June	315	549	300
July	340.2	548	3
August	327.6	548	0
September	315	549	882
October	340.2	282	27.5
November	352.8	281	1
December	340.2	282	1
Total	**4,132.8**	**5,868**	**2,853.5**

5.3 INCINERATOR

As per Water License 2AM-MEL1631 Schedule B, Item 10: ***Report of Incinerator test results including the materials burned and the efficiency of the Incinerator as they relate to water and the deposit of waste into water.***

Agnico Eagle hired Consulair to sample the atmospheric emissions at the outflow of the incinerator. As can be observed in Table 5.2, the applicable standards for dioxins and furans (PCDD/F) were met for all tests, as well as the applicable standard for mercury (Hg). The standards originate from the "Environmental Guideline for the Burning and Incineration of Solid Waste" emitted by the Department of Environment of the Government of Nunavut based on the Canadian Council of Ministers of the Environment (CCME) Canada - Wide Standards for Dioxins and Furans and Mercury Emissions. The complete report can be found in Appendix E-1.

Agnico Eagle also proceeded with incinerator Ash testing. Unfortunately, analyses were requested for acid extractable instead of metals leachate Agnico Eagle followed up with the laboratory to see if re-analysis were available but unfortunately, the samples were disposed by the lab. A sample was taken early February 2019 and the analysis request was modified to ensure proper analyses is performed from now on. The results from this sample were significantly lower than the guideline for industrial waste discharge and are provided in the table 5.3. A sample will be taken every quarter to ensure compliance with the guideline in 2019.

Table 5.2. 2018 Stack Testing Mercury and Dioxine and Furane Results

Applicable Standards		
Contaminants	Test Results	Standards
Mercury (Hg)	0.23 µg / Rm³ @ 11 % v/v O_2	20 µg / Rm³ @ 11 % v/v O_2
Dioxins ans Furans (PCDD/F)	0.042 ng / Rm³ @ 11 % v/v O_2	0.08 ng TEQ / Rm³ @ 11 % v/v O_2

Table 5.3. 2018 Incinerator Ash Monitoring

Parameters	**Units**	2018/02/23	2018/03/17	2018/04/14	2018/05/13	2018/09/15	2018/10/15	**Guideline for Industrial Waste Discharge (mg/L)***	2019/02/10 (results are in mg/L)

Footnotes: * Government of Nunavut Environmental Guideline for Industrial Waste Discharges (D of SD, 2011).

5.4 ADDITIONAL INFORMATION

As required by Water License 2AM-MEL1631 Schedule B, Item 23: ***Any other details on Water use or Waste Disposal requested by the Board by November 1st of the year being reported.***

And

As required by water license 2BB-MEL-1424 Part B Item 6n: Any other details on water use or waste disposal requested by the Board by November 1 of the year being reported

The Board did not request any additional details on waste disposal in 2018.

SECTION 6. SPILL MANAGEMENT

As per Water License 2AM-MEL1631 Schedule B, Item 11 ***A list and description of all unauthorized discharges including volumes, spill report line identification number and summaries of follow-up action taken.***

And

As required by water license 2BB-MEL-1424 Part B Item 6f: A list of unauthorized discharges and a summary of follow-up actions taken

In 2018, a total of 22 reportable spills including 7 license exceedances (grey shade) occurred at Meliadine compared to 14 in 2017. All spills were reported to the 24-hour spill reporting line as required by the Government of Nunavut's, Environmental Protection Act, paragraph 5.1(a), the conditions under the Nunavut Water Board License 2AM-MEL1631 Water Licence, part H, item 8(b) or the conditions under the Nunavut Water Board License 2BB-MEL1424, Part H, item 4. For all reportable spills, a follow up report was submitted 30 days or less following the event as required under the Nunavut Water Board License 2AM-MEL1631 Water Licence, part H, item 8(c).

All reportable spills/exceedances are summarize in table 6.1. Complete reports and follow up reports can be found in Appendix F-3.

Table 6.1. 2018 Reportable spills or limit exceedances

Date of spill/exceedance	Hazardous Material	Quantity for spills or analyses results for exceedance	Location	Cause of the spill
January 31st, 2018	Sewage	~500L	Lift station	Equipment failure
February 2nd, 2018	Sewage	~120,000L	Retention tank	Human error
February 18th, 2018	Diesel fuel	2,578L	Genset Fuel tank	Human error
May 27th, 2018	TSS	500 mg/L	Itivia area	Freshet
June 3rd, 2018	TSS	420 mg/L	Itivia area	Freshet
June 8th, 2018	Hydraulic oil	N/A	Near Lake B8	Equipment failure
June 10th, 2018	TSS	160 mg/L	Itivia area	Freshet
June 12th, 2018	Sewage	~3,000L	Lift station	Ground thaw
June 17th, 2018	TSS	670 mg/L	Itivia area	Freshet
June 20th, 2018	TSS	260 mg/L	Itivia area	Freshet
July 8th, 2018	Sewage sludge	~200L	Sewage Treatment Plant	Equipment failure
July 11th, 2018	Hydraulic oil	~5L	Itivia area	Equipment failure
July 20th, 2018	Treated sewage	~3000L	Road between explo camp and main camp	Human error
July 23rd, 2018	Treated effluent	4.39 mg/L (Aluminum)	CP-1 discharge (MEL-14)	Assumed to be a laboratory error
August 2nd, 2018	Treated sewage	1600L	Retention tank	Human error
August 19th, 2018	Treated effluent	1430 mg/L (TDS)	CP-1 discharge (MEL-14)	Equipment failure/Human error
August 25th, 2018	Sewage	~200L	Retention tank	Equipment failure

September 20th, 2018	Treated sewage sludge	100L	Old landfarm area	Human error
October 4th, 2018	Diesel fuel	844L	Refueling station	Human error
October 30th, 2018	Sewage	~1000L	Retention tank	Equipment failure
November 17th, 2018	Treated sewage water	100L	Retention tank	Weather
December 11th, 2018	Boiler system water	200L	Main camp area	Equipment failure

A risk assessment for spills has been initiated; AEM has identified and rectified deficiencies related to fuel spills. In areas of higher risk for spills, such as the fuel dispensing system at Itivia, a lined secondary containment was put in place to lower the risk of spills causing an offsite impact. Another example of AEM lowering the risk of exceedances is that all treated effluent from the Exploration camp STP is trucked to CP1 – a containment system. The risk assessment process is ongoing as new systems are commissioned.

AEM has noted that although the number of spills has increased in 2018, the severity has decreased which confirms procedures have improved. In addition, an improved training program has led to an increased understanding of spill reporting and an overall level of improved general awareness with regards to spills and spill reporting. Based on this, it is believed that more spills are being reported on site by employees.

To prevent and ensure all spills are reported internally, spill prevention training was provided to employees in 2018. Training activities include the following:

- All employees and contractors must participate in an induction session online prior to the arrival at the mine site, which includes a training section on spill management (prevention, reporting and cleaning).

- Every employee and contractor who operates a vehicle on site must participate in training on vehicle operation. Spill management is a component of this training session.

- Department toolbox meetings were completed in 2018 regarding environmental situations including spills prevention. The presentation and the attendance sheets can be found in Appendix F-1.

- A mock spill exercise was completed on August 4th, 2018 at the Itivia tank farm. The mock scenario involved a broken fuel line fitting at the onshore receiving manifold during refueling (from offshore ship) at the fuel storage tanks at Itivia. Agnico Eagle's Environmental staff lead the exercise, which included AEM emergency response (ERT) members, Orbit Garant Environmental/health representative, safety, AEM warehouse staff, AEM Site Service/KHTO vice president and AEM community relations personnel. AEM environmental technician documented the spill actions as well as acted as the "Control Room" responder. The exercise was used to gain experience on spill intervention and awareness of spill management gear. Overall, the reaction of participants was satisfactory and lessons learned from the event will ensure a more efficient future response, if needed. Mock scenario complete report can be found in Appendix F-2.

Table 6.2. 2018 Non-reportable spills

Date of spill	Hazardous Material	Quantity (l)	Location	Cause of the spill	Describe immediate corrective actions
January 13, 2018	Engine Oil	10	Industrial Pad	Hose or seal broken	Contaminated snow picked up and disposed of adequately.
January 21, 2018	Anti-Freeze	2	Explo Parking Lot	Mechanical leak	Contaminated snow was removed.
January 22, 2018	Sewage	50	Portal	Shut off valve was left open	Spill was contained and contaminated soil picked up and disposed of appropriately.
February 3, 2018	Hydraulic Oil	8	Esker	Mechanical leak	Spill was contained and contaminated snow picked up and disposed of appropriately.
February 12, 2018	Hydraulic Oil	4	Fuel Farm Tank 32	Mechanical leak	Used absorbent to clean the oil, shoveled the contaminated snow and brought into the landfarm.
February 12, 2018	Hydraulic Oil	4	Fuel Farm Tank 30	Mechanical leak	Used absorbent to clean the oil, shoveled the contaminated snow and brought into the landfarm.
February 21, 2018	Engine Oil	3	Exploration Camp	Mechanical leak	Spill was contained and contaminated snow picked up and disposed of appropriately.
February 21, 2018	Hydraulic Oil	2	Industrial Pad	Mechanical leak	Contaminated snow picked up and disposed of adequately.
March 3, 2018	Steering Fluid	6	Site Roads	Broken Hose	Contaminated snow picked up and disposed of appropriately.
March 4, 2018	Steering Fluid	1	Industrial Pad	Leaking hose	Contaminated snow picked up and disposed of appropriately.
March 6, 2018	Engine Oil	3	AWAR	Engine fail	Contaminated snow picked up and disposed of appropriately.
March 8, 2018	Diesel Exhaust Fluid	3	Warehouse yard	Mechanical leak	spill pads were put in place and the snow picked up and disposed of appropriately.
March 11, 2018	Oil	1	Audit & Knight yard	Frozen hose	They did some modification on the unit so that the issue was resolved.
March 13, 2018	Grey Water	40	Camp	Hose left unsecured	Spill was contained and contaminated soil picked up and disposed of appropriately.

March 14, 2018	Hydraulic Oil	7	Industrial Pad	Hydraulic hose failure	Spill was contained and contaminated soil picked up and disposed of appropriately.
March 26, 2018	Torqueless (non-contaminant)	10	Drill SH:84	Product transfer	Material has been cleaned with a vacuum.
March 30, 2018	Coffee	0	Camp	Coffee poured outside	Contaminated snow picked up and disposed of adequately.
March 31, 2018	Steering Fluid	0	Explo Camp parking lot	Leaking hose	scooped up snow fluid and put in pail and disposed of appropriately.
April 7, 2018	contaminated water with glycol	4	New camp	Radiator blew up	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
April 8, 2018	Waste oil	10	FRONT DOME 2	Leaking hose	They put the spill pad under the equipment ,they fix the problem and move the equipment , they clean all the waste oil and put it in the hazmat.
April 13, 2018	Hydraulic oil	19	Construction Pad	The valve manifold cap seal has blown	Replace the seal and contaminated material picked up and disposed of appropriately.
April 21, 2018	Engine Oil	1	Other	Pump leak	Contaminated snow picked up and disposed of adequately.
April 22, 2018	Hydraulic Oil	10	Industrial Pad	Broken O'ring	Spill was contained and contaminated soil picked up and disposed of appropriately.
April 25, 2018	Hydraulic Oil	2	Maintenance Shop	Mechanical leak	Spill was contained and contaminated soil picked up and disposed of appropriately.
April 26, 2018	Hydraulic Oil	8	Industrial Pad	Broken Hose	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
May 5, 2018	Differential oil gear case	3	Batch plant	Gear case oil leak	Remove contaminated snow and ice put it in 2 x 5 gallons pale and disposed of appropriately.
May 5, 2018	Hydraulic oil leak	1	Dion Parking lot	Leaking hose	We shoveled material into a bucket and brought the contaminated material to the landfarm.
May 6, 2018	Hydraulic Oil	10	South Side of A&K Dome	Mechanical leak	Chipped contaminated ice and put into land farm.
May 12, 2018	Diesel	10	DCP1 Road Side	Fuel Tank leak	Contaminated material picked up and disposed of appropriately.

May 20, 2018	Other - unknown oil type	30	Maintenance Shop	Equipment failure	Contaminated soil picked up and disposed of in the landfarm.
May 22, 2018	Diesel	5	Itivia Area	Mechanical leak	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
May 22, 2018	Hydraulic Oil	1	Orbit Yard - Explo Camp	Broken oil tank	They cleaned the oily sport with matting.
May 27, 2018	Fuel	5	SH:84 Surface Drill 2	Leaking hose	Contaminated material picked up and disposed of appropriately.
May 28, 2018	Waste Oil	60	In front of MSB building	Leaking Tote	Contaminated material picked up and disposed of appropriately.
June 1, 2018	Oil	2	By pass road culvert installation	Leaking hose	1 cu ft of contaminated material was recovered and properly disposed of.
June 6, 2018	Coolant	1	North side of construction office	Mechanical leak	Contaminated soil picked up and disposed of in the landfarm.
June 9, 2018	Diesel Fuel	3	Other	Mechanical leak	Install booms in water puddles- soak up material with rags.
June 14, 2018	Diesel	95	Industrial Pad	Overfilling	Contaminated soil picked up and disposed of in the landfarm.
June 14, 2018	Diesel	25	Industrial Pad	Overfilling	Contaminated soil picked up and disposed of in the landfarm.
June 15, 2018	Diesel	3	Process Plant	Leaking tank	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
June 18, 2018	Diesel Fuel	5	Itivia	Broken seal	Contaminated soil picked up and disposed of in the landfarm.
June 18, 2018	Hydraulic Oil	10	Industrial Pad	Mechanical leak	Contaminated soil picked up and disposed of in the landfarm.
June 30, 2018	Oil	3	Site road	Broken oil pan	Install matting tow equipment to the garage, spill been cleaned.
July 4, 2018	Hydraulic Oil	20	Industrial Pad	Leaking hose	Contained the spill and disposed of absorbent pads.
July 4, 2018	Hydraulic Oil	8	Ouest side portal 2	Hose failure.	Installed a new hose and contaminated material picked up and disposed of appropriately.
July 4, 2018	Hydraulic Oil	10	Hydraulic Oil	Hose failure.	Installed new hose and contaminated material picked up and disposed of appropriately.

July 9, 2018	Gasoline	2	Electrical laydown	Leaking tank	used spill pads to soak up fuel and then removed berm and disposed of soil used for berm to landfarm (~4 m3).
July 11, 2018	Hydraulic Oil	5	Other	Leaking hose	Spill was contained and contaminated soil picked up and disposed of appropriately.
July 17, 2018	Hydraulic	10	375 RP3	leaking hose	Contaminated soil picked up and disposed of in the landfarm.
July 26, 2018	Diesel	1	Industrial Pad	Leaking tank	Spill was contained and contaminated soil picked up and disposed of appropriately.
July 31, 2018	Diesel	20	Itivia Area	leaking tank	Grave was scooped with a loader and was brought to the landfarm.
August 4, 2018	Diesel	5	Industrial Pad	Fuel nozzle issue	Spill was contained and contaminated soil picked up and disposed of appropriately.
August 13, 2018	Hydraulic fluid	58	Entrance 375 West	Broken Hose	Spill was contained and contaminated soil picked up and disposed of appropriately.
August 17, 2018	Hydraulic fluid	40	FW2-425-E	Broken Hose	Spill was contained and contaminated soil picked up and disposed of appropriately.
August 20, 2018	Hydraulic Oil	2	Other	Broken O'ring	Spill was contained and contaminated soil picked up and disposed of appropriately.
August 24, 2018	Transmission oil	15	In front of MSB door	Filter casing failed	pick up oil with dedicated absorbent pads brought to HAZMAT.
August 28, 2018	Diesel	2	Site Roads	Left over in piping	Spill was contained and contaminated soil picked up and disposed of appropriately.
September 21, 2018	Transmission Oil	2	WASTE PAD Portal 1	Leaking hose	used spill kit to clean and contain the spill with another operator.
September 24, 2018	Engine Oil	1	Industrial Pad	Mechanical leak	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
October 4, 2018	Hydraulic Oil	5	Transfer Pad	Mechanical leak	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
October 4, 2018	Diesel	50	Other	Tank overflow	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
October 6, 2018	Engine Oil	60	Industrial Pad	Oil Filter came loose	Spill was contained and contaminated soil picked up and disposed of in the landfarm.

October 7, 2018	Coolant	4	Site Roads	Broken radiator	Spill was contained and contaminated soil picked up and disposed of appropriately.
October 24, 2018	Hydraulic Oil	30	Industrial Pad	Broken Hose	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
October 24, 2018	Antifreeze	10	In front of MSB	Mechanical leak	Spill was contained and contaminated soil picked up and disposed of appropriately.
October 25, 2018	Other	1	Ore Storage	Leaking hose	Spill was contained and contaminated soil picked up and disposed of appropriately.
October 29, 2018	Diesel	40	Paste Plant Bore Hole	Fuel transfer	Spill was contained and contaminated soil picked up and disposed of appropriately.
November 2, 2018	Windshield washer fluid	1	Site Roads	tank overflow	Contaminated snow picked up and disposed of adequately.
November 9, 2018	Antifreeze	3	parking area warehouse office Itivia Site	Mechanical leak	Warehouse clerk removed contaminated snow into drum.
November 16, 2018	Diesel	50	Gas boy	Fuel cap improperly screwed	Spill was contained and contaminated soil picked up and disposed of appropriately.
November 17, 2018	Diesel	25	Tiriganiaq Esker	Frozen trigger valve on nozzle	Spill was contained and contaminated soil picked up and disposed of in the landfarm.
November 19, 2018	Coolant	11	In front of MSB door #5	Coolant leaked from the radiator	Picked up the coolant with dedicated absorbent pads.
December 6, 2018	0w/40	12	M182506	Cracked Hydraulic Cooler	Absorbent pads were put down and contaminated snow picked up and disposed of appropriately.
December 7, 2018	0W/40	10	M182506	Hydraulic hose connection failed	Hose was changed. Material picked up and disposed of properly.
December 15, 2018	Diesel	40	Vent Raise	Frozen trigger valve on nozzle	Contaminated snow picked up and disposed of adequately.
December 28, 2018	Waste Oil	5	Explo Laydown	Leaking tote	Spill was contained and contaminated soil picked up and disposed of in the landfarm,
December 31, 2018	Hydraulic oil	20	Batch Plant	Loose hydraulic hose	Spill was contained and contaminated soil picked up and disposed of in the landfarm.

SECTION 7. MONITORING

As required by Water License 2AM-MEL1631 Schedule B, Item 14:
The results of monitoring related to the Environmental Management and Protection including:

a. Aquatic Effects Monitoring Program;

Refer to section 7.1, all results can be found in Appendix G-1.

b. Metal and Diamond Mining Effluent Regulation (MDMER) Monitoring;

Refer to section 7.2, all results can be found in Appendices H-1 and H-2.

c. Mine site Water quality monitoring, including groundwater monitoring; and

Refer to section 7.3, all results can be found in Appendix H-3.

d. Visual AWAR Water quality monitoring

Refer to section 7.4.

and

As required by Water License 2BB-MEL-1424 Part B Item 6d: ***Tabular summary of all data generated under the Monitoring Program,***

Sampling is no longer required from the water Licence 2BB-MEL-1424, explanation is provided in section 7.3.1.

7.1 AQUATIC ECOSYSTEM MONITORING PROGRAM (AEMP)

Volume 7 of the FEIS for the Meliadine Gold Project (Mine) predicted inputs of nutrients, metals, and major ions to Meliadine and Peninsula Lakes. It was predicted that these inputs would result in minor changes to water and sediment quality in Meliadine Lake, and that any corresponding effects on fish and fish habitat would be negligible (Agnico Eagle 2014). The component sections of the annual AEMP report are designed to characterize changes in measures related to contaminant and nutrient input, and related responses in phytoplankton, benthos, and fish. The purpose of the integrated summary is to synthesize the results for each component to evaluate the overall direction of change to the aquatic ecosystem. The objective of the synthesis is to:

- integrate AEMP findings from all components
- determine the strength of support for each impact hypothesis and effects on the ecosystem
- support decision making for management responses

The integrated summary is part of the overall objective of the AEMP to assess potential mine-related effects on the aquatic ecosystem and to meet regulatory requirements outlined in the Type A Water

License (2AM-MEL1631) and MDMER, while also meeting commitments made during the environmental permitting process. The specific objectives of the AEMP are to:

- determine the short- and long-term effects of the Project on the aquatic receiving environment
- evaluate the accuracy of predictions made in the FEIS, including the final significance statements regarding impact to the aquatic ecosystem
- assess the efficacy of planned mitigation incorporated into the Project design
- collect data required to identify the need for potential additional mitigation of Project effects within a management response framework

The 2018 AEMP program consisted of water quality, sediment quality, benthic invertebrate community, and a phytoplankton targeted study in Meliadine Lake, and water quality monitoring in selected peninsula lakes. The 2018 fish health survey was implemented to meet EEM sampling requirements and was not intended to meet the specific requirements of the Mine's AEMP fish health component (Section 10.1). However, the 2018 fish health results are discussed as part of this integrated summary to evaluate potential mine-related effects on biological components. The next AEMP fish health and fish tissue chemistry program is scheduled for 2021.

The results of the 2018 AEMP study in Meliadine Lake and the peninsula lakes (water quality and phytoplankton only) were evaluated in the context of the key questions proposed for each core component in the AEMP Design Plan (Golder 2016). The key questions and a summary of the results for each component are presented in Table 12.2-3 and discussed below. The results of the effluent chemistry and toxicity testing program are also discussed in the context of the results of the AEMP components, where relevant.

7.1.1 Peninsula Lakes Summary and Conclusions

Changes in some water quality parameters over time were observed in Lakes A8, B7, and D7. However, all parameter concentrations were less than their respective water quality guidelines, were within normal ranges, and aligned with FEIS predictions. The water quality dataset for the peninsula lakes for the pre-construction and construction phase was limited, and potential factors accounting for temporal trends were not identified in this report. A phytoplankton targeted study was also conducted in the peninsula Lakes in 2018, with collection of chlorophyll α data. No findings of significance were identified as part of the 2018 phytoplankton study of the peninsula lakes.

7.1.2 Meliadine Lake Summary

Potential mine-related changes in water quality in Meliadine Lake were observed in the Near-field area in 2018 for specific conductivity, TDS, hardness, several major ions, and a number of total metals; concentrations exceeded the upper bound of their respective normal range and increased in the Near-field and relative to reference areas over time. Water Licence exceedances in the effluent were observed for TDS and total aluminum. However, the exceedance of total aluminum WL limit occurred only in one sample, with other effluent samples noticeably lower in concentration, suggesting that the measured

value may be anomalous. In addition, although total aluminum concentrations were higher in the Near-field area, there was no indication of declining concentrations with distance from the diffuser. Concentrations of a few metals in bottom sediments exceeded the upper bound of their respective normal range, but exceedances were marginal and sediment metal concentrations in the Near-field area did not increase relative to the reference areas over time. Concentrations of water quality parameters were less than it's guidelines.

The 2018 AEMP results indicated that the benthic community was not measurably affected by potential Mine-related changes in water or sediment quality in Meliadine Lake. Lower density and BCI values were observed in the Near-field area (relative to pooled reference areas), but values were within the normal range. Therefore, differences among these areas may be attributed to pre-discharge differences in sediment composition and natural spatial variation. Effects on fish health were not observed in 2018, with the exception of an effect on female condition in the Near-field area relative to Reference Area 1. The magnitude of effect on female condition did not exceed the 10% critical effect size and a similar difference was not observed in supporting energy storage endpoints. No other effects on fish health were reported in 2018. The comprehensive AEMP fish health program was not conducted in 2018 as it is scheduled in 20121 and as such an evaluation of fish tissue was not conducted.

Low Action Levels for toxicological impairment or nutrient enrichment were not triggered by the 2018 AEMP results.

7.1.3 Meliadine Lake Conclusions

The results of the water quality monitoring program suggest a Mine-related effect on water quality in the Near-field and Mid-field areas. Baseline (pre-2015) and pre-construction and construction phase (2015 to 2017) water quality data were evaluated as part of the normal range screening (Appendix 6B). The assessment indicated a change in major ion concentrations in the Near-field area, and a potential change in the Mid-field area compared to the 2015 to 2017 data, relative to pre-2015 data collected periodically between 1995 and 2013 in Meliadine Lake. This evaluation, in combination with the qualitative temporal analysis conducted as part of the 2018 AEMP water quality program (Section 6.4.5), suggest a potential pre-construction effect on water quality, as well as a potential effect on water quality for selected parameters during treated mine effluent discharge in 2018. However, the changes in water quality in Meliadine Lake were within the conditions predicted by FEIS. Mine-related effects on sediment quality were not observed in 2018.

Observed changes in key water quality parameters in 2018 did not translate into effects in the biological components in 2018, with respect to major ions and total metals. However, the nutrient enrichment effect observed in prior AEMP monitoring years continued to be observed in some biological components in 2018. A phytoplankton targeted study was conducted as part of the 2018 AEMP monitoring program; this program is not a formal component under the AEMP Design Plan (Golder 2016) but was planned as a targeted study prior to 2019 to evaluate the usefulness of plankton monitoring for future monitoring. Higher chlorophyll α concentrations and phytoplankton biomass, and unique phytoplankton community structure were observed in the Near-field area (relative to Mid-field and reference areas), indicating potential nutrient enrichment originating from the exploration camp STP discharge. Chlorophyll α and phytoplankton biomass were within the ranges observed during the pre-construction phase of the Mine,

suggesting that nutrient enrichment may have begun prior to the discharge of treated mine effluent from MEL-14.
Mine-related effects on the benthic invertebrate community were not observed in 2018. However in 2016, mean density fell outside of the upper bound of the normal range in the Near-field area, potentially due to the influence of exploration camp STP discharge. Total phosphorus loadings approximately doubled in sewage effluent in 2016 (corresponding to an increase in Mine population), and held steady in 2017, prior to declining in 2018 (Section 2.6.2). Total Phosphorus (TP) loadings did not correspond to observed spatial or temporal TP water quality trends in the Near-field area but median TP concentrations were slightly elevated in 2016 and 2017, relative to 2015 and 2018. An effect on female condition factor observed during the fish health program also aligns with potential nutrient enrichment in the Near-field area.

Overall, nutrient enrichment in Meliadine Lake may have begun in 2016 with expansion of the Mine population and increased STP nutrient loading into the lake. Effects observed in phytoplankton, benthos and fish biological components are consistent with mild nutrient enrichment. Although effects in benthos were not observed in 2018, effects on phytoplankton were evident in the Near-field area despite a reduction in sewage TP loadings; TP loadings in 2018 were lower relative to 2016/2017 loadings and relative to baseline (i.e., 2013 and 2015). Additionally in 2018, a stimulatory effect on freshwater algae growth (*Pseudokirchneriella subcapitata*) was observed during sublethal toxicity testing with effluent; this further supports the potential for nutrient enrichment in Meliadine Lake as a result of Mine effluent discharge. Lastly, increased major ion and some total metal concentrations in lake water in the Near-field area were observed, and are indicative of a Mine-related effect.

Similar to nutrient enrichment, major ion concentrations and increases in selected total metal concentrations were observed in the Near-field area during pre-construction and continued to increase during the construction phase. It is likely that the exploration camp STP discharge contributed to increases in these parameters. However, concentrations are within the range of FEIS predictions and have not translated into increased concentrations in the sediment, or effects on biological components. Future AEMP monitoring programs will continue to monitor for spatial and temporal trends.
The complete AEMP/EEM cycle 1 report can be found in Appendix G-1.

7.2 MDMER AND EEM SAMPLING

This section relates to the monitoring programs conducted under the Metal and Diamond Mining Effluent Regulations (MDMER) and its Environmental Effects Monitoring (EEM) Studies. Reporting requirements for MDMER have been submitted directly to Environment and Climate Change Canada; results are presented herein to comply with the NWB Type A Water License A list of the sampling location GPS coordinates can be found in table 7.1. Certificates of Analysis for EEM are included in Appendix H1.

Table 7.1 MDMER and EEM GPS coordinates

Station ID	GPS coordinates
MEL-14 (Effluent characterization)	63˚2'15.5"N 92˚13'06.3"W
MEL-13 (Water Quality Monitoring Exposure Area)	63˚01'44.6"N 92˚09'14.6"W
MEL-03-01 (Water Quality Monitoring Reference Area)	63˚06'52.2"N 92˚20'23.6"W

Discharge of treated effluent from CP-1 to Meliadine Lake started June 21st and ended September 3rd 2018. A total of 642,521 m^3 of water was discharged. As requested in Schedule 6 of the Metal and Diamond Mining Effluent Regulations, monthly mean concentrations, pH range and volume of effluent (generated) can be found in Appendix H-2. Monitoring results for MDMER discharge are in the table 7.2 below. No exceedance occurred in 2018 for the MDMER and EEM sampling

7.3 MINE SITE WATER QUALITY

As required by Water License 2AM-MEL Schedule B-13: The results and interpretation of the Monitoring Program in accordance with Part D and Part I and Schedule I.

7.3.1 ***Licensed Water Sampling Stations***

Below is the monitoring stations from water Licence 2AM-MEL1631 and 2BB-MEL-1424. All sampling results can be found in Appendix G-3. For each station a summary is provided and for stations with sufficient data, an interpretation of the data is given. Also, for all stations regulated by MDMER or Licence limits, a graph with critical parameters was added. All monitoring stations results can be found in Appendix H-3.

7.3.1.1 ***MEL-1 Raw water supply intake at Meliadine Lake***

MEL-1 is the raw water supply intake at Meliadine Lake for the exploration camp. No sampling is required only volume as provided in section 4.

7.3.1.2 ***MEL-2 Raw water supply intake at Pump, A8 or other Lakes***

MEL-2 is the raw water supply intake at A8 or other lakes. No sampling is required only volume as provided in section 4.

7.3.1.3 ***MEL-5 Bermed Fuel Containment Facilities***

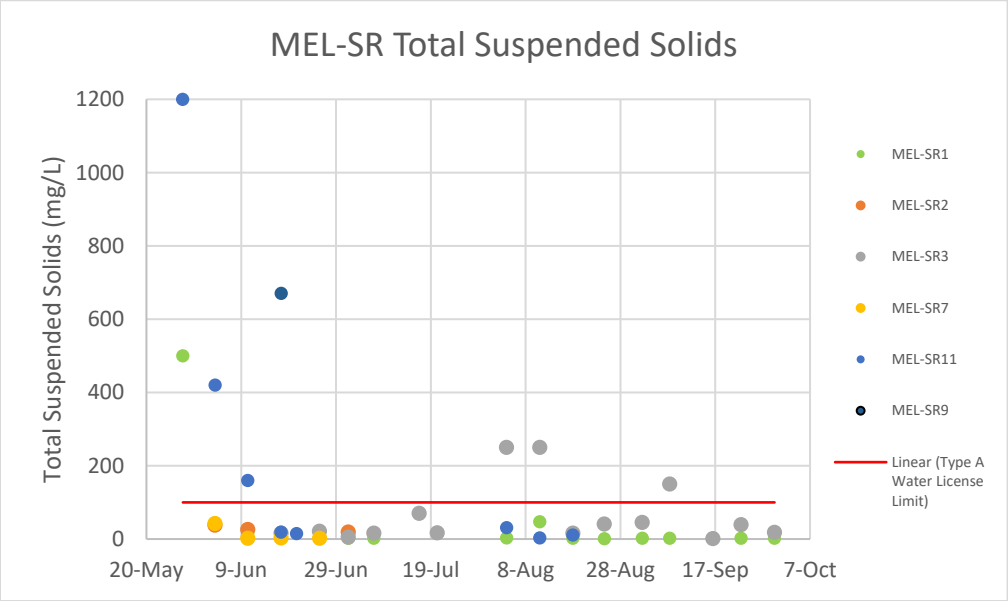
MEL-5 was the point of discharge for the bermed fuel containment facilities for the exploration camp. It was decommissioned so no sampling is required anymore.

7.3.1.4 ***MEL-6 Landfarm Treatment Facility***

MEL-6 is the effluent from the Landfarm Treatment Facility prior to release. The landfarm is not decommissioned yet but no water was released since 2016 as the water is transferred to the landfarm oil separator system and treated before being discharged in CP-1.

7.3.1.5 ***MEL-7 Effluent from Exploration camp STP***

MEL-7 is the final effluent discharge from the biodisk at the exploration camp. Since November 2017, the treated water from the exploration STP is trucked to CP-1. Monitoring for this station still occurs to ensure the efficiency of the treatment system but no discharge occurs anymore directly to Meliadine Lake.



7.3.1.6 ***MEL-8 Point of discharge or runoff from the Non-Hazardous Waste Landfill***

MEL-8 was the point of discharge from the non-hazardous waste landfill for the exploration camp. It was decommissioned so no sampling is required anymore.

7.3.1.7 ***MEL-SR-1-TBD***

MEL-SR-TBD are surface runoff – runoff downstream of construction areas at Meliadine Site and Itivia Site, seeps in contact with roads, earthworks and any runoff and/or discharge from borrow pits and quarries. These are regulated monitoring stations in the water licence which includes discharge limits that must be achieved to maintain compliance.

Figure 7.1 TSS results for MEL-SR samples

In 2018, a few TSS exceedances occurred at the Itivia laydown area during freshet. A sediment trap has been built to minimize additional TSS flow and this area will be further investigated in 2019. Silt fences and straw logs have also been installed upstream and downstream of the site and were inspected weekly. A third party consultant has inspected the area to recommend improvements to mitigate and reduce erosion and sediment control. The snow management plan has been revised and some work is planned to improve the TSS management in 2019.

However, it's important to note that sampling also occurred upstream of Agnico Eagle Lease showing the upstream contribution of TSS prior to arriving on Agnico Eagle site exceeded licence requirements. It is believed that the majority of the TSS that was observed downstream of Agnico Eagle Lease was a result of sediment generated upstream of the lease boundary. Monitoring of the area will be done during freshet and a reassessment will be done to see if other stakeholders need to be included in this project. Samples were also taken from the shore in the bay (MEL-SR-03) as a background sample to allow for comparison in between the surface runoff and the bay itself.

7.3.1.8 ***MEL-11 Water Intake***

MEL-11 is the water intake from Meliadine Lake. It is an aquatic monitoring location which is subject to compliance assessment to confirm that sampling is carried out using established protocols, including quality assurance/quality control provisions, and addresses identified issues. General monitoring is subject to change as directed by an Inspector, or by the Licensee, subject to approval by the NWB.

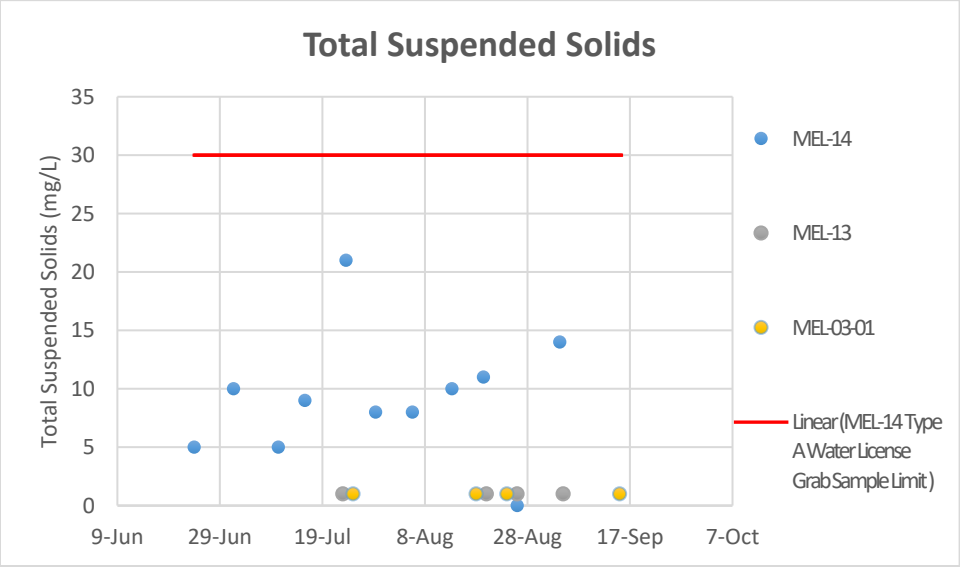
7.3.1.9 ***MEL-12 Water treatment plant (Pre-treatment)***

MEL-12 is sampled in the effluent water treatment plant (EWTP) (pre-treatment) sampling port with the water coming from CP1. The sample is not taken directly in the pond. It is a verification monitoring program location which is to be carried out for operational and management purposes by the Licensee.

Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.1 ***MEL-03-01 Reference area in Meliadine Lake (MDMER reference station)***

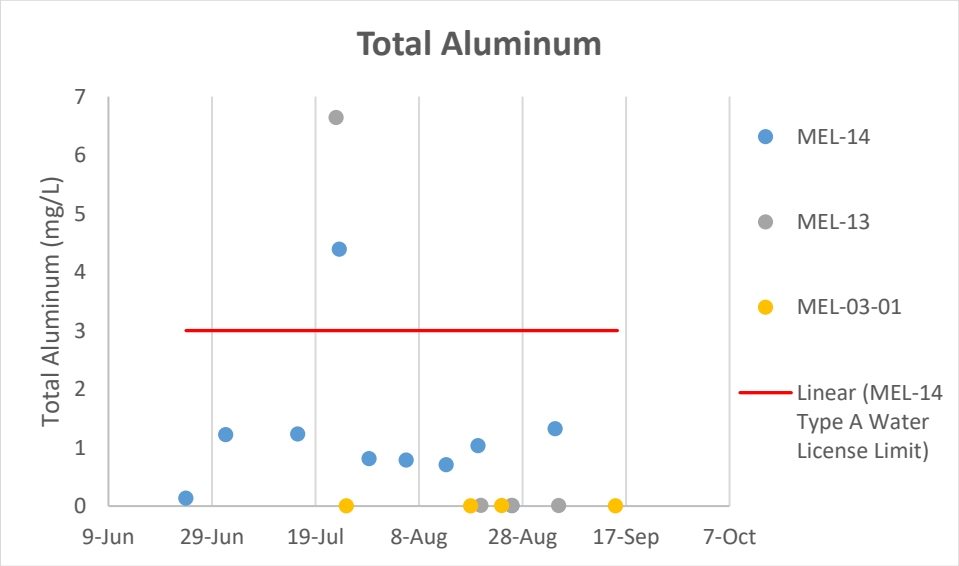
MEL-03-01 is sampled in Meliadine Lake. It is also the MDMER reference station for final discharge. It is a general aquatic monitoring location which is subject to compliance assessment to confirm sampling is carried out using established protocols, including quality assurance/quality control provisions, and addresses identified issues. General monitoring is subject to change as directed by an Inspector, or by the Licensee, subject to approval by the NWB. Figure 7.2 to 7.4 below show the analytical trends of interest for MEL-03-01 for 2018



7.3.1.2 ***MEL-13 Mixing Zone in Meliadine Lake (MDMER exposure station)***

MEL-13 is sampled in the mixing zone in Meliadine Lake. It is also the MDMER exposure station for final discharge. It is a general aquatic monitoring location which is subject to compliance assessment to confirm sampling is carried out using established protocols, including quality assurance/quality control provisions, and addresses identified issues. General monitoring is subject to change as directed by an Inspector, or by the Licensee, subject to approval by the NWB. Figure 7.2 to 7.4 below show the analytical trends of interest for MEL-13 for 2018

7.3.1.3 ***MEL-14 Water treatment plant (Post-treatment)***



MEL-14 water originates from CP-1 and is sampled in the effluent water treatment plant (EWTP) (post-treatment) prior to the water being discharged to the environment. It is a regulated monitoring station in the water licence and in the MDMER regulation. It includes discharge limits that must be achieved to maintain compliance. Figure 7.2 to 7.4 below show the analytical trends of interest for MEL-14 for 2018.

Figure 7.2 TSS results for MEL-03-01, MEL-13 and MEL-14 samples

In 2018, the TSS results for MEL-14 were stable with no significant increase or decrease of concentration. The yearly average concentration was 9.27 mg/L and the highest result was 21 mg/L. No exceedance occurred in 2018 for this parameter with all daily and monthly results within permitted limits. For MEL-13, all TSS results were 1 mg/L and for MEL-03-01, all results were below the detection limit of 1 mg/L.

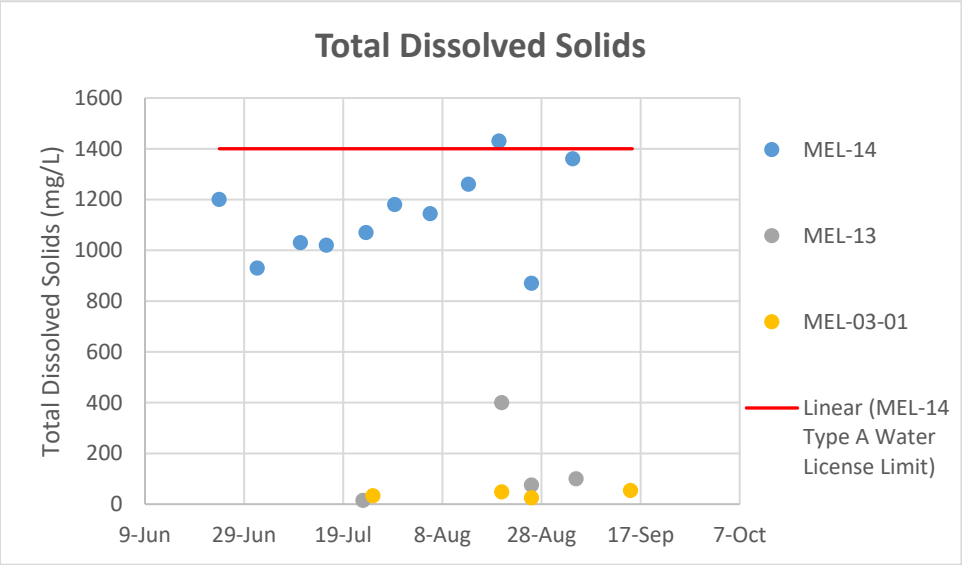


Figure 7.3 Aluminum results for MEL-03-01, MEL-13 and MEL-14 samples

In 2018, the aluminum results for MEL-14 were stable with no significant increase or decrease of concentration except for one sample. On July 23rd, a sample from the final discharge point (MEL-14) was collected and sent for analysis. The results were received and the total Aluminum concentration exceeded those outlined in the 2AM-MEL-1631 Type A Water Licence Part F Item 3. The result was 4.39 mg/L, which exceeds the Licence limit of 3 mg/L. The result for dissolved aluminum for the same sample is 0.0994 mg/L. The exceedance for final effluent discharge for total aluminum concentration is assumed to be a laboratory error. When the exceeded criteria was observed, the lab was requested to re-analyze the sample to determine if the reported concentration was a result of laboratory error; however, the sample had been disposed of and re-analysis was not possible at the date of the request. A uncharacteristically high result (6.64 mg/L) for the same parameter was obtain the same day for a sample taken in Meliadine Lake (MEL-13) which is more than 600 times the average of the other sampling results for the same location.

The average concentration for aluminum at MEL-14 in 2018 was 1.1 mg/L and the highest result was 4.39 mg/L. The average concentration for aluminum at MEL-13 in 2018 was 1.67 mg/L (due to the uncharacteristically high result of 6.64 mg/L. The average concentration for aluminum at MEL-03-01 in 2018 was 0.004 mg/L and the highest result was 0.007 mg/L

Figure 7.4 TDS results for MEL-03-01, MEL-13 and MEL-14 samples

In 2018, the TDS results for MEL-14 increased progressively during summer as expected. The dry and windy conditions amplified the evaporation process which increased the TDS concentration. The stratification between saline and freshwater likely also affected the TDS concentration as pumping occurred. On August 19th a sample from the final discharge point (MEL-14) was collected and sent for analysis. The results were received and the total dissolve solid (TDS) concentration exceeded those outlined in the 2AM-MEL-1631 Type A Water Licence Part F Item 3. The result was 1430 mg/L, which exceeds the Licence limit of 1400 mg/L. A duplicate was taken that day and the result was 1400 mg/L.

The average concentration for TDS at MEL-14 in 2018 was 1135 mg/L and the highest result was 1430 mg/L. For MEL-13 the average concentration in 2018 was 148 mg/L and the highest result was 400 mg/L. The average concentration at MEL-03-01 in 2018 was 40 mg/L and the highest result was 54 mg/L.

All exceedances mentioned above were reported to the 24-hour spill reporting line as required by the Government of Nunavut's, Environmental Protection Act, paragraph 5.1(a), the conditions under the Nunavut Water Board License 2AM-MEL1631 Water Licence, part H, item 8(b).

The Environment Department at Meliadine implemented in 2018 a data management system for laboratory results. The system should mitigate delays with reporting criteria exceedances and improve the timing for requests that may be made if re-analysis is required at the laboratory.

7.3.1.4 ***MEL-15 Local Lake E3***

MEL-15 is sampled in lake E3 located west of the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.5 ***MEL-16 Local Lake G2***

MEL-16 is sampled in lake G2 located north west from the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.6 ***MEL-17 Local Pond H1***

MEL-17 is sampled in lake H1 located east from the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.7 ***MEL-18 Local Lake B5***

MEL-18 is sampled in lake B5 located south-west from the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.8 ***MEL-19 CP-2***

MEL-19 is sampled in CP-2 (collection pond) which is the collection of the natural catchment drainage from the outer berm slopes of the Landfarm and industrial pad. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee. No water accumulate in this area in 2018, therefor no sample was taken.

7.3.1.9 ***MEL-20 CP-3***

MEL-20 is sampled in lake B28 and will be sampled in CP-3 (collection pond) once construction is completed. CP-3 will be the collection of drainage from dry stacked tailings located west of the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.10 ***MEL-21 CP-4***

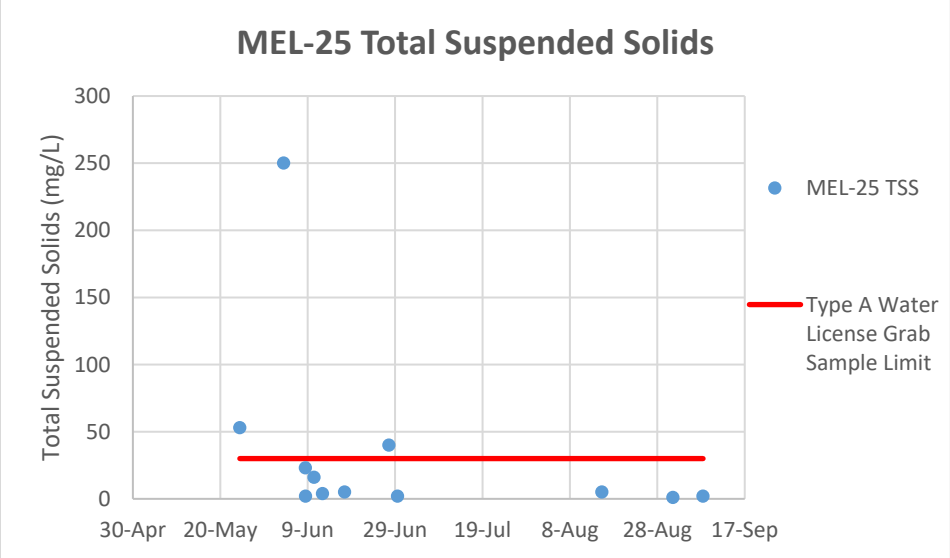
MEL-21 is sampled in lake B8 and will be sampled in CP-4 (collection pond) once construction is completed. CP-4 will consist of the drainage collection from the Waste Rock Storage Facility (WRSF1) located west of the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.11 ***MEL-22 CP-5***

MEL-22 is sampled in CP-5 (collection pond) which consists of the drainage from WRSF1 and WRSF 2. CP-5 previously was lake A54 and is located south of the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.12 ***MEL-23 CP-6***

MEL-23 is sampled in lake H19 and will be sampled in CP-6 (collection pond) once construction is completed. CP-6 will consist of the drainage from WRSF3 located east of the mine site. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.



7.3.1.13 ***MEL-24 Seepage from the landfill***

MEL-24 is seepage from the landfill between the landfill and Pond H3. The natural depression at this location can also drain water not related to seepage from the landfill. It is a verification monitoring location which is sampled for operational and management purposes by Licensee. Monitoring parameters may vary between locations. Monitoring parameters and locations are internal for Licensee.

7.3.1.14 ***MEL-25 Secondary Containment at the Itivia Fuel Storage Facility***

MEL-25 is sampled from the secondary containment area at the Itivia Site Fuel Storage and Containment Facility. It is a regulated monitoring station in the water licence. It includes discharge limits that must be achieved to maintain compliance.

Figure 7.5 TSS results for MEL-25 samples

Two notices for discharge from MEL-25 were sent in 2018 to the appropriate agencies. The first notice was sent on May 24th pending water quality. Due to high TSS results, the discharge was postponed until the maximum average concentration respected for the License requirement was achieved. A total of 2,205 m³ was discharged using a filtration bag for TSS removal. Another notice was sent on August 20th once again pending on water quality. All results met license criteria due to an internal misunderstanding, the water was trucked and discharge in CP-1.

7.3.2 Underground sampling

Water samples collected in 2018 in the underground mine include those taken from DDHs intersecting the fractured rock groundwater network and sumps.

DDH water samples were collected and analyzed for a full suite of water quality parameters to provide a representation of the background “non-contact” groundwater quality, which is the primary contributor of water received by the underground mine. Additional to these samples was the collection of 6 monthly water samples from unique DDHs located in lower elevation zones of the mine within the cryopeg. These samples were analyzed for fish toxicity, measuring LC50 of Gasterosteus aculeatus (Threespine stickleback).

Sump water samples were collected monthly for water quality analysis from level 75 and level 125 of the underground mine. These samples represent a combination of the contact water generated by the underground mine, including groundwater, make-up water, drilling water, and freshet inflow.

Underground mine sampling is a verification monitoring program carried out for operational and management purposes by the Licensee.

The Saline Water Treatment Plant (SWTP) treats water from the underground and was commissioned during the 4th quarter of 2018. Monitoring stations (SWTP-IN and SWTP-OUT) exist at the inlet and outlet to the SWTP. This is a verification monitoring program carried out for operational and management purposes by the Licensee.

7.3.3 QAQC Sampling

The objective of quality assurance and quality control (QA/QC) is to assure that the chemical data collected are representative of the material being sampled, are of known quality, are properly documented, and are scientifically defensible. Data quality was assured throughout the collection and analysis of samples using specified standardized procedures, by the employment of accredited laboratories, and by staffing the program with experienced technicians.

All analytical chemistry analyses are performed by an accredited laboratory. In most cases, these analyses will be performed by Maxxam, an accredited facility located in Ottawa, Ontario. Agnico Eagle may also require the services of other laboratories, such as Maxxam in Edmonton, AB, SGS in Lakefield, ON and H2Lab in Val d’Or, QC. All data from these labs undergoes a rigorous internal QA/QC process, including the use of spiked samples and duplicate samples.

All sublethal toxicity tests were performed by Aquatox in Ontario. Testing was conducted as stipulated in the corresponding Environment Canada Biological Test Methods. QA/QC measures implemented by the lab, including the use of reference toxicants, met the acceptable limits.

Field blanks are treated as a normal sample. They are used to identify errors or contamination in sample collection and analysis. Duplicate field water quality samples are collected simultaneously in the field and used to assess sampling variability and sample homogeneity.

- MDMER and EEM monitoring programs consisted of: 3 duplicate samples and 3 field blanks which were collected from a total of 24 samples, representing 12.5% of samples taken;
- STP monitoring program consisted of: 8 duplicate samples and 8 field blanks which were collected from a total of 54 sampling events, representing 14.8% of samples taken; and
- Surface water monitoring programs consisted of: 24 duplicate samples and 11 field blanks which were collected during the year.

Analytical precision is a measurement of the variability associated with duplicate analyses of the same sample in the laboratory. Duplicate results were assessed using the relative percent difference (RPD) between measurements. The equation used to calculate RPD is:

RPD = (A-B)/ ((A+B)/2)*100; where: A = field sample; B = duplicate sample.

Large variations in RPD values are often observed between duplicate samples when the concentrations of analytes are low and approaching the method detection limit. Consequently, a RPD of 20% for concentrations of field and duplicates samples that both exceed 10x the method detection limit (MDL) is considered notable. The analytical precision of one QA/QC sampling event is characterized as:

- High, when less than 10% of the parameters have variations that are notable;
- Medium, when 10 to 30% of the parameters have variations that are notable;
- Low, when more than 30% of the parameters have variations that are notable.

For field measurements, the following equipment is used:

- Hach Meter (turbidity);
- Oakton PCS35 Meter (pH and conductivity); and
- Eureka Mantha 20+ Meter (pH, dissolved oxygen, temperature and conductivity).

QA/QC methods and results for specific field programs are discussed separately in their respective reports.

7.4 SEEPAGE

As required by Water License 2AM-MEL1631 Schedule B, Item 8*: Summary of quantities and analysis of Seepage and runoff monitoring from the Landfill, Landfarm, Waste Rock Storage Facilities, Borrow pits and Quarries.

In 2018, no seepage was observed from the landfill or the landfarm. The Tailing Storage Facility and the Waste Rock Storage Facility are not built yet and no seepage was observed from borrow pits or quarries

7.5 VISUAL AWAR WATER QUALITY MONITORING

Pre-freshet and freshet inspections were conducted at crossings along the AWAR and the Bypass road at Itivia in 2018. These inspections are conducted to document potential hazards like blockages impeding free flow of water resulting in ponding, washing out of roads and unintentional rerouting of flow, detecting the presence/absence of flow, erosional concerns and turbidity plumes. The clearing of the Char River, Meliadine River and M5 crossing started on May 4th. No issues were observed during the inspections conducted on May 17th, 27th and June 1st and 3rd, 2018. Starting June 6th, some straw logs were installed on the downstream side of the road at km 24 and 28 to prevent TSS migration. Inspections occurred daily from June 9th to June 14th and straw logs were added at km 19 and 22. A sample was taken on June 10th to monitor the water near the Itivia by-pass road. The TSS result was very low, 2 mg/L.

Weekly inspections were also conducted along the AWAR throughout the year. During the freshet and open water season, any visual turbidity plumes or erosion along the AWAR, culverts or bridges are documented by Environmental Technicians. No issue was raised in 2018

7.6 BLAST MONITORING

During the 2017 surface blasting campaign, the mine utilized an Instantel Minimate Pro4 seismograph to record blast vibration. This device was tested in 2018, but due to a technical issue, the device was required to be sent south for repair and calibration. Agnico Eagle then rented two (2) Nomis Mini Supergraph II from Geophysique GPR International Inc. which arrived on site in December 2018. Hence no blast monitoring was able to be completed during 2018 as all blasts were already performed. In 2018, 13 surface blasts occurred (5 at Itivia and 8 at mine site). At Itivia's quarry, blast size were conducted according to the seismograph monitoring conducted in 2017 where no exceedance were recorded. All blast conducted in 2018 used less powder and the blast were smaller in size. For the mine site blast, monitoring started in January 2019. As of March 2019, the average peak particle velocity (mm/s) for Meliadine lake is 3.2, for Lake B5 1.8 and for Lake B7 2.0. These readings are taken from the shore closest to the blast for each lake which is very conservative regarding the exact peak particle velocity in a spawning bed. The average pressure (kPa) for Meliadine lake is 4.14, for Lake B5 2.41 and for Lake B7 2.60. Monitoring for surface and underground blast will continue in 2019 and a monitoring report will be included in the 2019 annual report

7.7 NOISE MONITORING

The objective of the noise monitoring program at Meliadine is to measure noise levels at four previously determined monitoring locations over at least two 24 h periods. In 2018 Agnico Eagle conducted two successful rounds of monitoring for stations NPOR006 and NPOR017, and one successful round of monitoring for NPOR008 and NPOR014. However, high winds (both measured and audible) and frequent bird calls in close proximity to the noise meter substantially reduced the quality of the data for comparison to FEIS predictions.

A summary of the available noise monitoring results is provided in Table 7.3. For station NPOR006 and NPOR017, insufficient valid data was available after initial and/or secondary filtering to calculate 24-h or night-time L_{eq} values. For station NPOR008, only a night-time L_{eq} could be calculated after initial filtering, and the data exceeded the design target of 40 dBA. However, sound recordings were dominated by wind and wave action, and no human-associated activities were audible, so a secondary filtering was not

performed. The calculated L_{eq} value is not considered comparable to FEIS predictions or design targets, which assume limited background noise. Similarly for NPOR014, the measured 24-h and night-time L_{eq} values exceeded noise monitoring criteria and the design target, respectively, but no mine-related activity is ongoing in this area, and sound recordings were dominated by wind, waves, and near-continuous bird calls for significant portions of the dataset.

Table 7.4 Summary of noise monitoring results in 2018

Location	Monitoring Start	Monitoring End	Noise Monitoring Criterion - $L_{eq(24\ h)}$ (dBA)	FEIS Prediction - $L_{eq(24\ h)}$ (dBA)	Measured $L_{eq(24\ h)}$ (dBA)	Measured $L_{eq\ (nighttime)}$ (dBA)
NPOR006	08/22 11:08	08/22 21:44	45	39.8	NA	NA
	09/04 11:38	09/07 16:37	45	39.8	NA	NA
NPOR008	08/28 17:42	08/29 5:53	45	41.7	NA	*64.5**
NPOR014	08/25 16:26	08/28 16:27	45	44.7	*63.5**	*49.9**
NPOR017	08/10 12:07	08/12 23:59	45	43.4	NA	NA
	09/09 10:11	09/09 21:50	45	43.4	NA	NA

"NA" indicates insufficient valid data was available after filtering. *No mine activity is audible at these remote sites, so measured values are assumed representative of baseline; no filtering on the basis of sound recordings was performed.

Overall, a very limited dataset was available for calculation of 24-h and night-time L_{eq} values in 2018. This was generally due to a tendency towards sub-optimal weather conditions, and subsequent filtration of the data. The data collected in 2018 suggests that measured background sound levels in this area may regularly exceed those assumed during the FEIS (35 dBA), likely due to predominant high winds and wave action on the shore of Meliadine Lake. Particular care will be taken in the future to ensure monitoring is conducted when wind speeds are at their lowest, to reduce the significant wind and wave noises contributing to background sounds. Timing monitoring events earlier in the season may also help reduce the frequency of bird calls which were especially dominant in recordings this year, and which consistently contributed to recorded sound peaks. Continued use of a far-field reference station such as NPOR014 will be considered, in order to better define background noise levels in this area.

The following actions were planned for 2018 and responses of Agnico are indicated:

- Additional efforts will be made to conduct monitoring at NPOR006 while the cabin is unoccupied.
    - Attempts were made to fulfill this objective, but the cabin at NPOR006 is regularly occupied and was in use at the time of noise surveys. Agnico will conduct reconnaissance at nearby station NPOR005 (according to the Noise Abatement and Monitoring Plan) in 2019 to determine occupancy rates, and will conduct monitoring at this station if feasible.

The following actions are planned for 2019:

- Noise monitoring surveys will be conducted earlier in the ice-free season when wind speeds and animal interference (bird calls) are minimized.

- Weather data will be reviewed during or immediately following noise monitoring events to estimate the proportion of usable data and the need for supplemental monitoring.
- Reconnaissance and monitoring (if feasible based on occupancy) will be conducted at NPOR005, since high occupancy rates at NPOR006 tend to interfere with assessments of mine-related noise in this location. Monitoring will also be conducted at NPOR006.
- Monitoring will focus on NPOR005, NPOR006, NPOR008 and NPOR017. Since activities at the Discovery Pit are not ongoing, monitoring is not required at NPOR014. However, data will be collected at this station if time and weather conditions permit.

The complete Noise report can be found in Appendix H-4.

7.8 AIR

7.8.1 Air Quality monitoring

Through ambient air quality monitoring program, Agnico Eagle aims to measure airborne particulates, dustfall, and the gaseous compounds (NO_2 and SO_2) using a combination of active and passive sampling methods. In accordance with the Air Quality Monitoring Plan, monitoring in 2018 included analysis of dustfall in seven locations, as well as NO_2 and SO_2 in two locations, over one month averaging periods throughout the year. Active sampling of total suspended particulates (TSP), $PM_{2.5}$, and PM_{10} began in December 2018. Available results for all parameters were compared to regulatory guidelines and Final Environmental Impact Statement (FEIS) predictions, and spatial and temporal trends were assessed.

Dustfall results are compared to Alberta's Ambient Air Quality Guidelines (June, 2016) for recreational and industrial areas, for context. In 2018, 2 of 36 samples exceeded the recreational area guideline (DF-3, 25 m from the All Weather Access Road), but no samples exceeded the industrial area guideline. Results indicate very low rates of dustfall overall, despite elevated traffic compared to FEIS predictions. No quantitative predictions were made for dustfall in the FEIS.

Suspended particulates (TSP, $PM_{2.5}$, and PM_{10}) were analyzed in two locations using Partisol air samplers beginning in December, 2018. All available results were below regulatory guidelines (Government of Nunavut Ambient Air Quality Standards/CCME Canadian Ambient Air Quality Standards /BC Ambient Air Quality Objectives) and were below maximum concentrations predicted in the FEIS.

Calculated annual average concentrations of NO_2 and SO_2 were well below the Government of Nunavut Ambient Air Quality Standards, and were below FEIS maximum predicted values. This was the second full year of monitoring for gaseous compounds, and no clear spatial or temporal trends were observed. As described in the Air Quality Monitoring Plan, a permanent weather station was installed at the Meliadine site, and daily averages for wind speed, direction, temperature, solar radiation, and rainfall are provided.

Since monitoring results in 2018 were within applicable air quality criteria and FEIS predictions, no additional adaptive management measures are planned.

Air quality monitoring discussion for the AWAR is provided in section 10.3. As for onsite air monitoring, during landfill activities such as topping and capping, visual monitoring will occur and if deemed necessary, water will be applied as a mitigation measure for dust. Snowpack survey is planned to be conducted during the 2018-2019 winter. Early 2019, as agreed with a senior engineer from the GN, samples for diesel exhaust particulate underground were completed as an indicator for both acrolein and aldehyde and all samples came back well below the occupational exposure limits. This is a good indication of low concentrations of all other contaminants associated with underground work. Samples will be collected for aldehydes in 2019. Acrolein is very unlikely to be present therefore it is deemed unnecessary to sample for it unless there is some indicator that it may be present in the mine.

The air monitoring full report can be found in Appendix H-5.

7.8.2 Greenhouse Gas Emissions

Estimated greenhouse gas emissions for the Meliadine site as reported to Environment Canada's Greenhouse Gas Emissions Reporting Program in 2018 was 62.05 kt/yr of CO_2e, which is lower than the FEIS maximum predicted emission rate of 304 kt/yr of CO_2e. Estimated GHG emissions from the additional marine operations at Rankin Inlet was approximately 13 kt/yr of CO_2e in 2018 (included in the 2018 total). The estimated greenhouse gas emissions for the Meliadine in 2018 is higher than the value obtained in 2017 (39.48 kt/yr of CO_2e) due to the increased activities on site. This amount is based on the amount of fuel consumed from the project reserves and therefore only project-related traffic is calculated. The amount of fuel oil, diesel, gasoline, explosives and propane are calculated and adjusted with emission factors to transfer in tonnes of CO_2, CH_4 and N_2O. These are combined to give the amount in kt/yr of CO_2e. A Greenhouse Gas Reduction Plan was submitted to the NIRB in 2019 including:

- An estimate of the Project's GHG baseline emissions;
- A description of monitoring measures to be undertaken, including the methods, frequency, parameters, and a description the analysis; and
- A description of reduction initiatives planned and taken, to reduce project-related GHG emissions over the Project lifecycle.

The Greenhouse Gas Reduction Plan can be found in Appendix I-1.

7.8.3 Climate

A permanent weather station was installed at the Meliadine site. The station records monthly data for the average, maximum and minimum temperature, the average and maximum wind speed and the total, daily average and maximum precipitation which can be found in table 7.4.

Table 7.5 2018 Monthly climate data

Date	Temperature Average	Temperature Max	Temperature Min	Wind Speed Average	Wind Speed Max	Total Precipitation	Daily Average Precipitation	Max Daily Precipitation
	°C	°C	°C	m/s	m/s	mm	mm	mm
January	-28.8	-14.6	-37.0	17.4	68.0	7.9	0.25	3.0
February	-35.2	-16.9	-46.8	15.3	58.7	10.6	0.38	3.8
March	-21.6	-4.2	-36.4	17.6	67.7	13.2	0.43	4.6
April	-17.3	1.8	-33.7	20.1	72.0	8.8	0.29	2.8
May	-9.4	1.7	-23.2	22.7	73.6	38	1.23	8.6
June	3.6	17.1	-8.4	16.6	62.4	28.4	0.95	20
July	13.0	27.5	-0.1	15.6	66.9	15.8	0.51	6
August	9.7	20.7	2.0	23.3	88.7	52.8	1.70	16
September	2.2	13.4	-5.8	18.2	70.3	19	0.63	5.4
October	-6.9	2.9	-27.1	17.5	66.5	24.6	0.79	6.8
November	-21.8	-1.0	-37.9	16.8	54.8	19.6	0.65	9.2
December	-24.6	-7.2	-38.4	15.4	61.0	8.6	0.28	2.2

7.9 WILDLIFE MONITORING

All Meliadine employees and contractors are required to report wildlife sightings. All supervisors ask their employees to report wildlife sightings; wildlife logs are posted throughout the Meliadine camp and are easily accessible to employees to facilitate wildlife reporting after work shifts. All observations, problematic interactions, wildlife surveys conducted weekly along the AWAR, caribou migration, operation shut downs related to caribou migration, aerial observations when helicopters are active, onsite audits (i.e for wildlife attractants) conducted by third parties, and mitigation actions taken following problematic issues are reported in the monthly report to the Government of Nunavut, the Kangiqliniq Hunters and Trappers Organization and Kivalliq Inuit Association. Department toolbox meetings were completed in 2018 for environmental subjects including wildlife and caribou migration. The presentation and the attendance sheets can be found in Appendix F1

7.9.1 TEMMP

In 2018, Agnico Eagle retained Golder Associates to undertake the wildlife and vegetation monitoring programs, in accordance with the Terrestrial Ecosystem Monitoring and Management Plan (TEMMP). The purpose of this report is to summarize the 2018 data collected from wildlife and vegetation monitoring programs, and to describe natural variation and potential mine-related changes in wildlife populations within and adjacent to the Mine. The 2018 report describes monitoring objectives and methodology, 2018 annual results, mitigation activities, and management recommendations based on 2018 monitoring results. Below is a summary of the monitoring/findings from the 2018 TEMMP. Full text of the 2018 annual TEMMP report can be found in Appendix H-6.

Incorporation of Inuit Quajimajatuquangit

When possible, field programs in 2018 were guided by Inuit Qaujimajatuqangit (IQ), including the assistance of local field assistants.

Direct Habitat Loss

In 2018, a total area of 484 ha has been altered due to Project construction, representing 29% of the Predicted Project footprint (1,682 ha). Of the total project impacted habitat, 343 ha is vegetated heath types (36% of the predicted impacts), 95 ha is wetland riparian types (22% of the predicted impacts) and 6 ha of un-vegetated sand community (75% of predicted impacts).

The project has altered 46 ha of unvegetated areas, representing 16% of the Predicted Project footprint. Of these, 40 ha (14% of the predicted project footprint) are associated with waterbodies and watercourses

Indirect Habitat Loss

Indirect habitat loss for caribou and wildlife habitat (soils and vegetation) was not assessed in 2018.

Wildlife Observations

Between 4 January and 27 November there were incidental observations of 13 different species and over 214 observations of approximately 7,187 individual animals.

Wildlife Track Surveys

On-site wildlife track surveys were conducted on November 3rd and 23rd and on December 8th, 15th and 25th. All observations were limited to arctic fox and hare tracks - no caribou tracks were observed. A predatory mammal observation report was completed for wolf tracks which were observed on the main camp site on April 10th and for two polar bears observed on November 10th.

Nest Relocation

In July, an active Common Redpoll nest was observed within an active construction zone. A Damage or Danger Permit was issued under the Environment Canada Migratory Birds Regulations (MBR), which authorized the relocation of the migratory birds, eggs (3) and nest. The nest and eggs were successfully relocated, allowing the birds to fledge.

Incidents and Mortalities

A gosling was found deceased near the Meliadine Lake gen set area. It is believed to have died on the lake of unknown causes and was brought to shore through wave action. A total of 22 arctic foxes were trapped and dispatched by GN DoE officers in 2018

Wildlife Deterrents

Bird deterrent canons were initially deployed on P1 and P3 dykes on June 21, 2018. Shortly after deployment, a deterrent canon was moved to the landfarm at the request of the NIRB. Concerns were raised about the canons impacts on caribou and other wildlife at which point canons were removed on July 2nd. Other deterrent (snow owls and predatory birds kites) will be monitored in 2019. No wildlife deterrents were used to deter caribou in 2018.

Barren-ground Caribou

Caribou Advisory

Mass migration through the Project and AWAR took place between 5 July and 22 July 2018. The caribou work suspension protocol (complete work stoppage) was in effect for periods from 8 July to 17 July. Closure and restrictions on AWAR took place on 7-20 July. There was a complete work stoppage for 191 hours and restricted duties for 93 hours in 2018 (Mine and AWAR).

Caribou Behavior

Caribou behavior observations were completed on seven groups of caribou in 2018. Observations showed no obvious behavioral response to mine activity.

Hunter Harvest

A Memorandum of Understanding (M.O.U.) was recently signed with the Rankin Inlet KHTO and involved the hunter harvest studies.

Birds

Shoreline Surveys

All waterbodies within 200 m of mining related infrastructure (excluding the AWAR) were surveyed on foot by trained biologists to locate and identify nesting waterbirds from June 12th to 18th. A total of eight different species were observed. No fledglings were observed, all observations were nesting adults, and eggs observed in nests. In total, 56 adult birds were recorded with 27 eggs observed among eight different species. Waterbodies within 200 m of the AWAR were not completed due to time constraints.

Point Counts

Avian point count locations were chosen to be within 1 km on either side of the AWAR (2 km in total) with the first point counts occurring at 50 m from the road on either side, with subsequent plots spaced 100 m from the preceding plot. A total of 6 transects were completed for a total of 72 point count surveys. The survey method is described in more detail in the TEMMP (Golder 2015).

In total, seven passerine (i.e. songbird) species were recorded on the point count surveys. The most abundant species was horned lark (*Eremophila alpestris*) and the least abundant species was American robin (*Turdis migratorius*).

PRISM

Agnico Eagle contributed to the Environment and Climate Change Canada (ECCC) PRISM surveys in 2018 and will continue to do so every three years. For the 2018 surveys, a representative from ECCC, Golder biologists, and two local assistants completed PRISM surveys at the Project at randomly chosen locations (by ECCC). Observers recorded the species encountered, estimated their breeding status, and recorded habitat conditions. A total of ten PRISM survey plots were surveyed with a total of fourteen bird species observed. The most common bird species observed in the plots were Lapland longspur (*Calcarius lapponicus*), savannah sparrow (*Passerculus sandwichensis*) and horned lark (n=6). No species-at-risk were observed on survey plots. Breeding evidence of three species of shorebirds was found during the surveys. Due to the late spring in 2018, and the relatively early timing of the field work, no actively nesting songbirds were found during PRISM surveys.

Soil and Vegetation Monitoring

Invasive Plant surveys were completed along the AWAR and Project footprint. Two occurrences of common dandelion were recorded along the AWAR. Common dandelion was not observed in the Project footprint or ship loading areas.
Soil and vegetation contamination (metals and dust) will be monitored in 2019.

Environmental Variables

The max annual temperature of 27.5°C was recorded on July 11, 2018 and the minimum annual temperature -46.8°C was recorded on February 19, 2018. Snowmelt began June 9, 2018 when the average daily air temperature exceeded 0°C. Environmental variables will continue to be monitored on an on-going basis.

7.9.2 Marine Environment

A Marine Mammal and Seabirds Observation (MMSO) report was completed for all observations done during the 2017 and 2018 sealift season. The purpose of the MMSO program is to mitigate interactions between marine mammals and seabirds and Project vessels and to collect information on marine wildlife presence. This report provides an interpretation and discussion of the MMSO data collected in 2017 and 2018 by the shipping contractor Transport Desgagnés.

In 2018 the marine mammal observations were conducted from the Acadia Desgagnés. Marine mammal observations were reported between 26 June to 24 July 2018. There were no marine mammals observed in 2018. A maximum of 12 seabird species were recorded during moving and stationary platform surveys in 2018 (June to October). The density of seabirds reported was generally low, although densities estimated from 2018 moving platform data were significantly higher than in 2017. No marine mammal-vessel interactions or birds-vessel interactions (e.g., strikes) were recorded in 2018. The complete report can be found in appendix H-7.

7.10 ARCHAEOLOGY

In 2018, Agnico Eagle requested Golder to provide updated information in years that changes have occurred to the Meliadine Gold Project (Project) footprint. In 2018, a Nunavut Archaeologist Permit was issued to Golder. The assessment focussed on examining expansion to the Meliadine East Esker borrow pit located north of Lake H17, as well as baseline studies for potential infrastructure under consideration. No issues were raised, recommendations were made to continue avoidance by 30 meters buffer for some sites. The memo from the assessment can be found in appendix H-8.

7.11 VEGETATION

On June 1, 2018 Agnico Eagle Mines and the University of Saskatchewan were successful in receiving a Natural Sciences and Engineering Research Council (NSERC) Collaborative Research and Development grant. The grant entitled “Tundra Restoration: Niche construction in early successional plant-soil systems” will support on-site and laboratory research from June 2018 to June 2022. The primary objective of this research is to address Term and Condition no. 41 of the Project Certificate for the Meliadine site: “Prior to the commencement of operations, the Proponent shall develop a progressive re-vegetation program for disturbed areas that are no longer required for operations, such program to incorporate measures for the

use of test plots, reseeding and replanting of native plants as necessary." The specific objective is the characterization of initial and realized niches of biological soil crusts and tundra vascular plants across a chronosequence of naturally recolonized drilling waste dumps. This work was completed during the 2018 summer.

A total of 25 drilling waste sites were examined across a range of ecotypes including low-lying hummock-hollow complexes dominated by sedges, upland hummock-hollow complexes dominated by heath and upland lichen-heath often with frost boil features. Following delineation of each drilling waste site, a transect was placed along the long axis of the waste site and three survey plots (1 m^2) were placed at the center of this transect. In addition, at each site a control transect was placed at least 10 m from the edge of the drilling waste and three adjacent 1 m^2 plots were placed in undisturbed vegetation of the same type, slope and aspect as the disturbed area. The percent cover of all vegetation species present was estimated by eye and the drilling waste and organic matter depth was measured in the center of each plot.

It was found that natural revegetation of drilling wastes is occurring at the Meliadine site. The community composition between drilling wastes and the paired undisturbed tundra was similar 20-25 years post disturbance and species richness recovered within 6 years. Due to the different life history characteristics of tundra plants, individual species responses to disturbance were observed. While sedges and mosses may recover more rapidly on these drilling wastes, dwarf shrubs and lichens may require longer to recover. These trends in natural recovery are important for guiding future restoration efforts and techniques. Specifically, targeting sedge and moss species for transplanting and/or seeding of disturbed substrates may be a highly effective strategy for initiating the development of early successional tundra communities.

Based on the findings, suggestions to improve and/or maintain the relatively rapid natural revegetation of the drilling wastes was provided: i) Placement of drilling wastes on the landscape that allow for remnant patches or islands of intact tundra throughout the disturbed area; ii) Apply drilling wastes in thin layers to allow for vegetative establishment; and iii) Promote establishment of bryophyte communities in the early stages of revegetation to support long-term ecosystem recovery.

Given the findings of this study it is suggested that active restoration of the drilling wastes is likely not required for the recovery of the tundra plant communities, if the timeline for recovery is ~20 years. Therefore, in the on-going work to develop tundra restoration techniques, it is suggested to develop active restoration trials at other disturbed areas on the Meliadine site during the 2019 summer.

The complete report can be found in Appendix I-1. More information regarding the vegetation can be found in the TEMMP report in Appendix H-6

SECTION 8. CLOSURE

8.1 PROGRESSIVE RECLAMATION

8.1.1 Mine Site

As required by Water License 2AM-MEL1631 Schedule B, Item 15: ***A summary of any progressive closure and reclamation work undertaken including photographic records of site conditions before and after completion of operations, and an outline of any work anticipated for the next year, including any changes to implementation and scheduling.***

And

As required by Water License 2BB-MEL1424 Part B, Item 6k: A description of all progressive and/or final reclamation work undertaken, including photographic records of site conditions before, during and after completion of operations;

Construction was underway at Meliadine in 2018, no progressive closure or reclamation work was undertaken during the year on the mine site.

8.1.2 AWAR

No progressive closure or reclamation work was undertaken during the year on the AWAR.

8.1.3 Quarries

In 2018, reclamation work occured at the Itivia quarry. Agnico Eagle proceeded to the reclamation according to the quarry conditions by removing all equipment and material, stabilizing and gently sloping the walls. Once the reclamation work was completed, a GN Regional Lands Administrator and a Hamlet foreman inspected the quarry and confirmed that they were satisfied with the current state of the Itivia quarry site. No other reclamation occurred in 2018.

8.2 RECLAMATION COSTS

As required by Water License 2AM-MEL1631 Schedule B, Item 17: ***An updated estimate of the current restoration liability based on project development monitoring, results of restoration research and any changes or modifications to the Appurtenant Undertaking.***

And

As required by Water License 2BB-MEL-1424 Part B Item 6h: An updated estimate of the current Meliadine West Gold Project restoration and liability, as required under Part B, Item 3, based upon the results of the restoration research, project development monitoring, and any modifications to the site plan;

A permanent closure and reclamation financial security cost estimate was prepared in March 2014 using the RECLAIM model, version 7.0. According to that estimate, the closure and

reclamation of all Project facilities amounted to $47,449,337. This estimate was included in the Preliminary Closure and Reclamation Plan (April 2015) prepared as part of the Type A Water License application. In negotiations between CIRNAC, Agnico Eagle and KIA the quantum of security was increased to $49,555,000.

On July 1, 2017, the Production Lease KVPL11D01 between KIA and Agnico Eagle came into effect; the security was confirmed at $49,555,000. Agnico Eagle posted a Reclamation Security Deposit, equal to 50% of this estimate ($24,777,500) with KIA.

In 2019 , an Interim Closure and Reclamation Plan will be prepared in accordance with the Mine Site Reclamation Guidelines for the Northwest Territories, 2007 and consistent with the CIRNAC Mine Site Reclamation Policy for Nunavut, 2002. An updated reclamation cost estimate, using the CIRNAC RECLAIM Reclamation Cost Estimating Model (Version 7.0 or the most current version at the time the updated reclamation cost estimate is submitted to the Board) will also be completed in 2019.

SECTION 9. STUDIES/REVISIONS/MODIFICATIONS

9.1 SUMMARY OF STUDIES

As required by Water License 2AM-MEL1631 Schedule B, Item 18: ***A summary of any studies requested by the Board that relate to Water use, Waste disposal or Reclamation, and a brief description of any future studies planned.***

And

As required by Water License 2BB-MEL1424 Part B, Item 6l summary of any specific studies or reports requested by the Board, and a brief description of any future studies planned or proposed;

No studies were requested by the NWB in 2018.

However, Agnico Eagle in partnership with the University of Saskatchewan started a tundra revegetation/restoration study in the summer of 2018. Both past mineral exploration drilling and proposed operations have and will impact the tundra environment at Meladine; with over 3000 drilling sites in the regional area and further drilling and mine site development expected, there is a strong need for site-specific tundra restoration techniques. Seeding and fertilization is commonly used in many revegetation efforts.

With the objective to eventually discharge excess groundwater effluent into Melvin Bay, Golder was retained by Agnico Eagle to conduct marine environmental reconnaissance surveys in Melvin Bay to establish appropriate reference areas and collect preliminary baseline data on physical properties of the water column, water and sediment quality, benthic substrate, benthic communities and marine mammal occurrence.

9.2 SUMMARY OF REVISIONS

As required by Water License 2AM-MEL1631 Schedule B, Item 19: ***Where applicable, revisions will be completed as Addendums, with an indication of where changes have been made, for Plans, Reports, and Manuals.***

And

As required by Water License 2BB-MEL-1424 Part B Item 6g: Any revisions to the Spill Contingency Plan, Site Water Management Plan, Used Water Management Plan, Waste Management Plan, Waste Rock and Ore Storage Plan, Landfill and Landfarm Management Plans, Abandonment and Restoration Plan, as required by Part B, Item 12, submitted in the form of an Addendum;

The following monitoring and management plans were created or updated and are include in Appendix I-1:

- Analysis of Risk of Temporary Closure
- Greenhouse Gas Reduction Plan
- Natural Recovery of Tundra Vegetation Following Exploration Drilling at Meliadine

- Shipping Management Plan
- Wildlife Protection and Response Plan
- Oil Pollution Emergency Plan
- Environmental Management and Protection Plan
- Landfill Waste Management Plan
- Landfarm Management Plan
- Freshet Action Plan (appended to Water Management Plan)
- Incineration Management Plan
- Mine Waste Management Plan
- QAQC plan
- Road Management Plan
- Dust Management Plan
- Sediment and Erosion Management Plan
- Spill Contingency Plan
- Groundwater management Plan
- Water Management Plan
- Water Quality and Flow Monitoring Plan

9.3 MODIFICATIONS

As required by Water License 2AM-MEL1631 Schedule B, Item 12: ***A summary of modifications and/or major maintenance work carried out on all water and waste related structures and facilities.***

And

As required by Water License 2BB-MEL-1424 Part B Item 6e: ***A summary of modification and/or major maintenance work carried out on the Water Supply Facilities, Bulk Fuel Storage Facility, Bermed Fuel Containment Facilities, and Wastewater Treatment Facility, including all associated structures, and an outline of any work anticipated for the next year***

No modifications and/or major maintenance work was carried out on water supply facilities and waste related structures and facilities. However, Agnico Eagle requested in 2018 the approval from the Nunavut Water Board (NWB) to keep the snow cell as a temporary structure until the decommissioning of the P-area is completed which was approved.

SECTION 10. OTHERS

10.1 ACTIVE PERMITS

Below is the list of all active permits and authorizations for Meliadine

Table 10.1: List of all active permits and authorizations for Meliadine

Issued By	ID	Description	Issue	Expiry
KIA	KVPL11D01	Production lease	2017/06/30	2029/06/30
KIA	KVCA07Q08	Tiriganiaq/Westmeg/Meliadine quarry permit	2016/09/12	2021/09/12
KIA	KVCA11Q01	Exploration road quarries	2015/08/31	2021/04/19
KIA	KVRW11F02	Exploration road right-of-way	2012/04/19	2027/06/29
KIA	n/a	Water Compensation Agreement	2016/02/11	2031/03/31
NWB	2BB-MEL1424	Bulk Sampling and exploration drilling water license	2009/07/31	2024/07/21
NWB	2AM-MEL1631	Mining undertaking water license	2016/04/01	2031/03/31
NIRB	006	Project certificate	2015/02/26	N/A
NIRB	16QN071	Screening decision (Itivia Quarry)		
GN-NAD	102631	Land lease, laydown Itivia		2021/07/01
GN-CGS	01-600-18	Quarry permit - site D	2017/03/22	2019/05/01
GN-CGS	01-600-21	Quarry permit - site D	2017/05/01	2019/08/01
GN-CGS	L-51809T	Right-of-Way permit AWAR on Municipal land	2017/06/01	2027/05/31
GN-CGS	L-51808T	Right-of-Way Lease Bypass Road km 2-7	2017/06/01	2027/05/31
GN-NAD	102893	Right-of-way lease bypass road km 1-2	2017/07/01	2027/07/01
GN-ENV	2018-058	Wildlife Research Permit	2018/10/01	2019/09/30

10.2 INSPECTIONS

As required by Water License 2AM-MEL1631 Schedule B, Item 21: ***A summary of actions taken to address concerns or deficiencies listed in the inspection reports and/or compliance reports filed by an Inspector.***

Table 10.2: Inspections and site visits by regulators

Month	Authority	Topic	Feedback/Outcome
Feb 2nd and 5th	CIRNAC, KIA, ECCC	Spill follow up from the exploration camp sewage treatment plant	Lab results were requested and provided by Agico Eagle
May 22nd	CIRNAC	Inspection of the Itivia site and bypass road construction	Inspection report with observations, no non-compliance
May 25th	CIRNAC	Inspection of the Itivia site and surface water management	Observations, no non-compliance
June 6th, 7th and 8th	CIRNAC	Inspection for activities at site related to the Nunavut Water Board Water Licence No. 2AM-MEL1631 and 2BB-MEL1424.	Inspection report requesting a response regarding two failures to comply. Response was sent to the inspector.
July 11	CIRNAC	Inspection of the bypass road and Itivia site	Observations, no non-compliance
July 18th	TC	Inspection of the Itivia site and audit emergency spill response equipment, training and regulatory compliance.	The OPEP document was emailed to Philip Levesque at Transport Canada and a hard copy was placed at the Itivia site office, as requested
August 17th	NIRB	Inspection of the Meliadine and Itivia sites, to assess compliance with NIRB project certificate 006	Inspection report with comments and recommendations, comments were addressed, no non-compliance
September 11th	KIA	General overview of the site	No deficiencies
September 19th	TC, TDG	Site inspection and document validations	All requested documents were provided, no non-compliance
September 20th, 21st	CIRNAC and ECCC	Inspection for activities at site related to the Nunavut Water Board Water Licence No. 2AM-MEL1631 and 2BB-MEL1424.	Inspection report with observations, observations were addressed, no non-compliance

10.3 AWAR

The traffic volume to date exceeds what was expected and stated in the FEIS. As a result, there has been an increased emphasis put on safety when travelling on the road. This includes required radio communication when approaching “blind hills” and when smaller vehicles such as pickups are approaching larger vehicles including road maintenance equipment, transport trucks, buses, etc. In addition, AEM requires smaller vehicles to pull over when large vehicles are approaching. Speeding on the AWAR is not tolerated. As a result, in 2018, there were no safety issues brought forward to Meliadine management. A meeting was held in Rankin Inlet with the community regarding the safety rules on the AWAR and this will be done every year to increase awareness.

Agnico Eagle would also like to clarify that the proposed ATV/snowmobile detour trail is being considered however, it is still in the planning phase. In 2018, there were 1944 users of the AWAR for traditional activities recorded which correspond to 8 % of the 24,870 total users of the AWAR.

In 2018 actual traffic exceeded predicted under Road Management Plan (RMP) and FEIS by 94% and 84% respectively. Construction at Meliadine is underway, which involves large movement of material, fuel and personnel.

Despite higher than anticipated traffic volume, no exceedances of Alberta’s Ambient Air Quality Guidelines (June 2016) for industrial areas occurred for any sample location. These results indicate low rates of dustfall overall, as discussed in Air Quality Monitoring Report in Appendix H-5.
In 2018, water, Dust Stop and calcium chloride were used as dust suppressants on the AWAR. AEM visually monitored the road to study the effectiveness of the products and observed better results with the usage of calcium chloride. Dust Stop required special equipment for application that was not available at the time the dust suppression was required. Agnico notes that there were no quantitative predictions made in the FEIS however, it is AEM’s intent to continue applying dust suppressant (calcium chloride or other products) on the AWAR and on roads associated with vehicular traffic related to the mine site including applicable roads in Rankin Inlet. Dust suppressant was applied to the entire length of the AWAR beginning on July 30, 2018. AEM interprets these results as a positive effect of the use of calcium chloride as a dust suppressant. The daily log for AWAR users can be found in Appendix J-1.

As requested by the NIRB, Agnico Eagle and the Hamlet met on February 20th to discuss about the signage, dust suppression and the plan for working together in 2019.

The Hamlet feels at this time that the signs are sufficient on the road, there are signs on the bypass road indicating it’s a private road. The roads under the control of the Hamlet will have signs put up by the Hamlet if they feel it is appropriate. Agnico Eagle is looking at the possibility to add signs, one at the gatehouse to inform if the AWAR is open or close and also signs with emergency numbers.

With the bypass road being built and used, the Hamlet feels that the traffic/dust issues that previously occurred should be mitigated. They did indicate that they still expect to get dust complaints but since Agnico Eagle will be using the bypass road the complaints should be less and the dust being generated from the road around Nipissar Lake will be there responsibility. A discussion occurred around the dust suppression on the bypass road. Agnico Eagle indicated that Calcium Chloride could not be used because community members were concerned for potential impact on Nipissar Lake. The Hamlet

indicated that they would have more concerns regarding dust on the Bypass road than getting calcium chloride in Nipissar Lake because of the distance in between the Bypass road and Nipissar Lake. The Hamlet has purchased some dust control equipment and at this point they do not feel they need any assistance from AEM. That may change if they have issues with their equipment. AEM has agreed to provide support if they can. At this point the Hamlet does not require assistance.

Table 10.3: Project-related and non project-related vehicles counts on AWAR

Month	Project related-vehicles on AWAR	Non project-related vehicles on AWAR	Total traffic
January	1146	10	1156
February	1203	0	1203
March	940	4	944
April	946	5	951
May	1361	8	1369

December	1405	839	1178
Total 2018	24870	12831	13538

10.4 MARITIME TRANSPORTATION

In 2018, 2 marine-based fuel transfers occurred at Rankin Inlet related to the Meliadine project. The first one occurred from July 27th to July 29th and the second one between October 10th and 18th. Both events occurred when the Melvin Bay was free of ice and the weather was not a risk to the activity The shipping related to the Meliadine project, including the boats and dates, can be found in table 10-5. No incident was reported during the 2018 maritime transportation.

SECTION 11. PUBLIC CONSULTATION

As required by Water License 2AM-MEL1631 Schedule B, Item 22: ***A summary of public consultation and participation with local organizations and the residents of the nearby communities, including a schedule of upcoming community events and information sessions.***

And

As required by Water License 2BB-MEL1424 Part B, Item 6m: A summary of public consultation/participation, describing consultation with local organizations and residents of the nearby communities, if any were conducted;

11.1 COMMUNITY MEETINGS IN CHESTERFIELD INLET

Agnico Eagle conducted its annual community meeting in Chesterfield Inlet on September 17, 2018, in which Hamlet representatives and Chesterfield Inlet HTO were involved. Agnico Eagle collected the following concerns and Inuit Quajimajatunqangit from the meeting:

- Migration patterns of the caribou herds were being affected by the noise of the barges
- There are less seals than in the past, possibly due to shipping traffic
- Concerned about oil spills and the clean-up protocol
- Concerned about compensation (ex. wildlife fatality) and distribution of benefits from the mine

In order to continue to address these concerns, the following outcomes were decided upon:

- The shipping company Desgagnes will share environmental logs with the Hamlet and Chesterfield Inlet HTO
- Possibility of having a wildlife monitor on board from Chesterfield to Baker Lake
- More detailed information on number of barge trips to be provided

Additionally, as part of the Inuit Workforce Barriers Study (IWBS), interviews were conducted with Elders in Kivalliq communities. In Chesterfield, Elders voiced similar concerns about environmental and marine life impact as listed above.

11.2 COMMUNITY MEETINGS IN RANKIN INLET

Agnico held a community meeting in Rankin Inlet on June 13th, 2018 focusing on the AWAR and included discussions on safety rules, procedures to access road, wildlife and road closure. Additionally, Agnico Eagle held a meeting specifically on the diffuser project on March 18th, 2018.

In 2018, Agnico Eagle started its work towards International Cyanide Management Code (ICMC) certification. As part of that work, Agnico Eagle held a community meeting on August 30th, 2018 on cyanide use, management and transportation.

More details regarding Community meetings can be found in in the Appendix K-1.

11.3 MEETINGS WITH RANKIN KHTO

In 2018, four (4) meetings were held with the Rankin Inlet KHTO. General topics included wildlife monitoring and sediment control, however the focus in 2018 was working to establish a funding agreement with the KHTO. This funding agreement is intended to develop a collaboration that results in the capacity building of KHTO staff to undertake research, monitoring and analysis of wildlife, through the development and implementation of hands-on skill development and theory-based training. Additionally, it creates a Wildlife Coordinator position within the KHTO which participates in monitoring activities at the Projects. The funding agreement is expected to be finalized in 2019.

The Hunter Harvest Agreement is incorporated into the funding agreement with the KHTO. A work plan is expected to be established in 2019.

11.4 COMMUNITY LIAISON COMMITTEE MEETINGS

In 2018, Agnico Eagle continued to attend meetings with the Meliadine Community Liaison Committee in Rankin Inlet, which was established to inform stakeholders on the activities at the mine and to consult them on specific issues and projects.

The Community Liaison Committee's objective is to favour dialogue and exchange between Agnico Eagle and its local stakeholders such that all parties gain a better understanding of the issues associated with mining activities and provides a venue for stakeholders to provide advice to Management for solutions. The Committee is currently facilitated and chaired by the Hamlet of Rankin Inlet as a specific working group of the hamlet, and does sometimes include representation from various groups and organizations, however Agnico Eagle will look at establishing its own Community Liaison Committee in 2019 to ensure that groups such as Elders, youth, Hunters and Trappers Organizations, RCMP, etc. are regularly consulted on the operations. Agnico Eagle would continue to participate in the hamlet's working group.

Meetings are scheduled quarterly in both English and Inuktitut, with the understanding that the minimum number of meetings is two (2) annually. In 2018, three (3) Community Liaison Committee meetings were held.

11.5 ELDERS

In 2018, as part of the Inuit Workforce Barriers Study (IWBS), interviews were conducted with Elders in Kivalliq communities on a variety of topics. Feedback was incorporated into the recommendations of the IWBS.

11.6 SITE TOURS FOR RANKIN INLET RESIDENTS

Each year, Agnico Eagle offers a variety of ways for the residents of Rankin Inlet, as well as various other groups or individuals from the Kivalliq, to visit Meliadine site. The list below outlines the major visits to the site during 2018:

- Agnico Eagle invited residents of Rankin Inlet to come on a site tour. On October 20, 2018, Agnico Eagle organized the regular tour for residents with five (5) buses from Rankin Inlet. Concurrently, Agnico Eagle held a contest and a group of residents were invited to do an underground tour additional to the regular site visit.
- On November 9, 2018, Agnico Eagle also welcomed a group of high school students on site to do a tour and receive a presentation on job opportunities.

More details on site visits in 2018 are summarized in the Appendix K-1.

11.7 COMMUNITY ENGAGEMENT INITIATIVES

Community initiatives that Agnico Eagle participated in during 2018 are summarized in the Appendix K-1.

11.8 COMMUNITY COORDINATORS PROGRAM

The Community Coordinators program consists of full or part-time Agnico Eagle Coordinators in all Hamlets in the Kivalliq Region, including in Agnico Eagle's offices in the communities of Rankin Inlet and Baker Lake.

The objective of the community-based Agnico Eagle Coordinators is to provide a point of contact in each community to facilitate communications, provide services, and coordinate activities in the following areas:

- Support to the HR department by:
    - Assisting HR and other Agnico Eagle departments to locate employees or potential employees as required;
    - Contact employees in advance of their shift departure times;
- Support to the Recruitment team by guiding interested individuals in the application process outlined by the Labour Pool Process;
- Provide advice and assistance to Agnico Eagle to organize and hold information sessions in the community on Agnico Eagle projects and initiatives, including those Labour Pool and business opportunities initiatives outlined in the Meliadine IIBA;
- Provide updates to the Hamlet Council on Agnico Eagle activities; and
- Distribute Agnico Eagle information and promotional materials.

The increase of community involvement requirements for Agnico Eagle to achieve recruitment goals and the obligations for the NIRB and IIBA renders the Community Coordinators essential for Agnico Eagle's Nunavut operations.

11.9 COMMUNICATION

In 2018, Agnico Eagle launched a facebook page for Meliadine which acts as another method with which it can inform the Kivalliq communities of important information, including road closures, recruitment information, and public meetings. This additional medium of communication was suggested by multiple stakeholder groups, including the Kivalliq Socio-Economic Monitoring Committee.

SECTION 12. SOCIO ECONOMIC

The Socio-Economic Monitoring Report (SEMR) is the annual report on the SEMP. It is a comprehensive socio-economic monitoring report that contains Project-level data (data collected by Agnico Eagle at each Project site or regionally) and community-level data (data provided by or in communities), including those data that are mandated by the Project Certificate. It is reviewed by both the SEMWG and the KvSEMC prior to its submission, to allow for those groups to provide insight or data. It is submitted to NIRB on or by June 30 annually as per the SEMWG Terms of Reference. The 2017 SEMR was submitted to NIRB on July 4, 2018 and can be found in Appendix M-1.

The section below represents a subset of Agnico Eagle's socio-economic reporting, related primarily to employment and training. For the full report on the Project's socio-economic monitoring, including those monitoring requirements of Agnico Eagle's Project Certificates for the Meliadine Project, please refer to the 2018 Agnico Eagle Kivalliq Projects Socio-Economic Monitoring Report, which will be submitted to NIRB on or by June 30, 2019.

Reports can also be viewed on the Socio-Economic Monitoring Committee website www.nunavutsemc.com or on Agnico Eagle's website http://aemnunavut.ca/media/documents/.

12.1 WORKFORCE

Agnico Eagle calculates the workforce based on headcount (snapshot of active employees taken at the end of the year, which includes full-time and part-time employees) and full-time equivalents (number of full-time positions based on hours worked, where one full time position is equivalent to 2,184 hours worked in a year).

The number of active Agnico Eagle employees working at Meliadine on December 31, 2018 was 488, of which 62 employees were Inuit employees. (The respective full-time equivalencies were 363 Agnico Eagle employees in total, with 45 full-time (FTE) Inuit Agnico Eagle employees).

The number of contractors employed at the project is only calculated using full-time equivalents (FTEs) due to the cyclical nature of contractor work. Therefore, during 2018 there were 736 full time equivalent (FTE) contractor positions.

Taken together, there were 1,224 active employees (Agnico Eagle permanent, temporary, on-call, students and contractors), working full- and part-time jobs, at the end of 2018.

Agnico Eagle defines job statuses as follows:

- Permanent employee: an employee whose current job is not specifically tied to a short-term project and the position is expected to be required throughout the life of mine (LOM).

- Temporary employee: an employee whose current job will not continue beyond a specified period of time.

- On-call employee: an employee who has an undefined contract and is called upon when the need arises. It is expected that on-call employees will move to temporary or permanent positions as they become available.

12.1.1 Employment Demographics for Nunavut Based Employees

The following tables shows the employment demographics for community of hire by headcount and full-time equivalents.

Table 12.1: Home communities of Agnico Eagle Inuit employees (by headcount)

Community of Hire	2017 Agnico Eagle headcount	2018 Agnico Eagle headcount
Arviat	2	5
Baker Lake	1	5
Naujaat	0	2
Rankin Inlet	14	31
Chesterfield Inlet	1	2
Whale Cove	0	1
Coral Harbour	3	7
Outside of Kivalliq	3	9
Total	**24**	**62**

Table 12.2: Home communities of Agnico Eagle Inuit employees by FTE

Community of Hire	2017 Agnico Eagle FTE	2018 Agnico Eagle FTE
Arviat	1	3
Baker Lake	1	4
Naujaat	0	1
Rankin Inlet	11	23
Chesterfield Inlet	0	2
Whale Cove	0	0
Coral Harbour	1	5
Outside of Kivalliq	1	7
Total	**15**	**45**

Agnico Eagle pays for the transportation of all Kivalliq-based employees from their home community to the mine for each work rotation. For employees coming from Arviat, Chesterfield Inlet, Rankin Inlet and/or Whale Cove, Agnico Eagle has a service contract with Calm Air to transport employees by charter plane to Rankin Inlet. For employees coming from Coral Harbour and/or Naujaat, a commercial ticket is bought from their home communities to the Rankin Inlet airport. All employees are then driven by bus to site. For all other employees not located in the Kivalliq region, transportation is provided from Mirabel and Val-d'Or via a charter flight operated by Nolinor Aviation.

12.1.2 **Employee retention**

Based on Agnico Eagle's past experience and testimonies of former employees, it was noted that many Inuit have never had full time work in their home communities, where full time employment opportunities are potentially limited. Many such individuals want a job, but working away from home for two weeks at a time in a structured industrial environment is a change that many have difficulty adapting to.

Exit interviews support this assumption and the following provides the most common reasons given for voluntary terminations and turnover rates:

- Found another job
- Conflict with employee
- Does not like the job
- No babysitter
- Family situation

Agnico Eagle developed a new approach and has rolled out new initiatives with a focus on providing information, skills, and education to job applicants to ensure that they are better informed about what working life is like at a remote mine site, and to be better prepared to adapt, cope, and be successful in employment. The result is the development and implementation of a Labour Pool Program that consists of a linked series of activities, including:

- Community-based information sessions
- Community-based Work Readiness training
- E-learning for mandatory training
- Site Readiness training at Meadowbank
- On-Call Contract Program (optional)
- Employment with Agnico Eagle or contractors

The Labour Pool Program consists of a suite of activities that provide future employees with information, skills, and education for working life and conditions in a remote, fly in/fly out, industrial workplace. The On-Call Contract Program allows new employees opportunities to experience and adapt to a new work environment by practicing camp life for short periods of time.

Supervisors have commented that due to the suite of Labour Pool activities, on-call employees are better prepared to cope with the mine employment environment. The On-Call Program allows participants to discuss employment and upward mobility opportunities, gain a variety of employment experiences and decide if the mining work life is for them. The program also allows Agnico Eagle to assess employees to ensure proper placement within the Company.

Employee Turnover = (# of terminations / (Average # of employees for the year))

In 2018, Agnico Eagle Meliadine had a total turnover of 13%. Non-Inuit turnover was 10% and Inuit turnover was 30%.

12.1.3 Summer Student Employment Program

Agnico Eagle offers two summer employment programs that are accessible to students. Firstly, Agnico Eagle's company-wide policy offers a summer employment program to the children of all Agnico employees (both Inuit and non-Inuit) that are undertaking postsecondary education. Secondly, in 2018 Agnico Eagle also offered the Inuit Summer Employment Opportunities postings, which is targeted to Inuit students in high school or post-secondary and tries to match students to positions in their areas of interest. In 2018, Agnico Eagle had one (1) Inuk employee hired through this posting. Agnico Eagle will continue to offer both programs in 2019 and continue to work in collaboration with the KIA to encourage Kivalliq applicants to apply for the programs.

As per Agnico Eagle policies, students must be 18 years or over to work at the Operation, and over 16 years old to work in the offices in Baker Lake or Rankin Inlet.

12.2 TRAINING

Agnico Eagle's Training Management System (TMS) and the Learning Management System (LMS) tracks and reports on training activities. The list of training provided can be found in Appendix L-1.

12.2.1 Pre-employment training

The Labour Pool Process (formerly 'Labour Pool Initiative'), implemented in 2014 and revised in 2015, is based on an agreement between Agnico Eagle and the KIA through the IIBAs to offer pre-employment opportunities to Inuit from all Kivalliq communities.

The goal of the program is to pre-qualify candidates from Kivalliq communities through 5 steps: employment information sessions, online application (facilitated by Employment Information Sessions), the Work Readiness Program, mandatory trainings (more details provided below), and the Labour Pool List (facilitated by the Labour Pool Coordinator).

All applicants that have the minimal requirements to be hired (must be at least 18 years old and have a clean record of employment with Agnico Eagle) are required to complete mandatory training by e-learning as well as participate in the 5-day Work Readiness and Site Readiness training programs. The objective is to create a pool of candidates ready to work that Agnico Eagle and its contractors can draw future employees from.

Figure 12.1 Labour Pool Process

12.2.2 **Work Readiness Training Program**

Agnico Eagle continues to utilize the Work Readiness Training program that was developed as a pre-employment initiative. In 2018, the Work Readiness Training was delivered in collaboration between Aglu Consulting and Training and Northern College. The Work Readiness program is the first step of the Labour Pool Process for those individuals who have applied online who do not have work experience relevant to the positions for which Agnico Eagle hires.

The objective of the program is for Inuit applicants to be better prepared for the work environment in an industrial setting. Graduates of the program are eligible to continue the Labour Pool Process and attend the mandatory trainings given on-site. The program provides coaching on a range of issues including: awareness of employers' unspoken expectations, communication in the workplace, and problem-solving skills for resolving workplace issues.

The program was implemented in April 2013. The program is delivered over a five-day period at the community level and is scheduled throughout the year. In 2018, the program was delivered by a visiting instructor in all seven Kivalliq communities resulting in 183 participants from various communities, from which 85% successfully completed the program.

In 2018, Agnico Eagle partnered with PMC Renewal and the Nunavummi Disabilities Makinnasuaqtiit Society (NDMS); two organizations that delivered Work Readiness program across the Kivalliq through contracts with the GN's Department of Family Services. Agnico Eagle now considers those who have completed this program as an equivalent to the Work Readiness program for those who are interested in gaining employment with Agnico Eagle.

12.2.3 **Mandatory Training (Site Readiness)**

Participants that have successfully completed the Work Readiness Program will be retained for the Mandatory Training Program (called "Site Readiness") and then will become part of the Labour Pool.

The Mandatory Training Program is a five-day training provided at the Meadowbank site. Throughout the week, participants are enrolled in diverse activities such as mandatory training sessions, site visits, job initiation, information sessions on training and career opportunities, as well as interviews and discussions on employment opportunities with a Human Resource representative to assess career ambitions and identify work interest.

Afterwards, candidates wanting to work for the Camp Department are given short term on-call assignments. All other applicants become part of the Labour Pool list until a job opportunity matching their interest and competencies becomes available.

In 2018, 142 candidates successfully completed the Mandatory Training.

12.2.4 **Training Hours**

The following categories of training are available:

- Mandatory: Mandatory training related to compliance with the Nunavut Mine Act, as well as training that is mandated according to AEM Health and Safety policies. Many of these training sessions are offered via e-learning prior to employee's arrival on site.

- General: Training activities required at a departmental level and covers many employees working in different departments. General training includes training on light duty equipment as well as enterprise software systems and cross-cultural training.

- Specific: Focused on developing individual competencies related to a specific position. This training qualifies individual workers for promotion following their progression through the Career Path. These training programs are provided by in classroom (theory) learning as well as practical (one-on-one) learning.

- Emergency Response Training (ERT).

The following table provides the training hours provided to Agnico Eagle employees at Meliadine (excluding contractors) in 2018:

Table 12.3: Training hours provided to Agnico Eagle employees at Meliadine

Type of Training	Inuit	Non-Inuit	Total
Mandatory	482	4,364	4,846
General	248	1,949	2,197
Specific	2,321	4,891	7,212
ERT	100	1,640	1,740
Total	**3,151**	**12,844**	**15,995**

12.3 TRAINING PROGRAMS

12.3.1 E-learning

Before coming to an Agnico Eagle site for the first time, newly hired employees must complete their Mandatory Training online, which consists of six (6) modules: General Induction, WHMIS, Fire Suppression, Job Hazard Analysis and Work Card, Spill Response, and Occupational Health and Safety (Personal Protective Equipment, Ladder Safety, Surface Standard Operating Procedure). The General Induction chapter provides general information about Agnico Eagle and working life at the mines. The e-learning training material has been translated into English, French, and Inuktitut.

As per the requirement of the IIBAs, in 2017 two new e-learning lessons were developed and added to the General Induction. The Inuit Impact and Benefit Awareness module (IIBA) provides general awareness on: Agnico's Commitment to Indigenous People, history of the Nunavut Agreement and the different Inuit organization branches, what an IIBA is and why the sites have one, and a high level overview of the benefits and impact mitigation provided through the IIBAs. The Archaeology module informs workers on how to identify potential archaeological sites (ex. fox traps, tent circles, hunting blinds) and what to do if a worker finds one when working in the tundra. An objective of these lessons is also to

give each employee and contractor employee cross-cultural context before arriving on one of Agnico's sites.

In 2018, three (3) e-learning lessons have been updated: Process Plant Induction, Chemical Awareness and General Induction. The e-learning WHMIS, which is now WHMIS 2015, has been modified according to meet the new WHMIS standards.

12.3.2 **Cross-Cultural**

Implemented first at Meadowbank, the Cross Cultural Training Program is a 5 hour in-class training course. This course allows employees from different cultures and backgrounds to understand each other's culture in order to improve understanding and communication at the workplace.

The program was revisited with the assistance of the Nunavut Literacy Council in 2013, and a revised program was initiated in 2014. This program is mandatory for all Agnico Eagle employees and contractors who will be on site for six months or more. The training is in English, Inuktitut and French, and is offered at Meliadine.

In 2018, Meliadine had 17 sessions.

12.3.3 **Career Paths**

The Career Path Program was designed in 2012 at Meadowbank, with the intention of supporting upward mobility of Inuit employees at Agnico Eagle's Project sites. This program identifies the incremental steps that any employee is required to complete to advance in their chosen career of interest.

The objective is to have only internal promotions of employees, with external candidates being hired only as an entry level position to feed the trainee programs at the base.

In 2018, the Career Path system was developed in five (5) areas of activity at Meliadine: Mine underground (Meliadine only), Field services, Assay lab, Process plant and Maintenance.

12.3.4 **Apprenticeship Program**

The Apprenticeship Program combines on-the-job learning and in-school technical instruction to allow Inuit employees the opportunity to be educated and trained in the trade of their choice. By the end of the program, the apprentice is able to challenge their Certificate of Qualification (COQ) to become a Journeyperson and will also have the opportunity to challenge their Red Seal Exams. Currently, we offer trades (8) for: cook, carpenter, millwright, electrician, heavy duty equipment technician, welder, housing maintainer and plumber.

As of the end of 2018, there were 4 apprentices and pre-apprentices at Meliadine.

12.4 GENERAL SOCIO-ECONOMIC PROVISIONS

12.4.1 Housing and Home Ownership

Agnico Eagle has shared financial literacy materials from its Work Readiness Program as well as details on Agnico's direct rental deduction program with the Nuanvut Housing Corporation in October 2017. Agnico Eagle will reach out again to NHC in 2019 with the intention to collaborate on the topic of home ownership and affordable housing options. Nunavut Housing Corporation is also invited to participate in the Kivalliq Socio-Economic Monitoring Committee.

12.4.2 Labour Force

Agnico Eagle submitted the latest staff schedule on May 2, 2018, and will submit an updated version in 2019. Agnico Eagle also submitted the IIBA-required Labour Market Analysis (LMA) to NIRB in March 2019.

12.4.3 Training and Development

Agnico Eagle works with training organizations and government departments regularly through the Kivalliq Socio-Economic Monitoring Committee, through the IIBA with the Kivalliq Inuit Association, through the Memorandum of Understanding with the Government of Nunavut, and through one-on-one partnerships and collaboration with organizations such as the Hamlet of Arviat, the Nunavut Literacy Council, Nunavut Arctic College, Aglu Consulting, and more.

The listing of formal certificates and licenses was sent to NIRB on November 7, 2018. There have not been any updates since the last submission.

Executive Summary

Agnico Eagle Mines Limited (AEM) retained Golder Associates Ltd. (Golder) to conduct the 2018 annual geotechnical inspection of the Meliadine Gold Project to comply with the requirements of AEM's Water Licence Permit No. 2AM-MEL1631. The inspection was conducted between 10 and 14 of September 2018 and covered the geotechnical aspects for the water management infrastructure, roads, waste facilities, underground portals, infrastructure pads, fuel storage facilities, in the following areas:

- main site
- exploration camp site
- all-weather access road (AWAR)
- Itivia site and by-pass road

This report describes the geotechnical aspects of the areas inspected, presents general observations, recommendations, and provides comments on instrumentation data, where available. In addition, a description of the geophysical and permafrost conditions for the site is provided.

Infrastructure for the mine is progressively being built, including some of the water management collection ponds, associated dikes, the tailings storage facility, open pits, waste rock storage facilities, diversion berms and channels. The inspection was carried out in accordance with the requirements of the Water Licence, for the facilities in existence at the time of the inspection.

The inspection occurred when there was no snow or ice on the lakes or land, following the freshet, and when surface water flows were generally low. Peak surface water flows typically occur during the freshet (May and June). During the inspection the weather was generally clear with some periods of rain. Daily temperatures varied between 0°C and 8°C. Water levels were considered to be normal for this period of the year, and the flow observed at water crossings was low.

AEM's environmental department monitors the water levels and quality in the collection ponds and collects instrumentation data.

The results of the 2018 annual geotechnical inspection carried out at the Project site, along the AWAR, at the Itivia site, and along the Itivia by-pass road indicate that the infrastructure was generally in good condition and performing as designed.

The following presents a summary of the recommendations from the 2018 geotechnical inspection for the infrastructure in each of the areas inspected. The recommendations have been grouped based on the type of recommendation and have also been given a rating of High (L), Medium (M), or Low (L) priority.

The following recommendations are related to surveillance and monitoring:

The recommendations for surveillance and monitoring don't currently require a maintenance action but may warrant future maintenance if conditions worsen.

Main Site

- Geotechnical inspections should be carried out and documented for D-CP1 and D-CP5 following the schedule developed in the OMS manual. In addition, instrumentation should be monitored, and the data should be plotted and reviewed, following the schedule developed in the OMS manual. These activities were completed by AEM in 2018; however, not quite to the schedule in the OMS. The OMS manual indicates that daily inspections should be completed and documented using the same form as the weekly inspection, which were not completed in 2018. The OMS manual does not indicate if there is seasonal variability to the frequency of documented inspections. It may be acceptable to seasonally vary the frequency of inspections, but this should be reviewed with the Engineer of Record (EoR) for the dikes and the OMS manual should be updated, as required. The OMS manual should be reviewed and updated annually and is next due for review in June 2019. (H)
- If the P-Area dikes will continue to be used, they should be added to the OMS manual that was developed for D-CP1 and D-CP5. Geotechnical inspections and instrumentation monitoring should be carried out and documented following the schedule developed in the OMS manual. (H)
- Implement a road and culvert monitoring program for site roads, as is done for the AWAR, which is tied to a maintenance program. (M)
- Conduct inspections along Itivia by-pass road, as per the Road Management Plan (AEM 2015b), now that the road is complete. (M)
- Monitor the cracking adjacent to Channel 5. If cracking gets worse, recontouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks leading to warming of the permafrost and additional thaw settlement and cracking. (M)
- Monitor the cracking observed in the D-CP1 downstream sump berms and adjacent to the downstream collection channel. Recontouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks leading to warming of the permafrost and additional thaw settlement and cracking. (M)
- Ponding upstream of Berm 3 should be monitored to determine how much and how often ponding occurs and if Berm 3 can perform as required with the ponding. (M)
- The Berm 3 cover materials may be susceptible to erosion. This should be monitored, and if there is erosion, consideration should be given to placing coarser material on Berm 3 to reduce the potential for erosion. (M)

Exploration Site

- The cracks in fuel storage pad should be monitored; however, they are not considered to be a geotechnical concern. (L)

All-weather Access Road

- Continue to monitor culverts and hydraulic effectiveness to assess if current culverts provide adequate capacity and if any changes are required. Evaluate if any culverts need to be installed at a lower elevation to reduce ponding, and downstream erosion. (M)
- Monitor areas that have ponding, but no culverts and consider installing culverts to manage water. (M)
- Conduct inspections and document observations and recommendations as laid out in the Road Management Plan (AEM 2015b). Road inspections were completed and documented in 2018, but documentation indicates that the frequency of the inspections did not quite meet what is laid out in the Road Management Plan. (H)

Itivia Site and By-pass Road

- The locations of some of the culverts through the Itivia by-pass road do not correlate with the design drawings (Tetra Tech 2017e) due to changes made during construction. The culvert locations should be referenced to the as-built report and drawings during the 2019 annual geotechnical inspection. (M)
- The as-built report should confirm culvert sizes, locations, and invert elevations have been constructed to the design. The as-built report should also confirm that safety berms have been constructed where required based on road fill height and confirm that road slopes have been constructed to the design. (M)
- The section of the road and safety berm that is constructed with esker material may be susceptible to erosion. This should be monitored and maintenance completed as required. (L)
- Ponding of water along the road should be monitored and if it is impacting the condition of the road, mitigation measures should be implemented, such as, lowering the culverts or ditching or placing fill to direct water to the culvert inlets. (M)

The following recommendations are related to operational procedures:

Main Site

- Water volumes within containment ponds should be managed to the levels defined in the OMS manual, including maintaining the water level below the elevation defined for the end of October in the OMS manual over the winter to promote freezing of the dikes. (H)
- The D-CP1 sump and downstream collection channel should be emptied in the fall/early winter to refreeze the ground around these facilities. During the open water season, keeping the water level in the downstream channel and sump low will reduce the potential for thaw of the ground around the channel and sump and associated settlement. (M)
- Consider adding data loggers to thermistors for easier collection of data, especially in the winter when access may be more limited. (L)
- Where possible, try not to allow seepage water from DP3-A to pond against the Saline Pond berm to avoid permafrost degradation. (M)

- Monitor slopes above Portal No. 2 for rockfill instability during backfill placement. (H)
- Snow management around Portal No. 1 and 2 may be advisable prior to freshet to reduce inflows to the underground. (L)

Exploration Site

- Minimize the amount of water contained within the exploration landfarm until it is decommissioned and remediated. (M)

The following recommendations relate to maintenance or repairs that are required:

Main Site

- Cracks and areas of settlement in the containment pond dikes should be filled and/or recontoured to close the cracks and reduce the potential for infiltration and erosion. (M)
- Ponding of water adjacent to roads should be avoided. Disturbed areas from road construction should be recontoured to promote drainage away from the road and consideration should be given to installing culverts if ponding occurs in naturally low areas. This was most notable along the Emulsion Plant and Wesmeg Borrow access roads. (M)
- If the Wesmeg Borrow access road is blocking drainage near Lake B33A that is leading to ponding adjacent to the road, a culvert should be installed to allow drainage so that there isn't permafrost degradation and settlement. (M)
- Consider adding a crushed surface material to the Emulsion Plant and storage area pads if trafficability continues to be an issue. (M)
- Survey monitoring plate M-3 on D-CP5 should be replaced. (M)
- Where erosion is occurring on slopes of pads, the existing materials should be regraded and compacted, and a coarser material should be placed to further reduce erosion potential. Higher priority should be given to areas where erosion is encroaching on sea containers or other facilities placed close to the slope. The most significant pad erosion was observed at the north side of the main camp/industrial pad and the Emulsion Plant pad. (M)
- The cracking and sloughing along Channel 1 should be assessed to determine if the channel is too steep and riprap is sloughing over geotextile or if it is caused by thermal degradation of permafrost adjacent to the channel. If possible, the channel should be kept empty through the winter to promote freezing of the permafrost around the channel. (M)
- Where access is feasible, removal of snow from the water collection pond dikes (temporary and permanent) is recommended to reduce the insulating effects of the snow, thereby allowing the temperature of the core material in the dikes and the foundations to drop as low as possible. Snow removal is more important if thermistor data is indicating that the dike and/or foundation temperatures are warmer than expected. (M)

- Make sure thermistors in the water management dikes are well marked so they can be located and maintained during the winter and are not damaged during snow removal operations. (H)
- The slopes of the Operation Landfill should be monitored, particularly the northeast corner where water was observed to be ponding downstream and there was some possible sloughing on the slope. Regrading and compacting the slope in this area will reduce the potential for erosion. (M)
- Consider adding rockfill material to cover the till berm in P1, to protect the till and maintain its integrity if this berm is required for water management. (L)
- The Wesmeg Borrow Area should be recontoured and either capped with a coarser material or revegetated to reduce erosion. (M)
- A coarser rockfill layer should be placed over the decommissioned exploration landfill to reduce erosion and cracking. (M)
- Snow management around and above Portal No. 1 and 2 may be advisable, especially prior to freshet, to reduce the potential for larger surface water inflows entering the underground. (L)

Exploration Camp Site

- Repair surface erosion along south slope of exploration camp pad. Grade surface to reduce channelization of surface water flows and therefore reduce the potential for the erosion to reoccur. In this area, a coarser surfacing layer could be placed to help reduce the potential for future erosion. (L)
- The exploration camp access road should be regraded and consideration given to placing some coarser rockfill on the slopes where there is erosion. (M)
- The culverts through the exploration camp access road should be cleared of material. Large boulders should be removed from above culverts to prevent potential damage to the culverts and appropriately sized riprap should be added to the road fills around he culverts for erosion protection where there isn't any. (M)
- The diffuser access road could be regraded to close up the cracks and reduce the potential for future cracking. (L)

All-weather Access Road

- The kilometre markings on the AWAR culverts should be checked and replaced with accurate numbers. At the time of the 2018 site visit, AEM indicated that new markers had been ordered, but had not arrived. (M)
- Specific recommendations for the AWAR culverts and bridges are summarized in Table 9.

Itivia Site and By-pass Road

- Cover material should be re-established over the liner that has been exposed on the south containment berm of the Itivia fuel storage facility to protect the liner. (M)
- The culverts should be cleared of all materials prior to freshet. (H)

The following recommendations relate to future construction:

- Road and pad materials should be compacted to reduce the potential of the material being eroded, and if necessary a coarser, well graded, cover material should be placed to further reduce erosion potential.
- When culverts are installed, ensure bedding material surrounding culverts is of a suitable gradation (e.g., sandy) and compacted. Large boulders should not be placed in direct contact with the culverts within the road fills; however, the slopes of the road around the outlets of the culverts should be armoured with appropriately sized material (e.g., cobbles) to reduce erosion.

Study Limitations

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

1.0 INTRODUCTION

Agnico Eagle Mines Limited (AEM) is developing the Meliadine Gold Project (the Project). It is located approximately 25 km north of Rankin Inlet, in the Kivalliq Region of Nunavut. A series of open pits as well as underground development will be used to extract gold.

AEM retained Golder Associates Ltd. (Golder) to conduct the 2018 annual geotechnical inspection for the Project, pursuant to the requirements of the Type A Water Licence Permit No.2AM-MEL1631 (Nunavut Water Board 2016).

Under Part I, Item 14 (page 21) and Schedule I, Item 1 (page 39) of the Water Licence, AEM is required to undertake an annual geotechnical inspection of its facilities between the months of July and September. The inspection is to be carried out by a geotechnical engineer, and to be in accordance with the Canadian Dam Association (CDA) *Dam Safety Guidelines* (CDA 2013), where applicable. The inspection occurred between 10 and 14 September 2018, and was conducted by Allison Isidoro, a geotechnical engineer, holding professional registration in Nunavut, and employed by Golder.

Construction of the infrastructure for the Project has commenced and will continue in stages as development and mining progresses. The following structures were inspected:

- main site including
  - P-Area temporary collection ponds (P1, P2, and P3) and associated dikes (DP1-A, DP1-B, DP2-A, DP3-A)
  - permanent water collection ponds CP1 and CP5 and their associated dikes (D-CP1 and D-CP5) and jetties
  - diversion Berm 3
  - diversion channels 2, 3, and 5, and partially completed diversion channel 1 (including Culvert 16)
  - saline pond
  - site roads
    - main site pad area roads, including culverts 2, 3, and 4
    - Tiriganiaq Esker access road
    - Wesmeg access road, Wesmeg Borrow and vent raise
    - magazine storage access road
    - main site water intake access road
    - emulsion plant pad access road, including Culvert 13
    - CP4 access road
    - landfill access road, future TSF area, including Culvert 1

- pads
  - main camp pad
  - industrial pad
  - east ventilation raise pad
  - temporary cyanide storage pad
  - effluent water treatment plant pad
  - explosives (ANFO plant) pad and magazine storage
  - emulsion plant pad
- ore and waste rock storage areas
- landfarm
- exploration and operations landfills
- underground Portals No. 1 and No. 2
- industrial fuel storage and mine site fuel storage

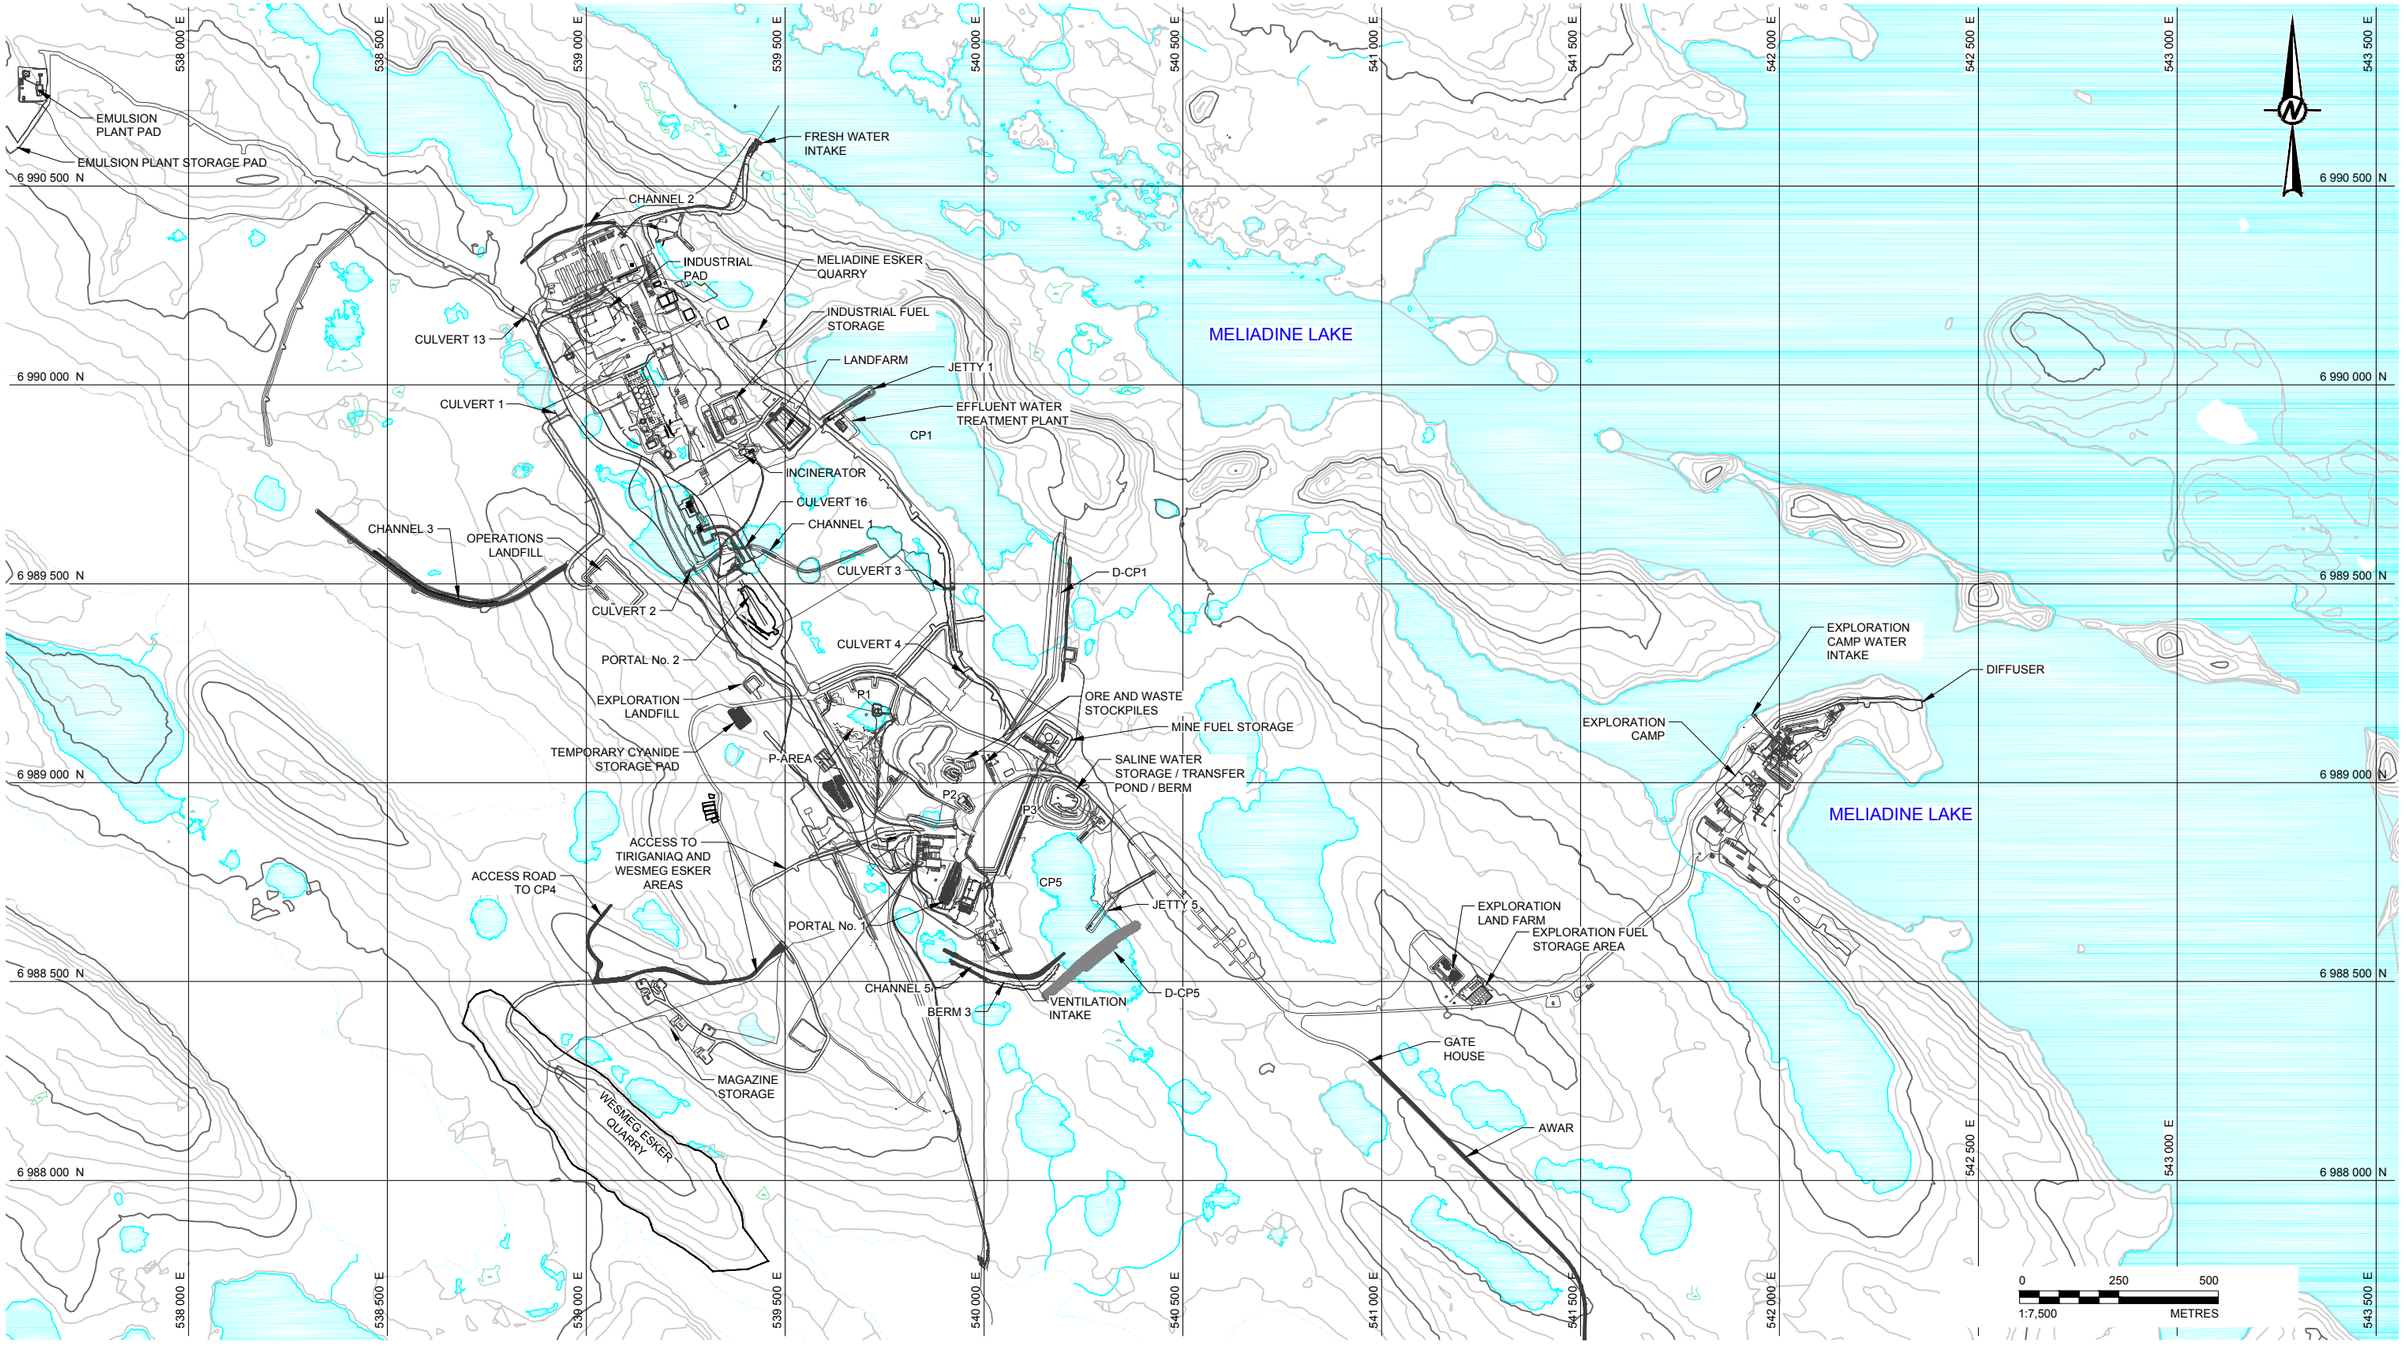
- exploration camp site including
  - site pad and diffuser access road
  - genset storage area
  - fresh water intake
  - access road
  - landfarm
  - fuel storage
- all-weather access road (AWAR)
- Itivia site
  - fuel storage
  - bypass road

The facilities at the main mine site and exploration camp areas that had been constructed at the time of the 2018 inspection are shown in Figure 1. At the time of the inspection, the P-Area had been completed in addition to permanent water management pond dikes D-CP1 and D-CP5. Diversion Channels 2, 3, and 5 were complete and Channel 1 was partially complete. Berm 3 was constructed. Berm 2 was under construction and was not inspected. Some site service roads were in place with the associated culverts and ditches constructed to manage water around infrastructure and roads. Construction of the industrial pad and infrastructure was ongoing. Underground Portal No. 1 was operational. Underground development was occurring, with associated waste rock and ore being hauled to the surface and placed in stockpiles. The culvert over the entrance to underground Portal No. 2 was being backfilled and the drift was being advanced. The operations landfill and landfarm facilities had been constructed. The effluent water treatment plant and associated intake had been constructed. The fresh water intake pump and associated pipeline were in place and an access road had been constructed to within a few metres of the lake. The pipeline was running along the toe of the road. The mine site and industrial site fuel storage facilities had been constructed. The saline water pond had been constructed and was storing water. The emulsion plant and access road had been constructed.

The exploration camp site was the first area of the Project to be developed. The exploration site was inspected, including the site pad, fresh water intake, diffuser access, landfarm, fuel storage, and access road.

Many other aspects of the future development for the Project had not been constructed at the time of the visit including: the water management collection ponds (CP3, CP4, and CP6) and associated dike (D-CP6) and thermal Berms for CP3 and CP4, tailings storage facility, open pits, waste rock storage facilities, ore storage facilities, Diversion Berm 1, several diversion channels (4, 6, 7, and 8). Diversion Berm 2 was partially completed and Ore Storage Pad 2 (OP2) was under construction at the time of the inspection. The final layout of the main site, including water management structures, is shown on Figure 2. A modification was made to the plan for CP3 and CP4 in 2018 to excavate to create storage for these ponds along with construction of thermal berms on the downstream sides of the ponds. This modification was made after the 2018 Water Management Plan (AEM 2018) was issued so Figure 2 still shows dikes D-CP3 and D-CP4 which are no longer planned. This modification will be incorporated into the 2019 Water Management Plan.

The AWAR connecting Rankin Inlet to the Project provides one-way traffic access (with pull-outs to allow vehicles to pass) and was in use.



The Itivia shipping and fuel storage site in Rankin Inlet was complete. The Itivia bypass road was completed the week of the inspection.

Where applicable, the inspection was performed consistent with the principles set out by the CDA (2013). The inspection consisted of visually observing each of the facilities listed above; taking photographs to document the conditions at the time of the inspection (Appendix A, Appendix B, and Appendix D); reviewing instrumentation data (Appendix C), inspection reports, and other relevant files and reports (listed in the reference section of this report); communication with AEM on-site staff (Ms. Jennifer Pyliuk, Mr. Jeffrey Pratt, and Mr. Daniel Gorton); and preparation of this report to document the inspection.

The inspection occurred when there was no snow or ice on the lakes or land, following the freshet, and when surface water flows were generally low. Peak surface water flows typically occur during the freshet (May and June). During the inspection, the weather was generally clear with some periods of rain. Daily temperatures varied between 0°C and 8°C. Water levels were considered to be normal for this period of the year, and the flow observed at water crossings was low.

The site water management plan (AEM 2018) provides a summary of the water management infrastructure and the overall water management approach.

This report describes the geotechnical aspects of the areas inspected and presents general observations and recommendations. In addition, a description of the geophysical and permafrost conditions for the site is provided.

1.1 Scope Limitations

The scope of the inspection is limited to observation of the geotechnical aspects of each of the facilities listed above and review of the associated instrumentation data. The inspection did not include other assessments such as structural, mechanical, or environmental.

For additional information related to the limitations of this scope, reference should be made to the Study Limitations at the beginning of this report.

2.0 GEOPHYSICAL AND PERMAFROST CONDITIONS

The Project is located in the Kivalliq Region, near the northern border of the southern Arctic terrestrial eco-zone, and within the Arctic tundra climate region. It is located within the Churchill geological province, which forms part of the northern Canadian Shield.

The landscape is dominated by features characteristic of glaciated terrain and exposed bedrock. Primarily underlain by Precambrian granitic bedrock, the terrain consists of broadly rolling uplands and lowlands. The Project is located at an approximate elevation of 60 metres above sea level (masl) with a maximum topographic relief of 20 m. There are numerous small lakes, wetlands, and creeks, indicating poorly drained conditions. The upland areas are generally well drained. A series of low relief ridges composed of glacial deposits oriented northwest–southeast control the regional surface drainage pattern. Periodic ice blockages at outlets of small lakes and wetlands occur during the freshet, these can temporarily increase the downstream flood peak discharges and affect the flood characteristics. High flows are observed during the freshet, while low flows and dry stream channels are typical in late summer.

Soils are typically Cryosols. Glacial moraine deposits are predominant, ranging in thickness from veneers (less than 2 m) to blankets (2 to 5 m) to hummocky deposits (5 to 15 m). Glaciofluvial deposits are also present, with the most prominent being a network of sinuous eskers. Lacustrine deposits occur in association with the numerous lakes. Near the coast of Hudson Bay, finer textured marine sediments cover the ground surface.

The Project is located in a zone of continuous permafrost and has an annual average air temperature of -10.4°C, based on climate data from Rankin Inlet. Within the permafrost there are intervening taliks (areas of unfrozen ground) and thaw bulbs induced by lakes. The permafrost in the region is considered to be “cold” (i.e., has an average annual surface temperature and zero amplitude temperature of less than -4°C). The depth of permafrost and of the active layer varies based on the proximity to lakes, soil thickness, vegetation, climate conditions, and slope direction. Based on thermal studies and measurements of ground temperatures, the depth of permafrost is generally between 360 to 495 metres below ground surface (mbgs). The depth of the active layer ranges from about 1 mbgs in areas with shallow surficial soils, up to about 3 mbgs adjacent to the lakes (AEM 2014b). The typical permafrost ground temperatures at the depths of zero annual amplitude are in the range of -5.0°C to -7.5°C in the areas away from lakes and streams, and generally are reached at a depth of 15 to 35 mbgs. The geothermal gradient ranges from 0.012°C/m to 0.02°C/m (Golder 2014). The ground ice content in the region is expected to be between 0% and 10% (dry permafrost) based on the regional scale compilation data and the Canada Permafrost Map published by Natural Resources Canada (NRC 1993). However, areas of local higher ground ice content occur and are generally associated with low lying areas of poor drainage.

Taliks may occur where lake depths are greater than about 1 to 2.3 m. The presence and extent of each talik is influenced by the geometry (size and shape) of the lake. As the depth and size of lakes increase, the extent of the talik increases. Formation of an open-talik, which penetrates through the permafrost, would be expected for lakes that exceed a critical depth and size. It is anticipated that open-taliks exists below Meliadine Lake, Lake B7, and Lake D7 based on their depth and geometry (Golder 2013).

The salinity of groundwater also influences the temperature at which the groundwater freezes. Testing has indicated that the salinity of the groundwater in the Project area generally increases with depth. Test results on two deep groundwater samples collected below the base of the permafrost as part of the baseline study indicated salinity level leads to a freezing point depression of about 3.2°C (AEM 2014a, Volume 7, Appendix 7.2-A).

Thermistor cables have been installed to monitor natural ground temperatures in the vicinity of the Project. Data are presented in Appendix C along with plan views of thermistor installation locations (Figure C1 and C2). Several of these thermistors have stopped working over the last several years, mainly due to damage as construction of mine facilities expands into the areas where these thermistors have been installed. Readings taken in 2018 in the remaining operational thermistors are generally consistent with previous trends. There were some erroneous readings that have been removed from the plots for GT09-07, GT09-08, GT11-02, GT14-03, and GT14-27. These thermistors showed large jumps in temperature for one set of readings, which then returned to be in line with previous temperatures when they were read the next month. Most of the erroneous readings were on 6 September 2018. Thermistor GT14-03 also had erroneous readings on 19 June 2018 and GT14-27 had erroneous readings on 25 May 2018 and was then reported to be damaged.

Priorities and frequencies for reading these thermistors are summarized in AEM (2015c) and are based on the development sequence for the mine. Thermistors located in close proximity to the process plant and other mine infrastructure have the highest priority and are read more often. Thermistors located in the Tiriganiaq open pit area are given the next priority. The thermistors installed to monitor the deep permafrost are given the lowest priority as the conditions within the deep permafrost do not fluctuate seasonally, so fewer readings are required.

3.0 P-AREA TEMPORARY DIKES AND COLLECTION PONDS

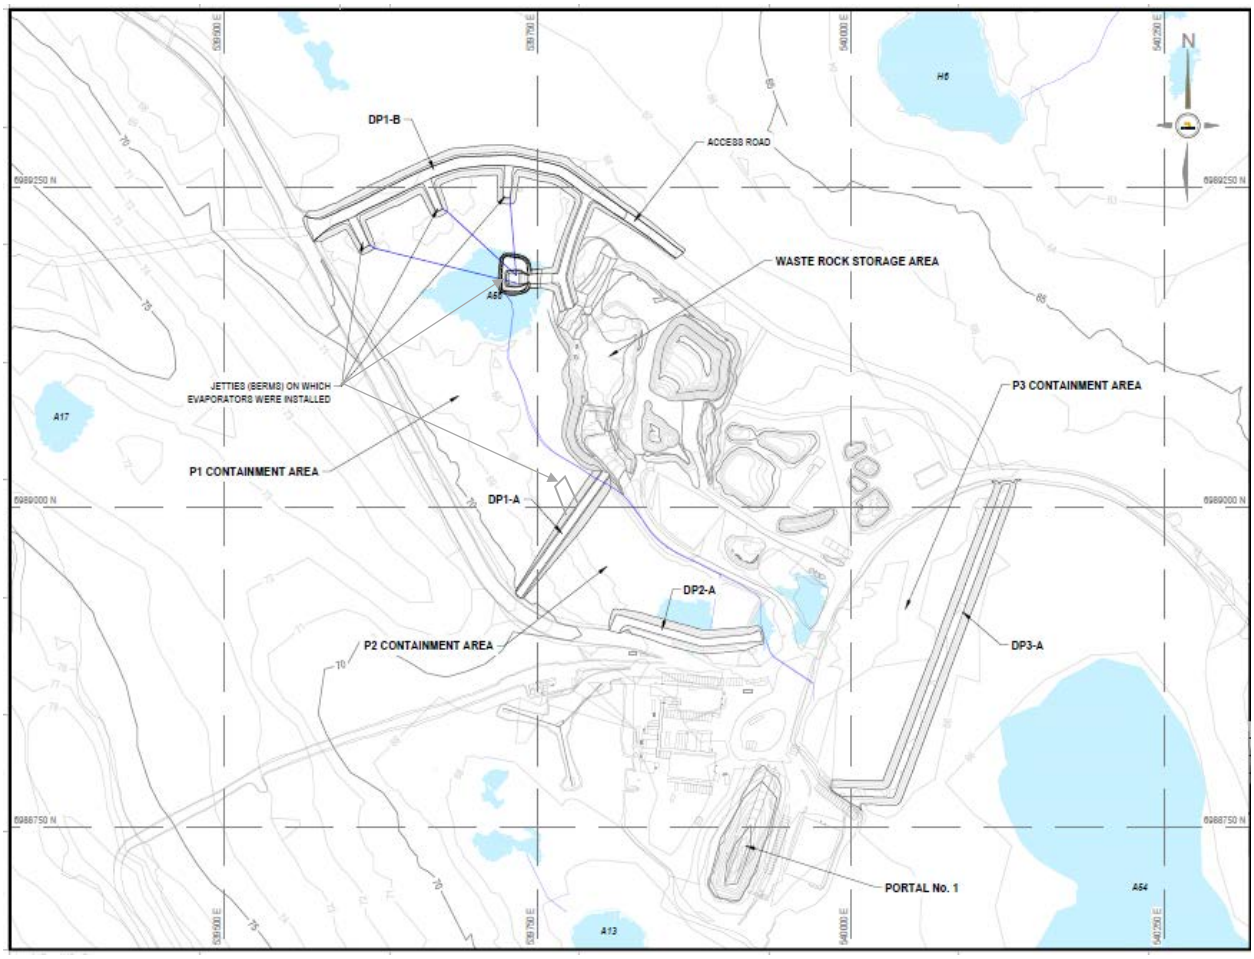
During the winter of 2016, it was recognized by AEM personnel, as an interim measure to manage an emergency situation, that temporary water collection ponds were required to collect and manage surface runoff water near underground Portal No. 1 and the waste rock storage area (AEM 2016a). The concern related to the potential that surface runoff water from the ore and waste rock stockpiles could contain elevated chloride and ammonia concentrations, above the permitted discharge criteria standards per the Metal Mining Effluent Regulations under the Fisheries Act and/or Canadian Council of Ministers of the Environment guidelines for the protection of aquatic life.

Therefore, prior to the 2016 freshet, four temporary containment dikes (referred to as DP1-A, DP1-B, DP2-A, and DP3-A) were constructed between 25 March and 10 May 2016 to create three temporary ponds (P1, P2, and P3) to manage the runoff near Portal No.1 and from the waste rock storage area (Figure 3). Representatives from Tetra Tech EBA were on site during the majority of dike construction to provide geotechnical assistance, monitor the construction, and prepare the construction record report (Tetra Tech EBA 2016c).

The collection ponds are referred to collectively as the P-Area. The dikes do not completely enclose the ponds. Portions of the pond boundaries are associated with natural areas of higher ground, the ore and waste stockpile area, and/or existing roads. These roads were not built as water containment structures. Similarly, the stockpiles of ore and waste are granular in nature and do not function as water containment structures on a year-round basis.

In general, the P-Area receives direct precipitation, runoff from the site roads immediately surrounding the area and runoff and pore water from the ore and waste rock stockpiles near Portal No. 1. Water from underground is also pumped to the P-Area, typically via the Saline Pond. Pipelines and associated pumping systems exist to allow water to be transferred from P2 and P3 to P1. Five evaporator units have been installed within P1, including two new evaporators installed since the 2017 inspection. The new evaporators were installed on the east berm of the snow melt pond and on a jetty constructed off the north slope of DP1-A. A pumping station within P1 connects to the evaporators.

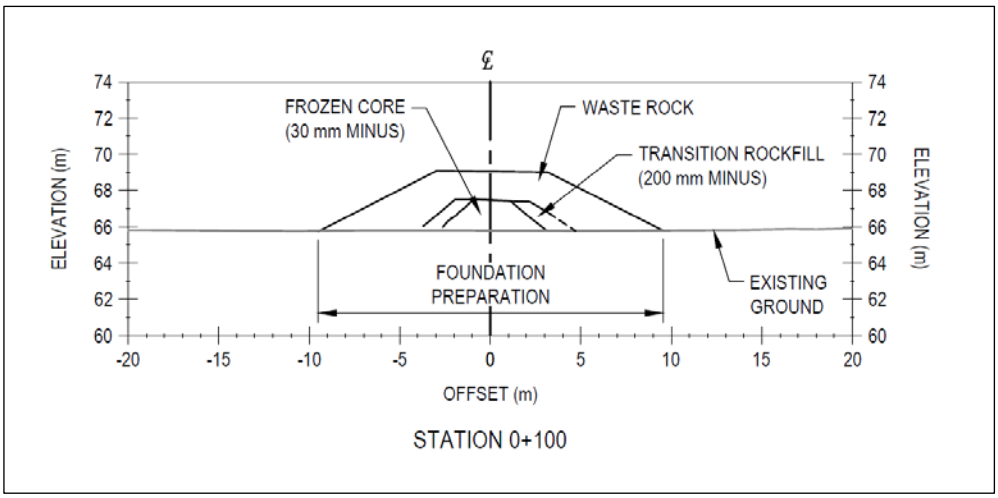
In accordance with the CDA (2013), dam classification is assigned based on an assessment of the consequence of failure, evaluated on the basis of potential incremental losses of life, environmental and cultural values, and third party infrastructure and economics. The class is determined by the highest potential consequence ranking. Although these dikes are less than 2.5 m in height (to the top of the water retaining element, the frozen core), and therefore do not meet the definition of a dam (CDA 2013), A consequence classification of significant was initially assigned to these structures in 2016 for the purpose of operation and monitoring. This classification was based on the following: failure of the dikes would not be anticipated to cause any loss of life, loss to cultural values, nor loss to third party infrastructure and economics. The environmental consequence, if any, to downstream fish-bearing lakes, which is Lake A8 for this particular situation, would be expected to be short term, with restoration or compensation in kind highly possible. Since dikes: DCP-1 and DCP-5, and Berm 3 have been constructed, any potential breach or seepage from the P-Area dikes would be expected to report to either CP1 or CP5, and therefore, the associated potential short-term environmental risk to Lake A8 has been eliminated. Based on the containment of a potential failure these structures are no longer considered as dams in accordance with the CDA classification (CDA 2013). However, as these structures serve a purpose for the mine operation, AEM have been regularly managing water within the ponds, and visually monitoring the containment structures associated with the P-Area.



The central zone of each of the four P-Area containment dikes was intended to be constructed of saturated crushed (30 mm minus) material that was to freeze and become a frozen core, thereby forming the water-retaining element of each dike. Due to construction delays, temperatures became too warm to freeze the core part way through the construction, so the central cores were not frozen to the planned elevations and in some cases not frozen at all during construction. The thermal conditions of the cores of the dikes during operation is further discussed in Section 3.2. The following is a summary of the frozen cores that were completed during construction:

- DP1-A minimum saturated and frozen core elevation was 67.9 masl at the time of construction
- DP1-B entire core unsaturated
- DP2-A entire core unsaturated
- DP3-A saturated core elevation varied along the length of the dike, with a minimum elevation of 65.7 masl at the time of construction

Transition material (200 mm minus) was placed on the upstream and downstream sides of the core, with additional coarser grained rockfill placed further upstream and downstream and above the core. The upstream and downstream slopes are approximately 2 horizontal to 1 vertical. The maximum height of the core of any of the dikes is approximately 2.5 m, and the maximum height of the entire dike (core and thermal cover) is 4 m. Figure 4 shows a typical section through one of the dikes (DP3-A).



Temporary single bead thermistor cables were installed at selected locations at the crest of the frozen core to monitor the initial thermal conditions at these locations. These instruments functioned for a few months after installation. Six new vertical thermistors were installed in 2017. Their locations are shown in Figure C3 (Appendix C). Additional information regarding the thermal conditions and monitoring of the dikes is provided in Section 3.2 and thermistor data is provided in Appendix C.

Appendix A1 contains a summary of photographs of the temporary dikes and collection ponds from the 2018 inspection.

Source: Tetra Tech EBA 2016c.

Figure 3: P-Area and Dikes DP1-A, DP1-B, DP2-A, DP3-A

Source: Tetra Tech EBA 2016c.

Figure 4: Typical Section through Temporary P-Area Dike DP3-A

There are no spillways in the dikes. Water levels within each pond are controlled through pumping and the use of the evaporators installed within P1. P1 was subdivided into two areas by an internal berm constructed after the completion of P1. Details regarding the internal divider berm are not included within the P-Area construction record report, nor is its location shown on the drawings. As the divider berm is internal, the lack of information is not a concern.

A lined pond was constructed in the northwest corner of P1 in May 2017 to contain contaminated snow from a fuel spill at the exploration camp fuel farm. The snow melt water was treated with an oil water separator in September 2017 and the clean water was pumped to CP1. The snow and rain that collects in the snow melt pond has continued to be treated. The snow melt pond will be decommissioned.

The P-Area area temporary dikes and collection ponds are intended to be an interim measure during development of the site to manage the runoff water until permanent water management dikes and collection ponds are constructed and operating to the design and the saline water treatment plant is operational. As the project advances, the P-Area will become covered by waste rock and soil as Waste Rock Storage Facility 2 is developed.

Table 1 provides a summary of key information regarding the construction of each dike and thermistor installation locations.

Table 1: Summary of Key Dike Information and Thermistor Locations

Dike Structure	Minimum Elevation of Core	Minimum Saturated Elevation of Core [(a)]	Minimum Dike Rockfill Crest Elevation	Maximum Pond Operating Elevation [(b)]	Thermistor Location
DP1-A	68.9 m	67.9 m	70.3 m	68.5 m	no instrumentation
DP1-B	68.9 m	none	70.5 m	68.5 m	DCP1B-1: Stn 0+150 DCP1B-2: Stn 0+220
DP2-A	67.9 m	none	69.5 m	67.25 m	DCP2A-1: Stn 0+090
DP3-A	67.4 m	65.7 m	69.0 m	66.35 m	DCP3A-1: Stn 0+050 DCP3A-2: Stn 0+150 DCP3A-3: Stn 0+250

(a) At the time of construction.

(b) Water level associated with a 24-hour duration extreme rainfall event with a return period of 1:100 years, which would bring the elevation to within 300 mm of the top of the core. (File: 20160530 P1_P2_P3 Water Balance for 2016.xlsm, P1-Area Water Balance, Tetra Tech 2016c).

Stn = Station (distance) along centreline of each dike from the starting reference point.

3.1 Visual Observations

The inspection involved walking along the crest of the dikes (DP1-A, DP1-B, DP2-A, and DP3-A), examining the condition of the upstream and downstream slopes of the dikes for visual signs of deformation and instability, cracking, and uneven surfaces. Due to ponded water and saturated conditions it was not possible to walk along the downstream toes of DP1-B and DP3-A. Each pond contained water at the time of the site visit, so it was not possible to walk the upstream toe of the dikes. Seepage occurrences and/or indications of seepage were noted along the downstream toes. A photographic record of the inspection, with annotations added, where appropriate, is included in Appendix A1 (Photograph 1 through 37).

At the time of the inspection, the following general observations were made:

- Overall, the dikes appear stable, with no significant geotechnical concerns identified.
- The dikes do not completely enclose the ponds. The ore and waste stockpile area and existing roads form a portion of the pond boundaries. Neither the stockpiles nor the roads function as water containment structures, on a year-round basis. Collectively, the ponds and the associated dikes appear to capture the majority of the surface water runoff from the area of concern.
- The P1 divider berm appears to have been constructed of till with some rockfill on the downstream slope, as shown in Photograph 22 (Appendix A1).
- Water was ponded in the seepage collection channels and sumps constructed downstream of DP1-B and DP3-A and water was being actively pumped back into the ponds from the downstream collection systems at the time of the site visit. Water in the collection channels was clear. Seepage from DP1-B was slightly less than in 2017 and the water level in the seepage collection channel was also slightly lower. The ground between the downstream dike toes and the seepage collection channels was saturated at DP1-B and DP3-A and water was ponded along the toe, over the tundra at DP3-A which was more substantial than in 2017 (e.g., Photographs 13 through 16 and Photographs 30, 35, and 36, Appendix A1). Due to the ponded water and saturated tundra, it was not possible to walk directly along the toes of DP1-B and DP3-A.
- As noted in previous annual inspection reports (Golder 2017 and 2018), the rockfill used as thermal cover above the core and on the upstream and downstream slopes of the dikes was of variable grain size, particularly for DP2-A and DP3-A (e.g., Photograph 24 and Photograph 36 Appendix A1). Finer rockfill was observed on the crest of DP3-A (e.g., Photographs 32 and 34, Appendix A1). The crest of DCP1-B was also observed to have a cap of finer material which may have been placed or may be due to traffic on the dike crest.
- There was some minor erosion and/or sloughing on the slopes (e.g., Photograph 10), particularly where cables are laid along the slope and where water has been pumped into the pond. Cracks and periodic small depressions were observed in selected areas of DP1-A (e.g., Photographs 3 and 4, Appendix A1), DP1-B evaporator jetty 2 (e.g., Photograph 12, Appendix A1), DP2-A (e.g., Photograph 26 and 27, Appendix A1), and DP3-A (e.g., Photographs 31 and 33, Appendix A1). The cracks observed in the DP1-B jetty 2 and the east end of DP2-A were the most substantial and had increased in size since the 2017 inspection; these areas should be the priority for remediation and ongoing monitoring.

- Circular cracks with settlement (vertical displacement or slump) and small circular voids were observed during the 2016 inspection along the upstream slope of DP2-A, near Stn 0+40. The observed settlement and cracking may have been associated with 1) thawing of the foundation soils, in particular, if the soils were ice-rich, and/or 2) melting of snow or ice that may have been entrapped within the transition and rockfill material at the time of construction. At the time of the 2017 inspection, fine rockfill was observed to have been used to remediate the slope in the area of the settlement. There were no additional signs of instability in the immediate vicinity of this area; however, there was some minor slumping observed along the upstream crest near Stn. 0+60 (Photograph 26).
- Water levels within each pond are measured daily during the open water season, and the pond levels were generally maintained below the maximum design water elevation except for P3, which was above the design maximum pond elevation for most of June and July 2018 and P2 which rose above the maximum elevation for a few days at the end of July and beginning of September 2018.

3.2 Geotechnical Instrumentation and Monitoring Data

Single bead thermistors were installed by Tetra Tech EBA at the crest of the core (30 mm minus) material, at selected stations along each dike during construction. These thermistors stopped working in August 2016 (a few months after installation).

Six vertical thermistors were installed in the P-Area dikes on 30 September and 2 November 2017. Two were installed in DP1-B, one was installed in DP2-A, and three were installed in DP3-A (Figure C3, Appendix C2). The thermistors were read by AEM staff after installation and throughout 2018. After the completion of installation, the instruments were read between 23 and 25 times through to 4 November 2018. The instruments were typically read 2 times per week during freshet, weekly through the rest of the open water season and then approximately monthly through the winter. Updated plots of the thermistor data are provided in Appendix C2.

Initially after installation of the instruments, the data indicated that the dikes, and the foundation materials directly below the dikes, were at or below 0°C by late October to early November 2017. All instrument nodes remained at or below 0˚C throughout the winter until early June 2018 when temperatures rose above 0˚C. Although the cores of the P-Area dikes were not constructed to the saturated frozen condition intended, it appears that following the initial construction and first summer of operation, the temperatures within the cores of the dikes have been below zero for most of the year, as indicated by the thermistor data (Appendix C). It is likely that portions of the core have become saturated due to seepage through the dikes that freezes in the winter. The performance of the dikes, as frozen core structures, is more important during the freshet, when water levels tend to rise within the ponds. In the fall, when temperatures within the core tend to be the warmest or thawed, water levels within the facilities tend to be lower, and therefore less seepage through them is anticipated.

The complete set of data received by Golder represents a range for one seasonal cycle (14 months from September 2017 to November 2018). As discussed in Section 2.0, the salinity of the groundwater at the Project site can result in freezing point depression of up to 3.2˚C at depth. The salinity of the groundwater increases with depth so the freezing point depression near surface is expected to be less, but frozen conditions may not occur at 0˚C. The review of the data provided in the following bullets represent the thermal conditions for 2018:

- DP1B thermistor (DP1B-1 and DP1B-2) data shows a maximum depth of temperatures above 0˚C of 2.8 m (elevation 68.0 m) recorded on 30 September 2018. The nodes within the dike foundation remained below -1˚C during 2018.

- DP2A thermistor (DP2A-1) data shows a maximum depth of temperatures above 0˚C of 3.6 m (66.04 m) recorded on 30 September 2018. The nodes within the dike foundation remained below -1˚C in 2018.
- DP3A thermistor data (DP3A-1, DP3A-2, and DP3A-3) shows the maximum depth of temperatures above 0˚C varies between the three instruments. The data indicates that the greatest depth of 0˚C was measured at the central thermistor (DP3A-2 at station 0+150); this thermistor recorded temperatures greater than 0˚C to its full depth (4.5 m) for four readings during the month of September 2018. Thermistors DP3A-1 (station 0+050) and DP3A-3 (station 0+250) identify a maximum depth of 0˚C measured at 4.4 m (elevation 64.67 m), and 2.7 m (elevation 66.37 m), respectively. The data from DP3-3 on 17 September 2018 is considered erroneous based on the readings collected before and after. The nodes within the dike foundation remained below 0˚C at DP3A-3, but temperatures rose above 0˚C to a depth of approximately 1.4 m into the foundation below DP3A-1. Data from thermistor DP3A-2 shows that temperatures above 0˚C extend into the foundation from 19 July to 4 November 2018.
- In general, all thermistors showed all beads at or below 0˚C by 4 November 2018. The exception is thermistor DP1B-1 in which the last recording provided was for 30 September 2018; node 4 of this thermistor located within the dike fills remained at 1.0˚C. This may be an erroneous reading as the nodes within the dike above and below node 4 showed consistent temperatures near 0˚C.

Table 2 provides a summary of the key thermal observations at the P-Area thermistors in 2018.

Table 2: Summary of P-Are Dike Instrumentation

Dike Structure	Instrument Name	Instrument Location	Maximum Depth of 0 C Temperature (m)	Minimum Elevation of 0˚C Temperature (m)
DP1-B	DP1B-1 DP1B-2	Station 0+150 Station 0+220	2.8 2.8	68.05 68.05
DP2-A	DP2A-1	Station 0+090	3.6	66.04
DP3-A	DP3A-1 DP3A-2 DP3A-3	Station 0+050 Station 0+150 Station 0+250	4.4 > 4.5 2.7	64.67 64.67 66.37

In 2018, AEM staff performed the following monitoring activities:

- Recorded the daily volumes of water pumped from underground to the P-Area.
- Recorded the daily volumes of water transferred between the ponds.
- Measured and recorded water elevations within each pond during the open water season on a graph with the maximum allowable pond elevation.
- Performed daily inspections of pond and seepage water condition (e.g., frozen or thawed, clear or cloudy) at water management facilities during the freshet (11 May to 14 June 2018).

- Collected samples from the P-Area approximately every one to two weeks for water quality analysis from 10 June to 8 September 2018
- Geotechnical inspections were completed and documented twice for each of the P-Area dikes, one in July and one in September. The inspections included observations of cracking, sloughing, and seepage, and included photographs. AEM prepared visual tracking sheets for each dike by adding sketches of the locations of their observations to plan drawings of the dikes. The observations made by AEM were consistent with the observations from the 2018 annual inspection.

The information collected is contained within various spreadsheets and reports, which were provided to Golder for review.

An operation, maintenance, and surveillance (OMS) manual, including an emergency response plan and emergency preparedness plan, has been prepared for D-CP1 and D-CP5 (AEM 2018) but it does not include the P-Area dike structures.

3.3 Recommendations

The following recommendations are provided regarding the temporary dikes and ponds, for the period of their operation:

- Cracks with settlement (vertical displacement or slump) and small circular voids evident along the dikes should continue to be monitored. If the dikes continue to be used, consideration for filling in the cracks, with additional fine rockfill or granular fill, regrading, and re-compacting the slopes and crests may be warranted. This work could reduce the potential for infiltration into the dikes that could lead to thermal degradation of the frozen core and foundation and could also lead to further instability of the jetty and dike thermal cover materials that could result in material sloughing into the pond. The slumping and cracking along DP2-A and the jetty for Evaporator #2 was more substantial than observed in 2017; there was more settlement observed at the crest of DP2-A and the cracks in the dike and jetty were wider and deeper than in 2017. These areas should be monitored closely as there is the potential for the jetty or dike to slump into the P1 or P2, respectively. A failure of the evaporator jetty or upstream slope of DP2-A are not a risk to a release of water from the ponds but a failure could affect operations and would require repair. There was no cracking or substantial slope movement observed on the downstream slopes of the dikes that would be a concern for potential release of water from the ponds.
- The thermistor data available provides just over one year of monitoring and indicates that the dikes are not fully functioning as frozen core dams through the summer and early fall. DP3-A was fully thawed and the data for the other P-Area dikes indicates only the lower 0.5 to 1 m of the dikes remained below 0°C through the summer and early fall. To maintain the thermal integrity of the frozen cores of the dikes, the following should be implemented:
  - The water levels in the ponds should be reduced as much as possible in the winter to promote freezing of the dam cores. This would also increase the capacity within the ponds to manage water during the freshet, if necessary. The water levels should also be maintained as low as possible in the summer to reduce thermal warming due to water over the upstream toe of the dikes.

  - Where access is feasible, removal of snow from the water collection pond dikes is recommended to reduce the insulating effects of the snow, thereby allowing the temperatures of the core materials in the dikes and the foundations to drop as low as possible with the potential that temperatures could get cold enough to maintain frozen conditions throughout the following summer. Snow removal is more important if thermistor data indicates that temperatures within the dikes and/or foundation are warmer than expected.

- Make sure each thermistor cable is well marked so they can be located and maintained during the winter and are not damaged during snow removal operations. Consider adding data loggers to record the temperatures to facilitate data collection, particularly in the winter.
- Consider adding rockfill material to cover the till berm in P1, to protect the till and maintain its integrity if this berm is required for water management.
- If the P-Area ponds and associated dikes continue to be used by AEM, then it is recommended that they are added to the OMS manual for D-CP1 and D-CP5.
- AEM personnel should continue to conduct geotechnical inspections and document visual observations such as, cracking, slumping, and/or seepage. Thermistor data should continue to be collected, plotted and reviewed, and pond water levels should continue to be measured and tracked. Inspection reports should continue to be prepared for documentation. It is recommended that the frequency of visual geotechnical inspections be conducted weekly during freshet and monthly during the open water period.
- Continue to collect and pump back seepage water, as deemed necessary, in areas where seepage could impact downstream areas.

4.0 PERMANENT WATER COLLECTION POND DIKES, JETTIES, BERMS, AND CHANNELS

The permanent water management facilities for the Meliadine Gold Project will be constructed as the Project develops. This section presents a summary of the permanent water collection ponds and associated dikes, berms, and channels that had been constructed prior to the 2018 inspection, including Collection Pond 1 (CP1) and its associated dike (D-CP1), Collection Pond 5 (CP5) and its associated dike (D-CP5), Berm 3, Channel 1 (partially complete), Channel 2, Channel 3 (partially complete), Channel 5, and the saline pond.

The following subsections provide a description of the structures, visual observations, a summary of geotechnical instrumentation (if any exists), followed by recommendations.

4.1 Water Collection Ponds and Associated Dikes

At the time of the site visit in September 2018, two of the permanent water collection pond dikes had been constructed, D-CP1 and D-CP5. These dikes were constructed between October 2016 and July 2017. Both dikes are composed of rockfill and transition shells with a geomembrane liner anchored into a key trench within the permafrost foundation (soil or bedrock).

D-CP1 is approximately 600 m long with a maximum height of 6.6 m (Tetra Tech 2017g) and is located northeast of the P-Area, as shown in Figure 1. It is oriented approximately south–north with a slight inflection 200 m from the south abutment. D-CP1 was constructed across the outlets of lakes H6 and H17, which combine to form CP1. The CDA (2013) dam consequence classification for D-CP1 is *Significant* (Tetra Tech 2016a). A downstream collection sump and two channels were constructed approximately 5 m downstream of the D-CP1 toe to collect surface run-off and any possible dike seepage for pump back to CP1. CP1 is the final water management facility on site, and water from various parts of the site will be pumped to CP1 for treatment and discharge to Meliadine Lake.

D-CP5 is approximately 300 m long with a maximum height of 3.3 m (Tetra Tech 2017f) and is located southeast of the P-Area, as shown in Figure 1. It is oriented approximately southwest–northeast and was constructed across the south portion of Lake A54 such that the northern portion of the lake now forms CP5. The CDA (2013) dam consequence classification for D-CP5 is *Significant* (Tetra Tech 2016b). A small collection sump is located in a natural depression downstream of D-CP5 to collect surface run-off and any possible seepage through the dike for pump back to CP5. CP5 will be used seasonally for temporary water storage with active pumping to CP1.

4.1.1 Visual Observations

The inspection involved walking along the crests and toes of the dikes and examining the condition of the slopes of the dikes for visual signs of deformation and instability, cracking, and uneven surfaces. There was water in CP1 and CP5 at the time of the site visit, so it was not possible to walk along the upstream toes of the dikes. A photographic record of the inspection, with annotations added where appropriate, is included in Appendix A2.

Dike D-CP1

At the time of the inspection of D-CP1, the following general observations were made:

- Overall, the dike appeared stable, with no significant geotechnical concerns identified.
- Minor cracking and small settlement was observed along significant portions of the upstream slope and crest (e.g., Photographs 4 and 5 and Photographs 9 and 10, Appendix A2). The largest cracks were up to 2 to 3 cm wide. The cracking was generally in about the same condition to what was observed in 2017 with minor increases in the width and depth of some cracks.
- There was some cracking on the downstream crest near Stn 1+145 (Photograph 19). The cracks were wider and deeper than observed in 2017.
- There was no seepage observed from the downstream toe.
- The downstream collection channel appeared to be consistently graded to the downstream collection sump. The channel was generally dry, with only a very small amount of water ponded in the channel from approximately Stn 1+250 to the pond (Photographs 21, Appendix A2).
- Minor cracking was observed in the crests of the downstream collection sump berms that was similar to what was observed in 2017 (e.g., Photograph 26, Appendix A2).
- Jetty 1 was in good condition, no signs of instability (Photographs 27 to 29, Appendix A2). Some erosion marks on the slope due to wave erosion from historic high water levels.

Dike D-CP5

At the time of the inspection of D-CP5, the following general observations were made:

- Overall, the dike appeared stable, with no significant geotechnical concerns identified.
- Minor cracking was observed in a few locations on the upstream and downstream sides of the dike crest in the area between Stn.1+170 and 1+185 (e.g., Photographs 34, 35, 40, and 41, Appendix A2). The cracking on the downstream crest near Stn. 1+180 was similar to 2017. The rest of the cracking was not observed in 2017.
- There are two small holes near ground temperature cable VGTC-2 (Stn. 1+180) where there were failed drilling attempts during instrumentation installation.
- There were no signs of seepage from the downstream toe.
- There was a small pond of water in a low area downstream of the dike near Stn 1+170 with a pump in place but there was no active pumping at the time of the inspection (Photographs 42, Appendix A2). This water is likely due to surface runoff collecting in naturally low topography as D-CP5 was constructed across the southern portion of Lake A54.
- Jetty 5 is the causeway for the pump back station for CP5. Jetty 5 appeared stable with no significant geotechnical concerns identified (Photographs 43 and 45, Appendix A2).

Construction of D-CP1 and D-CP5 was completed in July 2017, and the dikes were transitioned from AEM's construction team to its engineering team at the end of 2017. AEM's engineering team conducted visual geotechnical inspections of the dikes between 14 June and 1 September 2018. Twelve inspections were completed and documented for both D-CP1 and D-CP5. The initial four inspections were completed within one week in June (14 to 21 June 2018). The remainder of the inspections were conducted approximately weekly from 5 July to 1 September, except for one missed inspection in mid-August. The inspections included observations of cracking and settlement, pond elevation, pumping activities and generally included photographs. AEM prepared visual tracking sheets for each dike by adding sketches of the locations of their observations to plan drawings of the dikes. No seepage was observed at either dike. The observations made by AEM staff were consistent with the observations during the 2018 annual inspection. Cracks and locations of settlement were also marked with spray paint in the field to monitor changes.

AEM noted that a channel had been constructed to connect the low areas of H17 and H6 so that water within the H6 area close to the dike could be drawn down further.

4.1.2 Geotechnical Instrumentation and Monitoring

Horizontal and vertical thermistors were installed in D-CP1 and D-CP5 between March and July 2017, as shown in Figures C4 to C7 in Appendix C. Plots of the thermistor data are provided in Appendix C. Thermistor data was provided up to 1 September 2018. As discussed in Section 2.0, the salinity of the groundwater at the Project site can result in freezing point depression of up to 3.2˚C at depth. The salinity of the groundwater increases with depth so the freezing point depression near surface is expected to be less, but frozen conditions may not occur at 0˚C.

Dike DCP-1

There were five horizontal thermistors installed in D-CP1 above the liner parallel to the key trench and five vertical thermistors installed upstream and downstream of the key trench. The locations of these instruments are summarized in Table 2. Horizontal thermistor data was provided from 21 March 2017 to 1 September 2018 and vertical thermistor data was provided from initial readings (varies between May and July 2017) to 1 September 2018.

There were also six settlement survey monuments installed over the liner crest in the central area of the dike as shown in Figures C4 and C5 in Appendix C2.

Table 3: Summary of D-CP1 Thermistor Locations

Instrument	Horizontal or Vertical (H or V)	Location	Additional Details
HGTC-1	H	Stn. 1+513 to 1+562	
HGTC-2	H	Stn. 1+254 to 1+304	
HGTC-3	H	Stn. 1+343 to 1+394	
HGTC-4	H	Stn. 1+432 to 1+482	
HGTC-5	H	Stn. 1+117 to 1+158	
VGTC-1	V	1+278	upstream of the liner and key trench
VGTC-2	V	1+280	downstream of the liner and key trench
VGTC-3	V	1+461	upstream of the liner and key trench
VGTC-4	V	1+460	downstream of the liner and key trench
VGTC-5	V	1+300	along slope upstream of the Phase 2 liner

Stn = Station (distance) along centreline of each dike from the starting reference point.

The following observations were made regarding the instrumentation readings collected for D-CP1:

- The horizontal ground temperature cable plots (Appendix C2) were indicating a warming trend in the base of the key trench in 2017. They cooled over the winter with most of the nodes approaching temperatures near -10˚C in early June 2018. Temperatures measured from early June to late August 2018 showed a warming trend of about 2 to 3˚C, indicating influence of ambient temperatures and/or ponded water within CP1. Winter readings were not collected between January and June 2018 for three of the instruments, HGTC-1, HGTC-3, and HGTC-5. All horizontal ground temperature cable nodes at the base of the key trench have remained frozen based on the data provided. Some of the nodes that are located on the downstream slope of the key trench and along the foundation of the dike below the downstream slope had temperatures that rose above 0˚C, particularly HGTC-5 which has beads that extend below and possibly downstream of the rockfill shell. These nodes have less cover and are therefore more influenced by ambient temperatures. Maximum temperatures may not have been reached as of the last readings provided for 1 September 2018.
- Vertical ground temperature cable plots (Appendix C2) indicate that the dike and foundation remained below 0˚C after November 2017 throughout the winter until about April/June of 2018. The maximum depth of 0˚C temperature readings ranged from approximately 1.2 m to 2.7 m in the summer and early fall of 2018. The final readings received (1 September 2018) identified the greatest depth of 0˚C temperature readings at 2.7 m observed in VGTC-01, located upstream of the liner and key trench. The maximum depth of 0˚C temperature readings may not have been reached as of the last readings on 1 September 2018. The maximum depth of 0˚C temperature readings in 2017 was equal to the depths measured in 2018 or 0.5 m lower, with the exception of VGTC-05 which had a maximum depth of 0˚C 1.2 m lower than what was measured in 2018. All the vertical thermistors indicate that the foundation and the lower 1 to 2 m of the dike (both upstream and downstream of the liner) remained below 0˚C during the reporting period.

- D-CP1 survey monitoring points M-1 to M-6 indicate a range of total vertical displacement between 29 and 40 mm between the baseline survey using the total station on 19 September 2017 to the last reading received for the reporting period on 13 August 2018. The range of total vertical displacement from the last reading in 2017 on 25 October to the last reading received for 2018 on 13 August was 18 to 25 mm. The maximum vertical displacement was observed at survey marker M-6 (station 1+510) and the minimum vertical displacement was observed at survey marker M-2 (station 1+230). The OMS manual indicates that total vertical settlement less than 120 mm is an acceptable (green) condition.

Dike D-CP5

Two horizontal thermistors are installed in the key trench approximately 250 mm above the liner along most of the length of the trench. Three vertical thermistors were installed upstream and downstream of the key trench and liner. The locations of these instruments are summarized in Table 4. There were also three settlement survey monuments installed over the liner crest in the central area of the dike as shown in Figures C6 and C7 in Appendix C2. Data provided for the horizontal thermistors is from April 2017 to September 2018. Data for the Vertical thermistors is from June 2017 to September 2018.

Table 4: Summary of D-CP5 Thermistor Locations

Instrument	Horizontal or Vertical (H or V)	Location	Additional Details
HGTC-1	H	Stn. 0+052 to 0+202	
HGTC-2	H	Stn. 0+164 to 0+304	
VGTC-1	V	Stn. 0+181	upstream of the liner and key trench
VGTC-2	V	Stn. 0+185	upstream of the liner and key trench
VGTC-3	V	Stn. 0+185	downstream of the liner and key trench

Stn = Station (distance) along centreline of each dike from the starting reference point.

The following observations were made regarding the instrumentation readings collected for D-CP5:

- The horizontal ground temperature cable plots initially indicated a warming trend after installation in the spring 2017. Beginning in January 2018, the data began showing a cooling trend. The cooling trend continued until about April 2018 and then started to warm as ambient temperatures increased. All thermistor nodes within the key trench remained at or below 0˚C throughout the reporting period (April 2017 to September 2018) and ranged from -3 to -10˚C. Maximum temperatures may not have been reached by the last readings on 1 September 2018.

- Vertical ground temperature cables VGTC-01 and VGTC-02 are located upstream of the liner and key trench in D-CP5. The data from these instruments indicates that the upstream dike fills were below 0˚C from October 2017 until April 2018. The maximum depth of temperatures above 0˚C extended approximately 3.5 m to near the interface between the base of the dike fills and original ground at VGTC-01 and 3.0 m at VGTC-02. The depth of 0˚C temperatures appeared to be stabilizing in September but may not have reached the maximum depth. In 2017, the maximum depth of 0˚C temperature readings was 4 m at VGTC-01 and 3.5 m at VGTC-02. Up to the last reading on 1 September 2018, the foundation below the dike remained below -1˚C and -2˚C at the location of VGTC-01 and VGTC-02, respectively.
- D-CP5 survey monitoring points M-1 and M-2 indicate total vertical displacement of approximately 20 mm between the baseline survey using the total station on 19 September 2017 to the last reading received for the reporting period on 21 July 2018. The range of total vertical displacement from the last reading in 2017 on 25 October to the last reading received for 2018 on 21 July was 9 to 12 mm. M-3 indicated a total vertical displacement of about 40 mm as of 25 October 2017. No additional readings were recorded for M-3 as it was reported as being destroyed. The OMS manual indicates that total settlement of less than 100 mm is an acceptable (green) condition.

AEM provided Golder with plots that are used to document the pond levels in CP1 and CP5. Pond elevations were taken from twice a day to once every one to three days from 25 May to 11 September 2018. The plots included the maximum allowable pond levels for pre-freshet, open water, pre-winter, and during a flood. The pond elevation in CP5 was above the maximum operating pond level from the start of monitoring on 5 June until 20 June 2018.

An operation, maintenance, and surveillance (OMS) manual, including an emergency response plan and emergency preparedness plan, was prepared for D-CP1 and D-CP5 (AEM 2018).

4.1.3 Recommendations

The following recommendations are provided regarding D-CP1 and D-CP5:

- Water volumes within containment ponds should be managed to the levels defined in the OMS, including maintaining the water level below the elevation defined for the end of October in the OMS Manual over the winter to promote freezing of the dikes.
- The D-CP1 sump and downstream collection channel should be emptied in the fall/early winter to refreeze the ground around these facilities. During the open water season, keeping the water level in the downstream channel and sump low will also reduce the potential for thaw of the ground and associated settlement.
- The open cracks and depressions observed in the dike crests should be filled with fine rockfill or sand to reduce the potential for infiltration into the dike that could lead to propagation of the cracks and cause additional thermal warming. These areas should be monitored following repair works to determine if these cracks and depressions reappear.

- The pipe ramp constructed out of sand upstream of D-CP1 near Stn. 1+140 is susceptible to erosion, and some erosion was observed since the 2017 inspection. It is recommended that the pipe ramp be covered with a coarser rockfill to protect it from erosion.
- Monitor the cracking observed in the D-CP1 downstream sump berms. Recontouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks that could lead to propagation of the cracks and warming of the permafrost and additional thaw settlement.
- Geotechnical inspections of the dikes should be conducted and documented following the schedule developed in the OMS Manual. Inspections were conducted in 2018 from June to September that generally met the requirements for weekly and monthly inspections laid out in the OMS Manual. Monthly routine inspections were conducted by Ms. Jennifer Pyliuk M.Eng., P.Eng., and weekly inspections were conducted by technicians from the engineering department. There were no inspections conducted from January to May 2018 due to snow cover. The OMS Manual indicates that daily inspections should be completed and documented using the same form as the weekly inspection, which were not completed in 2018. The OMS Manual does not indicate if there is seasonal variability to the frequency of documented inspections. It may be acceptable to seasonally vary the frequency of inspections, but this should be reviewed with the Engineer of Record (EoR) for the dikes and the OMS Manual should be updated, as required.
- It is a good practice to review the OMS Manual on an annual basis (e.g., the names and contact numbers for key personnel). The current OMS Manual is dated June 2018, so should be reviewed and updated as necessary around June 2019.
- The ground temperature cables and survey monitoring points should continue to be monitored following the schedule and procedures developed in the OMS Manual. The ground temperatures should be monitored to determine if the foundation remains frozen. Fluctuations of the temperature within the active layer in the dikes are expected; however, the foundation is designed to be maintained frozen.
- Where access is feasible, snow should be removed from the dike crests and slopes in the winter as this can help to reduce the insulating effects of the snow, thereby allowing the temperatures of the dike and foundation to drop as low as possible. Snow removal is more important if thermistor readings indicate warmer temperatures than expected.
- Survey marker M-3 on D-CP5 should be replaced, if possible, to continue monitoring liner settlement in this area of the dike.

4.2 Saline Pond

The saline pond is located east of DP3-A and was constructed during the third quarter of 2016. The saline pond was constructed to manage excess underground saline water before a long-term saline water disposal/treatment plan was finalized. During 2018, water was transferred from the saline pond to the P-Area for evaporation. At the time of the inspection, the permanent Saline Water Treatment Plant (SWTP) was under construction. AEM is planning to have the SWTP operational in 2019.

The saline pond was largely constructed by excavation within permafrost overburden and bedrock. A small berm approximately 1 to 2 m high was constructed around the excavation with a till core and rockfill cover to promote permafrost development in the original ground below the berm and keep surface water from the surrounding area from draining into the pond. The pond is designed to maintain the maximum pond elevation under the inflow design flood (1-in-100-year precipitation event) below original ground and below the level of CP5 to minimize the potential for seepage out of the saline pond.

4.2.1 Visual Observations

The inspection involved walking along the crest of the saline pond perimeter berm, examining the condition of the berm for visual signs of deformation and instability, cracking, uneven surfaces, and seepage. A selection of photos from the inspection are included in Appendix A2.

At the time of the inspection of the saline pond, the following general observations were made:

- Overall, the pond and perimeter berm appeared stable, with no significant geotechnical concerns identified.
- There was water in the pond at the time of the site visit that was well below the top of the bedrock excavation (Photograph 46, Appendix A2).
- Water was ponded between DP3-A and the northwest perimeter of the Saline Pond (Photograph 50, Appendix A2). There was more water ponded than in 2017.
- Cracking and settlement were observed in the perimeter berm in several locations on the upstream and downstream crest (Photograph 46, 47 and 48, Appendix A2). Cracking on the northwest perimeter berm had increased slightly from 2017. Cracking observed on the southwest and southeast sections of the perimeter berm were not observed in 2017.
- There is an area near the upstream toe of the northwest perimeter berm that appears to have settled. This area was observed in 2017 and did not appear to have changed substantially at the time of the 2018 inspection (Photograph 49, Appendix A2). Seepage water from DP3-A has been observed to pond against the north side of the Saline Pond berm and may seep into the berm. During the 2017 inspection, AEM also indicated that there is a fault in this area and surface water sometimes seeps into the pond through the northwest section of the perimeter berm (downstream of DP3-A). This seepage could be causing thawing of the permafrost in the foundation resulting in settlement and cracking within the berm.
- There was no seepage into the Saline Pond observed during the inspection.

4.2.2 Recommendations

The following recommendations are provided regarding the saline pond for the time it is in operation:

- Consideration for filling in the cracks with fine rockfill, recontouring, and re-compacting the slopes and crests may be warranted to reduce the potential for infiltration into the berms that may increase the cracking and settlement.
- Monitor the downstream side of the perimeter berm for ponding water and consider diverting it or pumping it so it does not seep into the saline pond and warm the foundation below the berm.

4.3 Diversion Channels and Berms

Diversion Channel 1, 2, 3, and 5 were inspected and Berm 3. The channels were constructed by excavating a trench, placing woven geotextile to line the excavation, and then placement of riprap (coarser rocks) over the fabric to line the channels.

Channel 1 is designed to move water from Pond H13 to CP1 and extends from Culvert 2 to Pond H9 along the north and east sides of Portal #2. Channel 1 had been completed from Lake H9 to just west of Culvert 16. Channel 1 will be approximately 493 m long when it is complete with a base width of 3 m.

Channel 2 is located along the northern end of the main mine site industrial pad and is approximately 270 m long with a base width of 1 m. During construction and operation, contact water from the plant site area will naturally flow or be diverted into Channel 2, which in turn will flow into ponds H15E, H15, H14, H13, H12, H9, H8, and eventually into CP1.

Channel 3 is designed to direct seepage and run-off water from the future tailings storage facility (TSF) into future collection pond CP3. Channel 3 is located northwest of the operational landfill and runs along the southwestern boundary of the TSF. Most of Channel 3 had been constructed at the time of the site visit, except for a small section at the outlet end near future CP3. Channel 3 will be approximately 619 m long when complete with a base width of 1 to 2 m.

Channel 5 and Berm 3 are located west of CP5 and are designed to divert water from the pond A12 catchment area into CP5 so that this water does not flow into Tiriganiaq Pit 1. A selection of photos from the inspection are included in Appendix A2 (Photographs 67 through 76). Channel 5 is the main water diversion structure; Berm 3 is only required to temporarily retain water under an extreme rainfall event when the water level in CP5 is temporarily high (Tetra Tech 2016d). Channel 5 is approximately 429 m long with a base width of approximately 3 m. Berm 3 is approximately 315 m long with a maximum height of about 2.8 m. Berm 3 consists of a till core, a foundation key trench backfilled with till, and a cover layer constructed out of 600 mm minus esker material. The design specified run-of-mine rockfill for the cover; however, this material was not available at the time of construction.

4.3.1 Visual Observations

Channel 1 and Culvert 16

The inspection of Channel 1 involved walking along the southern boundary of the channel from the western extent to the outlet at the east, with periodic crossing to the northern boundary where feasible. A selection of photographs from the inspection are included in Appendix A2 (Photographs 51 to 56). There was water ponded in several locations along the channel, likely coinciding with the ponds that it was constructed through (H9 to H12). There was water ponded upstream of the inlets to Culvert 16 as the inverts of the culverts were elevated. If the channel invert remains below the invert of the lowest culvert, water will have to pond in the area prior to flowing through the culverts. There was cracking and some settlement along the edges of the channel (e.g., Photograph 52). The movement may be slumping of the riprap over the fabric or may be due to thaw settlement in the permafrost within the edges of the channel.

Channel 2

Channel 2 was inspected by walking from the start of the channel at east end to the outlet at the west end. A selection of photos from the inspection are included in Appendix A2 (Photographs 57 through 62). The slope of the channel base is not consistent and some pooling of water and deposition of sediment in lower areas was observed which is consistent with previous observations. Ponded water may infiltrate into the channel base but is not expected to be substantial. No geotechnical concerns associated with Channel 2 were identified.

Channel 3

Channel 3 was inspected by walking from the start of the channel at the east end to the northwest end. Most of the construction of Channel 3 had been recently completed at the time of the inspection, except the northwest section (Photograph 66). A selection of photos from the inspection are included in Appendix A2 (Photographs 63 through 66). The access road to the future location of CP3 runs along the western boundary of Channel 3 (Photograph 64 and 65). Water was ponded in the northwestern section of the channel which is the lowest elevation and close to the outlet to CP3. No geotechnical concerns associated with Channel 3 were identified.

Channel 5

Channel 5 was inspected by walking the southern crest from near the northwestern end of the channel to the outlet near CP5. A selection of photos from the inspection are included in Appendix A2 (Photographs 67 to 71). Overall Channel 5 appeared stable, with no significant geotechnical concerns identified. There was some cracking observed adjacent to Channel 5 (Photographs 67 and 71, Appendix A2). The most substantial cracking was observed at the northwestern end of the channel where lakes H12 and H13 were located. Water was ponded within the channel in this area (Photograph 71). There was some shallow ponding of water in the channel near the outlet to CP5 and near station 0+220.

Berm 3

Berm 3 was inspected by walking along the crest and slopes examining the condition of the berm for visual signs of deformation and instability, cracking, or uneven surfaces. A selection of photos from the inspection are included in Appendix A2 (Photographs 72 to 78).

- Overall, Berm 3 appeared stable with no significant geotechnical concerns identified.
- Water was ponding near the upstream toe of Berm 3 near station 0+100 (Photograph 74, Appendix A2).
- Erosion and minor cracking observed on upstream and downstream slopes (e.g., Photographs 76 to 78).
- Water was ponded over the tundra in some areas downstream of the dam, but there was no seepage observed from the downstream slope.

4.3.2 Recommendations

The following recommendations are provided regarding the diversion channels and Berm 3:

- Monitor the cracking adjacent to Channel 1 and Channel 5. Re-contouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks, and reduce the potential for warming of the permafrost and additional thaw settlement and cracking. Check as-built slopes of Channel 1 in the areas of cracking to confirm constructed to design (3H:1V), or as otherwise approved by the design engineer; steeper slopes may be the cause of the movement. Reducing the amount and duration of water ponding in Channel 5 will help reduce thermal degradation of the surrounding permafrost and cracking.
- If the bottom of Channel 1 remains below the inlets for Culvert 16, consider lowering the invert of the lowest culvert or adjust the invert of the channel, if possible, so that water will not need to pond in the channel before flowing through the culverts.
- According to the design for Channel 5 and Berm 3 (Tetra Tech EBA 2016d), Channel 5 is supposed to be able to handle run-off flows except for an extreme rain event and Berm 3 is only intended to temporarily retain water when the water level in CP5 is high due to an extreme rain event. However, at the time of the 2017 site visit, water had overflowed Channel 5 and was ponded against Berm 3. There was water ponded against Berm 3 during the 2018 inspection as well, but a much smaller amount. Ponding upstream of Berm 3 should be monitored to determine how much and how often ponding occurs and if Berm 3 can perform as required with the ponding.
- The Berm 3 cover materials are susceptible to erosion and some minor erosion was observed during the 2018 inspection. Erosion of the slopes should be monitored and consideration should be given to placing coarser material on Berm 3 to reduce the potential for erosion if it becomes substantial.

5.0 SITE ROADS, CULVERTS, AND TIRIGANIAQ ESKER AND WESMEG BORROW AREA

This section summarizes the observations made during the 2018 geotechnical inspection regarding the main site roads and associated culverts, and the Tiriganiaq Esker and Wesmeg Borrow Area roads and facilities. Appendix A3 contains selected photographs taken during the inspection. The following is a list of the roads, water management structures, and facilities inspected:

- landfill access road and to future TSF area, including Culvert 1 (Photographs 1 to 3, Appendix A3)
- main site pad area roads, including Culverts 2, 3 and 4 (Photographs 4 to 12, Appendix A3)
- main site water intake access road (Photographs 13 to 16, Appendix A3)
- emulsion plant pad access road and Culvert 13 (Photographs 17 to 22, Appendix A3)
- Tiriganiaq Esker access road (Photographs 23 and 24, Appendix A3)
- magazine storage area and access road (Photograph 25, Appendix A3)
- Wesmeg access road, Wesmeg Borrow area and vent raise (Photographs 26 to 31, Appendix A3)
- CP4 access road (Photograph 32, Appendix A3)

5.1 Visual Observations

5.1.1 Site Roads and Culverts

At the time of the site visit, the site roads were generally in good condition. As the site is in active construction, roads were in various stages of construction/operation. The roads appeared to generally be of adequate width with pull outs where required to allow vehicles to safely pass. The heights of the road fills were such that berms were not required. Many of the roads appeared to have been constructed using a combination of sand and gravel obtained from esker borrow areas, rockfill, and crushed aggregate. Normal maintenance of the roads should be anticipated. No geotechnical concerns were identified during the inspection.

There were four permanent water management culverts in place through road fills at the time of the site visit: Culverts 1, 2, 3, and 4. A summary of the culverts inspected, general observations, and any recommendations is provided in Table 5.

Table 5: Summary of Site Culverts Inspected

Access Road	Culvert No.	Culvert Description	Visual Observations
Operation Landfill Access Road (and future TSF)	1	2 × 1000 mm CSP	Culverts were in good condition (Photographs 2 and 3, Appendix A3). There was a small pool of water below the upstream ends of the culverts, but no flow through the culverts. The inlets of the culverts were elevated above the ground upstream which will allow some water to pond against the road prior to flowing through the culverts. Culverts appeared to have a sufficient thickness and appropriately sized cover material.
Service Road on west side of Portal #2 and Crusher Ramp	2	4 × 1200 mm CSP	Culverts were in good condition (Photographs 6 and 7, Appendix A3). There was some water ponded in the area around the downstream ends of the culverts, but no water flowing through the culverts at the time of the site visit. Culverts appeared to have appropriately sized cover material.
Service road on west side of CP1	3	3 × 600 mm CSP	Culverts were in good condition (Photographs 8 and 9, Appendix A3). The downstream ends of the culverts were partially submerged in a small pool of water within CP1, but there was no flow through the culverts at the time of the site visit. Culverts appeared to have appropriately sized cover material.
	4	1 × 600 mm CSP	Small amount of damage to upstream end of the culvert (Photographs 10 to 12, Appendix A3), which isn't expected to substantially reduce flow capacity and had not changed from 2017. No flow through the culvert. Culvert appeared to have appropriately sized cover material.

Note: 1 × 600 mm = the number of culverts × the diameter of the culvert.

CSP = corrugated steel pipe.

5.1.2 New Emulsion Plant and Access Road

The emulsion access road was constructed in 2017. The following are some of the general observations:

- The road appeared to generally be of adequate width and had pull outs to allow vehicles to safely pass. The height of the road fill was such that berms were not required.
- The road appeared to have been constructed using esker sand and gravel material, which may be susceptible to erosion. The surface of the road was in variable condition. The northern section, past the laydown area, had a fairly rough surface. The road fills were thicker south of the laydown area and the road surface was smoother. There were straw logs in place in a few locations adjacent to the road, for sediment control. AEM representative indicated that water was flowing over the road during the freshet and straw logs were placed to capture suspended solids.
- A culvert was installed through the road near the laydown area, but there was no flow at the time of the site visit. Straw logs had been placed to control erosion and suspended solids in the flow.
- There was some minor cracking observed in the crest of the road in a couple of locations.
- During construction, some areas of the tundra adjacent to the road were stripped and water was ponded along the road in several of these areas during the 2018 inspection. Ponded water can cause degradation of permafrost leading to settlement and additional road maintenance.
- Culvert 13 was installed at the south end of the road near H15E. There was some minor damage to the outlet of the right culvert (looking downstream).

5.1.3 Wesmeg Borrow and Tiriganiaq Esker Area Facilities

The magazine storage, Wesmeg Borrow, and vent raise areas were inspected, as well as, the access roads to these facilities. A selection of photographs taken during the inspection are provided in Appendix 3 (Photographs 23 through 32).

The Wesmeg access road was constructed by borrowing material on either side of the road leaving disturbed trenches along the edges of the road. During the 2018 inspection, there was an area adjacent to the Wesmeg access road, northeast of the magazine storage area, that was disturbed, and water was ponded against the road (Photograph 27, Appendix A3). There was a large pond of water against the road where it crosses low topography north of Lake B33A (Photographs 28, Appendix A3). The design report for the Wesmeg Road (Tetra Tech EBA 2016e) indicates that a culvert was planned for this location.

The following are some of the general observations:

- The magazine storage area and blast guard berms were inspected and there were no signs of erosion or cracking (Photograph 25, Appendix A3). No geotechnical concerns associated with the magazine storage area were identified.

- Cracking and erosion were observed in the materials stockpiled at the Wesmeg Borrow area (Photograph 29, Appendix A3). Straw logs had been placed downstream to control the sediment. There are no geotechnical concerns with the erosion, but remediation of the area is required for longer term sediment control. Rehabilitation of the Wesmeg esker has been scheduled by AEM to be completed after construction of the vent raise.
- A small rockfill pad had been constructed at the Wesmeg vent raise with a low area and a berm on the west side (Photograph 30, Appendix A3). Two steel pipes were installed through the access road to the pad for water management (Photograph 31, Appendix A3). There was no flow at the time of the site visit.

5.2 Recommendations

The following are recommendations for the site roads and culverts and the Tiriganiaq and Wesmeg Borrow areas:

- Consider lowering the lower culvert at Culvert #1 so that water won't pond against the road prior to flowing through the culverts.
- The culvert planned for where the Wesmeg Borrow access road crosses low topography, north of Lake B33A, should be installed if the road is blocking natural drainage that is causing more water to pond that could lead to permafrost degradation and settlement or cracking in the road.
- The Wesmeg Borrow area should be recontoured and either capped with a coarser material or some other form of reclamation to protect against erosion.
- Culverts should be installed in areas of the emulsion plant road where water was flowing over the road in 2018.
- If erosion occurs in the esker sand material used to construct the emulsion plant road, rockfill should be placed to cap the road and reduce erosion. Placement of a gravel road capping may also be beneficial to improve the road surface, particularly over the northern section of the road.
- It is recommended that the disturbed areas adjacent to the Emulsion Plant and Wesmeg Borrow access roads be regraded so that water does not pond adjacent to the road and thaw the permafrost around and under the road which could lead to settlement.
- Regular monitoring and maintenance of the roads should be conducted.

6.0 TEMPORARY ORE AND WASTE STOCKPILES

The ore and waste rock storage area is located east of the P-Area. The rock and ore (high grade and low grade) piles are relatively small during the development stage of the mine. A selection of photographs from the inspection are provided in Appendix A4 (Photographs 1 through 9).

Ore and waste materials removed from the underground development are transported to surface and placed in stockpiles. The majority of waste rock is crushed into various sizes for use in construction. There were also stockpiles of crushed materials in this area. Berms were in place around the top benches of the piles and there was a small pond of water observed in the middle of the bench of the Waste Rock Pile (Photograph 5, Appendix A4). Some cracking was observed in one area of one of the high grade ore stockpiles that looked to be shallow slumping of material on the slope likely due the slope being locally over steepened. There was no active placement on this pile and material had been placed to block access on the ramp so there is no concern with the cracking (Photograph 4, Appendix A4). If placement was to restart on this pile, the slope in the area of cracking should be resloped to be consistent with the slopes around the remainder of the pile.

No geotechnical concerns related to the stability of the stockpiles were identified.

7.0 OTHER MELIADINE FACILITIES

This section contains the observations and recommendations from the 2018 geotechnical inspection of other Meliadine facilities including: the landfarm, underground Portal No. 1, underground Portal No. 2, exploration landfill, operations landfill, fuel storage areas, and industrial and mine site pads. A general description of each facility and the visual observations from the 2018 inspection are provided in Section 7.1 and recommendations for the facilities are provided in Section 7.2.

A selection of photos from the inspection are included in Appendix A5. Photograph 1 provides a Google Earth Image overview of the mine facilities.

7.1 Visual Observations

7.1.1 Landfarm

The new landfarm is located at the southeast corner of the industrial pad area and west of the water treatment plant (Photograph 1, Appendix A5) and replaces the exploration landfarm (Section 8.1.3) which will be decommissioned. The landfarm was constructed in 2017 and includes perimeter containment berms constructed mainly out of esker sand and gravel material, 30 mm minus liner bedding, geomembrane liner with geotextile placed above and below, 30 mm minus liner cover and 200 mm minus rockfill final cover. There is a sump located in the southeast corner of the facility. The slopes of the berms appeared to be approximately 2.5 horizontal to 1 vertical as per the design (Tetra Tech 2017b). There were no signs of erosion, cracking, or settlement. No geotechnical concerns were identified.

At the time of the 2018 site visit, AEM had set up a lined temporary screening area on the west side of the landfarm. Large cobbles and boulders were being screen out for use elsewhere on site and the fine material was being placed back in the landfarm.

A selection of photos from the inspection are included in Appendix A5 (Photographs 2 through 11).

7.1.2 Underground Portal No. 1

Underground Portal No. 1 is located southwest of P3 (Photograph 1, Appendix A5). At the time of the inspection, Portal No. 1 had been constructed and was in use. A selection of photos from the inspection are included in Appendix A5 (Photographs 12 through 15).

A small excavation and corrugated culvert are used to connect the underground ramp to surface. Portal No. 1 was observed from the surface only, with observation of the small bedrock cut face above the culvert. A rockfill berm was also in place around the perimeter of the portal excavation. The toe of the rockfill perimeter berm was close to the crest of the rock face in some locations and there was evidence of ravelling of rockfill into the cut; however, the corrugated culvert protects the access to the portal, so there is no safety concern. There was some minor erosion observed on the surface of the backfill material adjacent to the portal (Photograph 12, Appendix A5). The condition of the portal area was similar to 2017 and there were no other geotechnical concerns identified at the time of the inspection.

7.1.3 Underground Portal No. 2

Underground Portal No. 2 is located northwest of the P-Area, on the west side of the access road from Portal No. 1 to the main camp site (industrial pad) (Photograph 1, Appendix A5). Waste rock was being removed from the portal. At the time of the inspection, backfill was in progress around the sides of the corrugated steel culvert forming the entrance to Portal No. 2. A selection of photos from the inspection are included in Appendix A5 (Photographs 16 through 20).

A small excavation and corrugated culvert are used to connect the underground ramp to surface. Portal No. 2 was observed from the surface only, with observation of the small bedrock cut face and perimeter berm. Rock bolts and mesh were in place over most of the rockfill cut. There was some evidence of ravelling of rockfill into the excavation; however, the catch berms appeared to generally be sufficient to allow safe backfill placement round the culvert. The slopes above active backfill placement should be regularly monitored for potential rock fall hazards. The culvert protects access to the portal during operations. Water was observed ponding in some areas around the perimeter of the portal (outside the perimeter berm). AEM indicated that water management facilities will be constructed once the backfill is complete.

7.1.4 Exploration Landfill

The exploration landfill is located southwest of Portal No. 2 and northwest of the P-Area (Photograph 1, Appendix A5) and is within the future Waste Rock Storage Area 1 (WRSA1) footprint. The exploration landfill had been decommissioned and the new operation landfill was in use.

The exploration landfill is located on gently sloping ground and is contained on three sides by berms and by high ground on the fourth (south) side. The berms appeared to be constructed with esker materials that contained substantial amounts of sand and gravel. The slopes appeared to be approximately 2.5 horizontal to 1 vertical. It appeared that esker material had been used to cover the top of the landfill as part of decommissioning. Some wood debris was still evident protruding through the cover. A selection of photos from the inspection are included in Appendix A5 (Photographs 21 through 26).

Cracking was observed on the downstream slopes of the containment berms, similar to the 2017 inspection. The cracking appeared to be largely due to translational slumping of the berm materials on the slope (e.g., Photographs 22 and 24, Appendix A5). There was water ponded in a small depression adjacent to the access road and south side of the landfill, but there was no ponded water on the surface of the landfill and no seepage observed.

7.1.5 Operation Landfill

The operation landfill is located northwest of Portal No. 2 and within the northeast corner of the future Waste Rock Storage Facility 1 footprint (Photograph 1, Appendix A5). The operation landfill was constructed in 2017. At the time of the 2018 site visit, a substantial portion of the original operation landfill was full and an expansion had been constructed on the south side of the original landfill. A selection of photos from the inspection are included in Appendix A5 (Photographs 27 through 34).

The operation landfill is located on sloping ground and is contained by perimeter berms. The berms and floor were constructed with esker materials that contained substantial amounts of sand and gravel. The slopes appeared to match the design of approximately 2.5 horizontal to 1 vertical for the exterior slopes and 2 horizontal to 1 vertical for interior slopes. The slopes of the expansion portion of the operation landfill appeared to be steeper than the original berms. The berm crests and slopes were in good condition, except for the toe of the northeast corn of the facility where water was observed to be ponding on the tundra downstream and there was some erosion and potentially slumping on the slope (Photograph 30, Appendix A5). The sand and gravel material may be susceptible to erosion. If erosion is observed, a coarser rockfill layer should be placed over the exterior slopes and berm crests to protect against erosion. As WRSF1 is constructed, the landfill will become surrounded by rockfill.

7.1.6 Fuel Storage Containment Areas

There are two fuel storage areas at the main mine site, the mine site fuel area and the industrial fuel storage area. The mine site fuel storage is located south of the west end of D-CP1 and north of the saline pond and the Industrial fuel storage area is located northwest of the landfarm (Photograph 1, Appendix A5). The fuel storage areas are lined perimeter berm facilities to provide secondary containment for the fuel tanks. The floors of the facilities are graded to a drainage sump to collect surface runoff water.

The mine site fuel storage area was constructed in 2017. There are two tanks: 3 million litres and 250,000 litres contained in the facility. The industrial site fuel storage area was constructed in 2017 and 2018. There are two tanks: 6 million litres and 250,000 litres contained in the facility.

The interiors of the facilities are lined with HDPE liner with non-woven geotextile placed above and below. The dike slopes appeared to be approximately 2 horizontal to 1 vertical, as per the design (Tetra Tech and WSP Canada Inc. 2017). There were minor signs of sloughing in the liner cover materials, but no other geotechnical concerns identified. There was no ponded water or seepage observed. A selection of photos from the inspection are included in Appendix A5 (Photographs 35 through 40).

7.1.7 Main Site Pads

At the time of the 2018 inspection, the northern portion of the industrial pad was mainly complete, but the southern portion of the industrial pad was under construction. Various facilities were also under construction on the pads. In addition to the main industrial pad there are several other smaller pads that have been constructed for various mine site facilities that were inspected, such as, the effluent water treatment plant pad, incinerator pad, east air intake pad, temporary cyanide storage pad and emulsion plant and storage area pads.

Inspection of the pads involved walking along crests and toes, examining the condition of the slopes for visual signs of erosion and instability, cracking, or uneven surfaces. A selection of the photographs taken during the inspection are provided in Appendix A5 (Photographs 41 through 58).

The pads on site have been constructed using a combination of rockfill and esker sand and gravel obtained from borrow areas. A surface layer of crushed aggregate was observed in some areas (e.g., Photographs 43 and 47, Appendix A5). The height of the pad varies, based on topography. The slopes of the edges of the pad ranged from approximately 2.5 to 3 horizontal to 1 vertical, and appeared stable.

Normal maintenance of the surface of the pads, in particular areas with heavier traffic (e.g., roads), should be anticipated, as well as maintenance of slopes, particularly where pads have been constructed with esker materials that are more prone to erosion.

The following is a summary of the key observations from the pad inspections:

- Similar to the 2017 inspection, during the 2018 inspection, there was visual evidence of erosion of the north slopes of the industrial pad (Photographs 41 and 42, Appendix A5). The erosion had increased from 2017. There was also some erosion and cracking observed at the crests and on the slopes of some of the other pads that was not observed in 2017 (e.g., incinerator and emulsion plant pads Photographs 47 and 54, Appendix A5).
- There was a relatively large pond of water located west of the industrial fuel storage area (Photograph 46, Appendix A5). The slopes around the ponded water appeared to be approximately 3H:1V and there was no instability observed. AEM has scheduled this area to be filled and graded with fill materials as part of finalizing the Industrial Pad construction during 2019.
- A pipe berm on the south side of the effluent water treatment plant pad had been constructed out of sand that is susceptible to erosion (Photograph 50, Appendix A5).
- There was an area of the emulsion storage pad (located near the emulsion plant pad), that had large ruts from where a loader had gotten stuck (Photograph 58, Appendix A5). The surface of the pad appeared to be finer esker material, no rockfill surfacing material had been placed. This surface will likely continue to cause trafficking issues during periods of high precipitation. The emulsion plant pad surface was in better condition, likely due to recent grader work, but was also observed to have finer material at surface that may cause trafficking issues during high precipitation. There was some ditching in place around the south and eastern perimeters of the emulsion plant pad to help with water management.

7.2 Recommendations

The following are recommendations for the Meliadine Mine site facilities summarized in Section 7.1:

- The slopes of the operation landfill should be monitored, particularly the northeast corner where water was observed to be ponded and there appeared to be some slumping on the berm slope. Recontouring of the slope in this area will reduce the potential for future erosion.
- The north slopes of the industrial pad should be recontoured and a coarser surfacing layer should be placed on the slopes where erosion is substantial.
- A coarser rockfill cover should be placed over the pipe berm constructed out of sand on the south side of the effluent water treatment plant to protect against erosion.
- AEM indicated that ground control engineers routinely conducted and documented inspections of the rock slopes surrounding Portal No. 2 during backfill placement around the culvert at the entrance to the portal. Monitoring of the slopes, including loose rockfill material above the slopes should continue during backfill placement around the culvert.

- Snow management around and above Portal No. 1 and 2 may be advisable, especially prior to freshet, to reduce the potential for larger surface water inflows entering the underground.
- Where erosion occurs on the slopes of the various site pads, coarser rockfill should be placed over the slopes and crests to reduce the potential for further erosion.
- A gravel or rockfill surfacing layer may be required at the emulsion plant and storage pads if trafficking issues continue.
- The exploration landfill will eventually be covered by WRSA1, so the cracking and erosion on the slopes is not a substantial concern. Placement of a coarser rockfill layer over the decommissioned exploration landfill could be considered to reduce cracking and erosion in the short term.

8.0 EXPLORATION CAMP AND ACCESS ROAD

The exploration camp site was the first area of the project that was developed and at the time of the site visit it was still being used. The new camp and office facilities at the main mine site had been constructed and were in use; however, due to the number of people on site the exploration camp and office facilities were still being used.

The exploration site was inspected including the site pad, genset containment facility, fresh water intake, diffuser access, landfarm, fuel storage, and access road. The following sections provide a summary of the observations and recommendations relating to the exploration camp and access road.

A general description of each facility and the visual observations from the 2018 inspection are provided in Section 8.1. Recommendations for the facilities are provided in Section 8.2.

8.1 Visual Observations

8.1.1 Exploration Camp Pad, Water Intake, and Diffuser Access

The exploration camp site is located on a peninsula on the west shore of Meliadine Lake. The exploration pad has primarily been constructed with esker sand and gravel material; however, small localized portions of the slopes contain coarser grained particles. The thickness of the pad varies based on topography; however, it is generally relatively thin. The slopes appeared to be approximately 2 to 2.5 horizontal to 1 vertical. During the 2018 inspection, the slopes generally appeared stable and in a similar condition to 2017. There was some surface erosion on southeast side of the exploration camp pad that was in a similar condition to what was observed in 2017 (Photograph 3, Appendix A6). Sand had been used to cover some cables on the south side of the pad that is susceptible to erosion (Photographs 4, Appendix A6). At the time of the inspection, an excavator was removing contaminated material from a fuel spill on the south side of the camp (Photograph 5, Appendix A6). There was some disturbance to the tundra observed on the south side of the exploration camp that may have been due to boat access to the lake (Photograph 9, Appendix A6). Trafficking over the tundra directly should be avoided. A new genset containment facility was under construction at the time of the site visit at the northeast end of the site (Photographs 10 and 11, Appendix A6). The containment berms appeared to have been constructed out of esker materials that could be susceptible to erosion, but otherwise the berms were in good condition. The facility appeared to be lined and there was a drain in one corner of the facility. There were no other geotechnical issues identified for the exploration camp pad. A selection of photos from the inspection are included in Appendix A6 (Photographs 1 through 11).

A short access road extends to the north from the exploration camp pad to the edge of Meliadine Lake, to provide vehicle access to the fresh water intake pump house and pipeline. No geotechnical concerns were identified. A selection of photographs from the water intake access inspection are included in Appendix A6 (Photographs 12 through 15).

The diffuser access road starts at the water intake access road and runs east to Meliadine Lake. The road appeared to have been constructed with esker materials and there was cracking along the edges of the road along most of its length. Cracking was observed along more of the road than in 2017 and some of the cracks observed in 2017 were wider. The cracking is not a significant concern and no other geotechnical issues were identified. A selection of photographs from the diffuser access inspection are included in Appendix A6 (Photographs 16 through 21).

8.1.2 Exploration Camp Access Road

At the time of the site visit, the exploration road was generally in good condition and appeared to have been constructed with esker materials. There was some erosion observed on the slopes of the road (e.g., Photographs 28 and 29, Appendix A6) that had increased from 2017. There were four culverts installed through the road, and observations from the inspection are summarized in Table 6. A selection of photographs from the diffuser access inspection are included in Appendix A6 (Photographs 22 through 37).

Table 6: Exploration Camp Access Road Culvert Summary

Culvert Location	Culvert Description	Comments/Recommendations
North side of camp	1 × 450 mm HDPE corrugated	Upstream end of culvert appears to have been buried within the exploration camp pad (Photographs 22, Appendix A6). No flow.
North side of camp	1 × 450 mm HDPE corrugated	Upstream end of culvert appears to have been buried within the exploration camp pad (Photographs 23, Appendix A6). No flow.
North side of camp	1 × 600 mm CSP	Culvert in good condition, no obstructions, no flow, minor amount of water pooled in base of culvert and on ground downstream of outlet. Esker material surrounding culvert. Upstream and downstream slopes are not armoured. (Photographs 24 and 25, Appendix A6).
West of camp near Lake J1	1 × 600 mm HDPE corrugated	Some deformation of haunch of culvert under road. Minor flow. Upstream inlet to culvert armoured with rockfill and outlet partially armoured. (Photographs 30 and 31, Appendix A6).
West of camp near Lake J1	1 × 600 mm HDPE corrugated	Culvert in good condition. Upstream inlet to culvert armoured with rockfill that extends into culvert. Downstream end of culvert partially blocked with material that should be cleared out. (Photographs 32 and 33, Appendix A6).

Note: 1 ×__ mm = the number of culverts × the diameter of the culvert.

CSP = corrugated steel pipe.

8.1.3 Fuel Storage Area and Landfarm

The fuel storage area, landfarm, and core storage pad are located along the north side of the exploration camp access road, approximately 0.9 km west of the camp. A selection of photos from the inspection are included in Appendix A6 (Photographs 38 through 48).

The exploration bulk fuel storage tanks contain jet fuel and diesel. At the exploration camp, there is a small tank with gasoline. All tanks are double lined and self-contained. The tanks are located on raised pads, constructed with esker sand and gravel. There is no liner or berm surrounding the tanks. The exploration fuel storage pad was generally in good condition; however, some minor cracking was observed along the east crest due to settlement (e.g., Photograph 39, Appendix A6). The cracking is not a significant geotechnical concern.

The exploration landfarm consists of an above-ground bermed containment area, which appears to have been constructed of esker sand and gravel, with a 60 millimetre HDPE geomembrane liner and nonwoven geotextile beneath the liner. The liner surface has been covered with a layer of sand and gravel. Contaminated soils have been placed within the bermed area. There was no water ponding within the facility, but there was damp soil indicating that water sometimes ponds, as was observed during the 2017 inspection. It is understood that water samples are periodically collected and, if necessary, the water is treated prior to discharge. There was no seepage or ponded water downstream of the containment berms observed at the time of the inspection; however, there were some indications of minor erosion on the slopes that could be due to previous seepage. Vegetation had grown over most of the downstream slopes of the berms.

It is understood that AEM intends to decommission the exploration landfarm now that the new landfarm at the main site is operational (Section 7.1.1). When the exploration landfarm is decommissioned, it is anticipated that some cleanup of the foundation soil, and containment berms material will be necessary. Until such time that the exploration landfarm is decommissioned, AEM should try to minimize the amount of water contained within the exploration landfarm.

The core storage pad is located north of the landfarm. The pad slopes generally looked stable; however, there were some fairly large cracks along the east crest (e.g., Photograph 49, Appendix A6).

8.2 Recommendations

The following are recommendations for the exploration camp and access road:

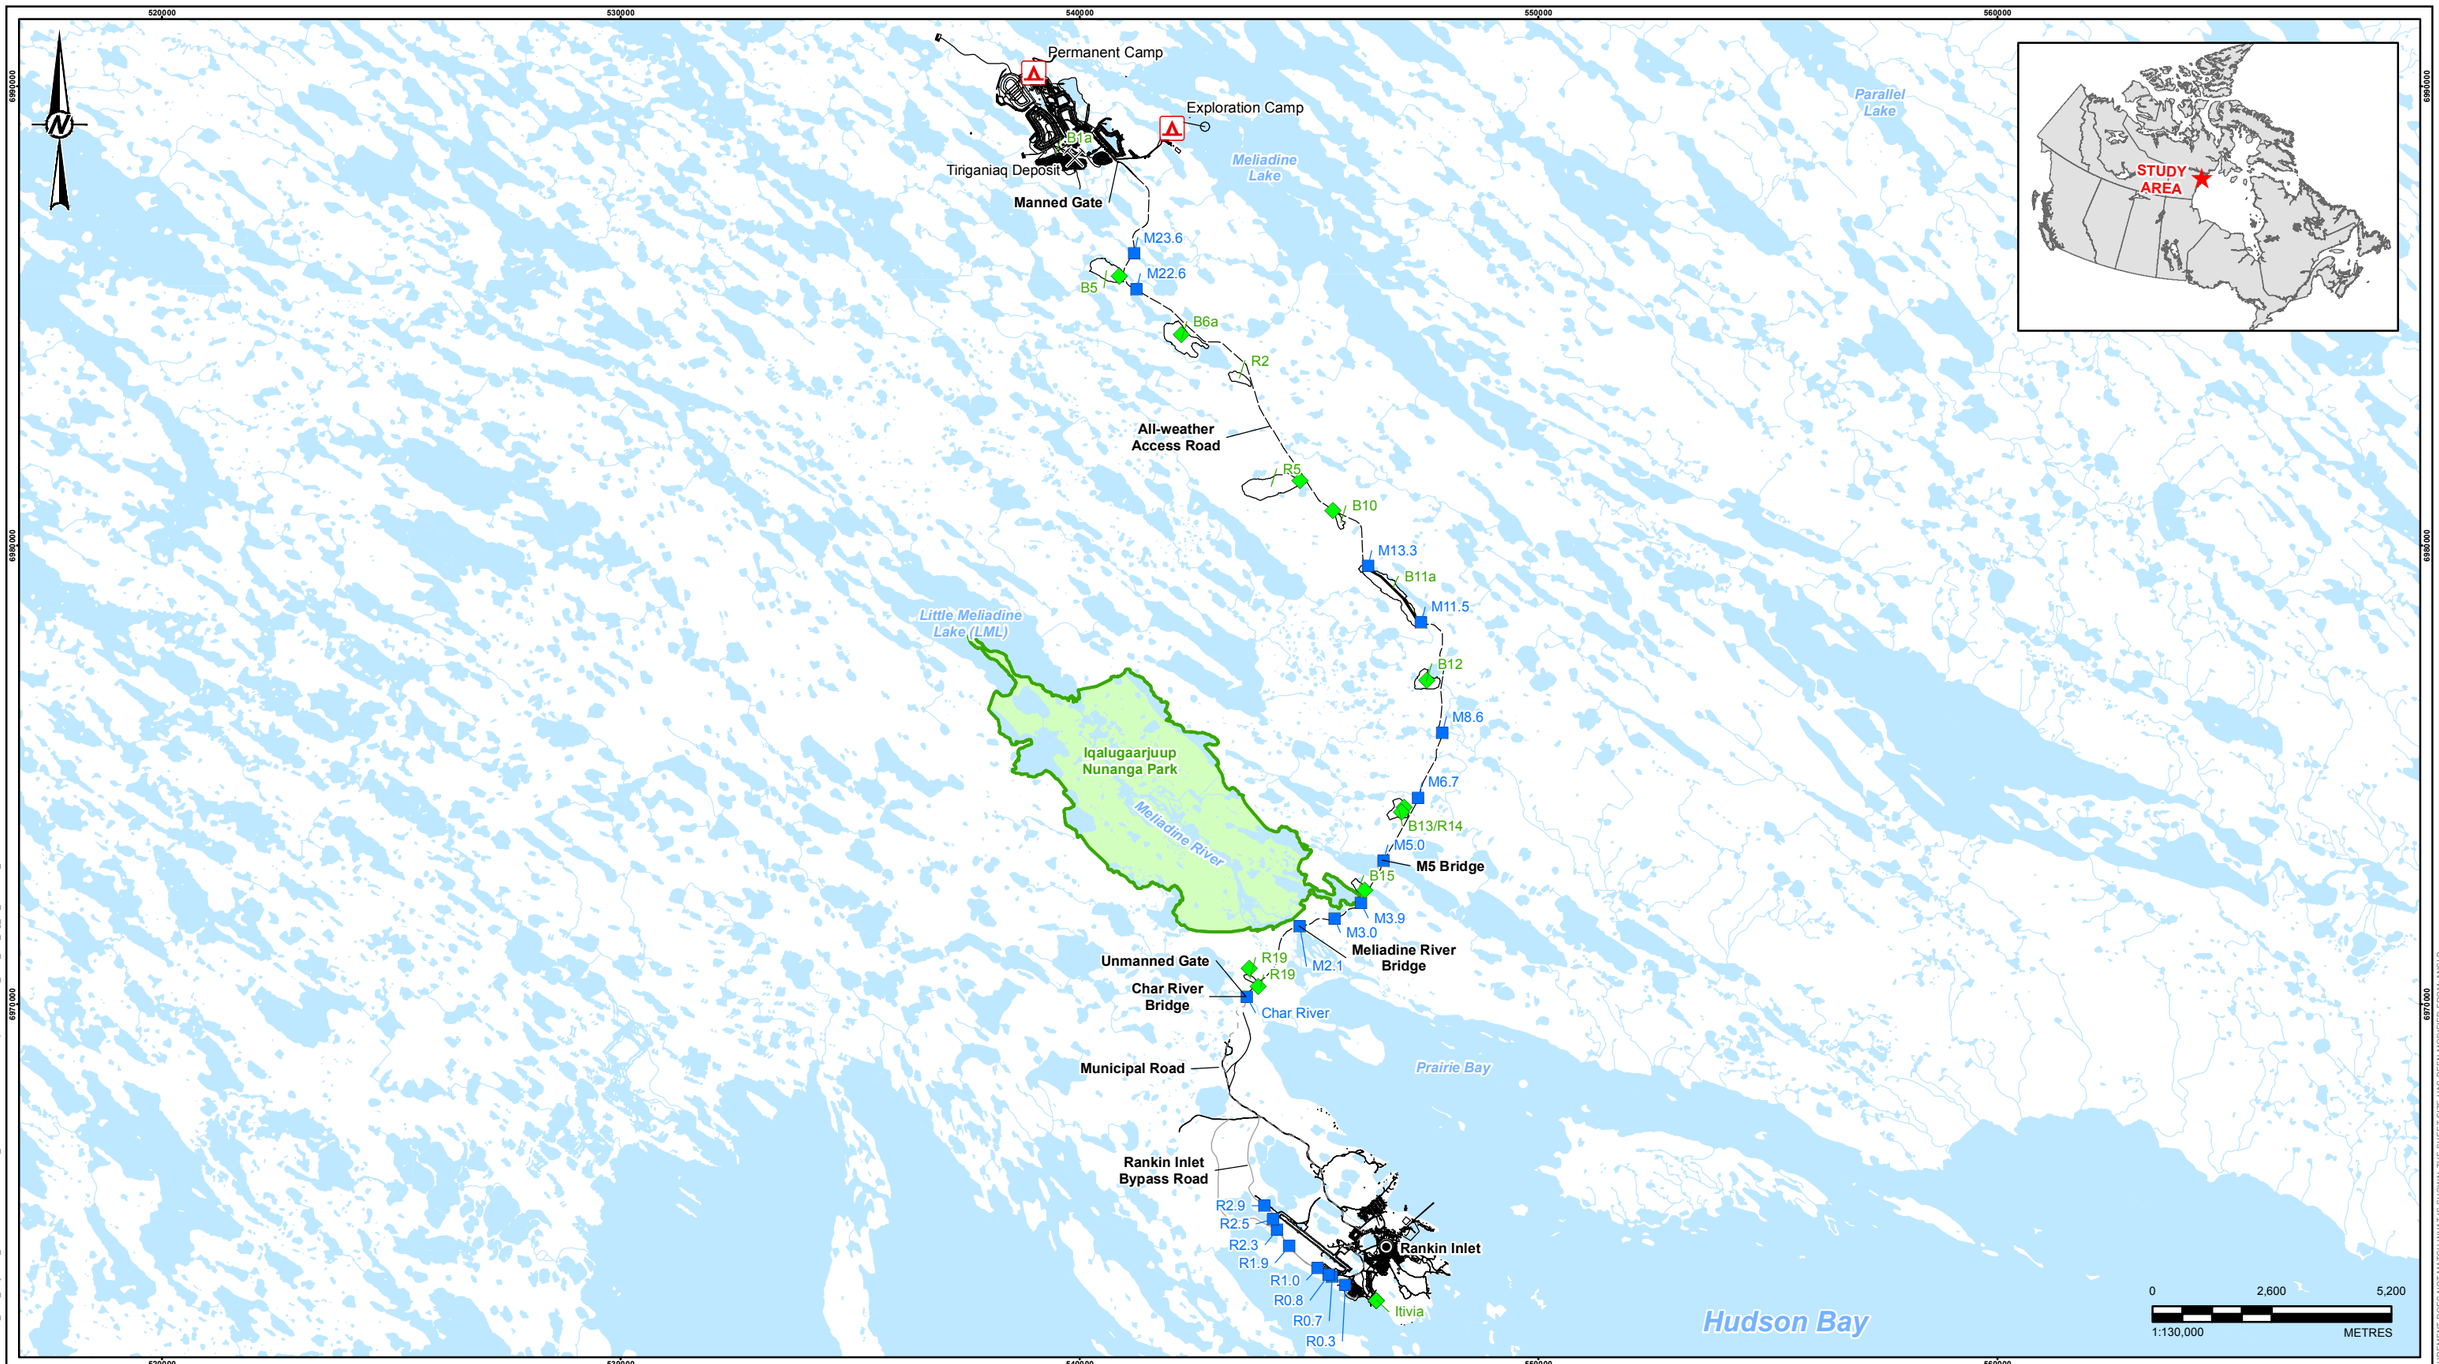
- The south side of the exploration camp pad should be regraded to manage surface water to reduce channelization of the flow that leads to erosion. The slope should also be regraded where erosion has occurred and a coarser surfacing layer could also be placed to help reduce the potential for future erosion.
- The diffuser access road could be regraded to close up the cracks and reduce the potential for future cracking.
- The culverts through the exploration camp access road should be cleared of material.
- The exploration camp access road should be regraded and consideration given to placing some coarser rockfill on the slopes where there is erosion.
- The cracks in fuel storage pad should be monitored; however, they are not considered to be a geotechnical concern.

9.0 ALL-WEATHER ACCESS ROAD (AWAR) AND ASSOCIATED WATER MANAGEMENT STRUCTURES

The All Weather Access Road (AWAR) construction activities began during the winter of 2012, and construction was completed by the end of October 2013 to connect the hamlet of Rankin Inlet to the Project. Appendix B contains photographs taken during the inspection. The road is approximately 23.8 km long, with three bridge crossings and culverts installed at a total of 19 locations. The road has two-way traffic and is approximately 6.5 m wide with pull outs approximately every 400 m ±50 m to facilitate vehicles passing.

The AWAR is used by AEM and also provides unrestricted all-terrain vehicle (ATV) access for the public, if it is safe to do so. The AWAR is used to transport building materials, construction/mining equipment, fuel, reagents, supplies, workers, and contractors to the Project.

The road design is based on a general sub-base composed of rockfill or sand and gravel from esker sources and crushed granular surfacing with a combined minimum thickness of 500 mm. The road design varied based on the relative susceptibility to freeze and thaw induced settlement of the foundation soils. The thickness of the road fill material was generally increased, to a minimum of 1.3 m, in areas where potentially thaw-sensitive soils were identified. Along portions of the road where thaw-sensitive soils were identified, a geotextile material was incorporated into the road design to limit damage to the road should the foundation material thaw.



No evidence of thermal degradation of the permafrost was observed on the road during the inspection. It should be noted that visual evidence may not necessarily be observed due to the regular road maintenance performed by AEM. During the inspection, water levels were considered to be normal to low and flow velocities at the crossings were considered to be low.

9.1 Observations and Recommendations

The culverts were generally observed to be in good condition, at the time of the inspection. Most culverts were unobstructed with no signs of substantial damage to the culverts. All bridges and their embankments were in good geotechnical condition at the time of the inspection. A structural and/or mechanical assessment of the bridges was not conducted and is beyond the scope of this geotechnical inspection.

A photographic record of the inspected culverts and bridges is provided in Appendix B. Figure 5 shows the location of the primary water management structures along the road (e.g., M3.9). However, additional culverts have been added that are not shown in Figure 5.

Table 7 lists the locations of water management structures: culverts and bridges that have been installed along the AWAR. The location of the culverts and bridges are listed, based on distance from the Friendship Centre in Rankin Inlet, with the gate house at Meliadine being 29 km. Size and number of culverts is provided in Table 7, along with specific observations and photos at the time of the inspection, and any recommendations. It was observed during the 2017 inspection that flags with kilometre markings had been installed at the culvert locations; however, the distance markers on the culverts did not match with the location along the AWAR. During the 2018 inspection, AEM indicated that new distance markers had been ordered.

Table 7: 2018 Inspection Record of Water Management Structures along the All-Weather Access Road

Station (distance from Friendship Centre)	Water Management Structure Description	Conditions, Observations, and Recommendations (at time of inspection)
KM 6.0	Char River Bridge	Good condition, stable embankments and abutments. Left abutment downstream, sand and gravel, with potential for erosion. Recommendation: Monitor finer grained material on left abutment to determine if armouring should be added.
KM 6.2	3 CSP culverts: 2 × 1,300 mm 1 × 700 mm	The culverts are vertically offset with the 700 mm culvert elevated above the 1,300 mm culverts. Some minor erosion observed between the culverts on the downstream side. All clear and in good condition. Small flow in the lower 1,300 mm culvert. Recommendation: Monitor to determine if armouring should be added.
KM 7.0	3 CSP culverts: 2 × 1,000 mm 1 × 700 mm	The culverts are vertically offset with the 700 mm culvert elevated above the 1,000 mm culverts. The 700 mm culvert had a dent in side. Ponded water observed in the lower culvert. Small amount of water ponded upstream. Sandy soil around culverts, potential for erosion causing turbidity. Recommendation: Consider adding armouring around culverts to reduce potential for erosion.
KM 7.1	3 CSP culverts: 2 × 1,000 mm 1 × 700 mm	Vertically offset. 700 mm culvert is elevated. Water ponded in the lower culvert on the right side when looking downstream, minor deformation of culverts under the road, no substantial reduction of cross-sectional area. Minor flow in lower 1,000 mm culvert. The culverts and riprap appear in good condition.
KM 7.4	3 CSP culverts: 1 × 900 mm 1 × 700 mm 1 × 1,000 mm	Vertically offset. 700 mm culvert is elevated. Damaged, partially crushed inlet of the 900 mm culvert, but not expected to substantially reduce flow capacity. Erosion potential due to finer grained soils around 700 mm culvert at the inlet and outlet. 1,000 mm clear, low flow/ponding water. Recommendation: Consider extending 700 mm culvert and armour around it to reduce erosion.
KM 8.0	Meliadine River Bridge	Right abutment, downstream slope has exposed esker sand and gravel. Recommendation: Monitor right abutment to determine if armouring should be added.
KM 9.1	2 × 1,000 mm CSP culverts	Minor deformation of both culverts under the road. No flow, water ponded below the inlets. Design was for 5 culverts. No specific mention of capacity issues at this location in AEM inspections.
KM 9.5	1 × 1,300 mm CSP culvert.	Water ponded on upstream side of culvert/road with very low flow due to elevated inlet of CSP. CSP in good condition. Design was for 4 culverts. No specific mention of capacity issues at this location in AEM inspections.
KM 10.5	M-5 Bridge	Good condition, stable embankment and abutments of the bridge. Potential small erosion/settlement of rock embankment on the bridge's right abutment identified during previous annual inspections shows no signs of change. Exposed geotextile at base of downstream end of left abutment that could be due to erosion. Gabion damaged on downstream of Left (north) Abutment. Recommendation: Replace damaged gabion. Continue to monitor for erosion and/or settlement.
KM 12.1	4 CSP culverts: 2 × 1,300 mm 1 × 900 mm 1 × 700 mm	Vertically offset. 700 mm and 900 mm culverts are elevated. Some small dents and bending of haunches in 700 mm and one of the 1,300 mm culverts. Minor flow through the lowest of the 1,300 mm culverts. Embankment slope is generally in good condition.
KM 12.6	no culverts	Area of poor drainage. Flow along west side of road, suspect seepage under the road to east side. Some erosion along toe of road. Recommendation: Monitor this area and if erosion increases or ponding and seepage cause permafrost degradation and settlement of the road fills, a culvert should be installed in this location.
KM 13.5	5 CSP culverts: 3 × 1,300 mm 2 × 900 mm	Vertically offset, 900 mm culverts are elevated above 1,300 mm culverts. Good condition, no flow, minor dents and deflection in haunch.

Station (distance from Friendship Centre)	Water Management Structure Description	Conditions, Observations, and Recommendations (at time of inspection)
KM 14.7	Access road to B12 quarry, 500 mm HDPE corrugated culvert	No flow, small amount of water ponded against AWAR and quarry access road, below inlet of culvert. Minor dents observed in culvert. Small erosion at outlet. Culvert and embankments are generally in good condition.
KM 16.3	3 CSP culverts: 1 × 1,300 mm 1 × 700 mm 1 × 1,000 mm	Vertically offset, 1,300 mm culvert is the lowest, then the 1,000 mm culvert and the 700 mm culvert is the highest. No flow in the 700 mm and 1,000 mm culverts, good condition. Small flow in 1,300 mm culvert, good condition, small erosion visible at outlet. Outlets are all elevated increasing erosion potential. Drainage appears to be connected to M13.3 area (KM18.1 and 18.15), survey required to confirm. Recommendation: Monitor to assess if hydraulic capacity is adequate and if erosion is an issue. Consider installing culverts at lower elevations to improve water management.
KM 18.1	2 CSP culverts: 1 × 900 mm, 1 × 1,000 mm	Vertically offset culverts. The 900 mm culvert is elevated above 1,000 mm culvert. Lower culvert has some flow, minor dent on upstream end. Upper culvert is in good condition. Upper culvert is high on the embankment and has thin cover on the upstream side. Note for flow to occur in upper culvert, the road near KM18.15 would be nearly flooded. Culvert outlet is high, therefore potential for erosion of the embankment during high flow periods exists. Trench exists along upstream toe of road connecting the culverts at KM 18.1 to KM18.15. Recommendation: Monitor cover over upper culvert. If cover thickness is reduced, additional material should be placed to protect the culvert. Consider lowering upper culvert to allow flow with less ponding adjacent to road and less potential for erosion.
KM 18.15	1 × 600 mm CSP culvert.	Ponding on the upstream side. Additional ponding adjacent to road required before reaching the culvert inlet. Culvert outlet elevated, potential for erosion of toe of road embankment. Flow may initially occur through the road fill beneath the culvert. Trench exists along upstream toe of road connecting the culverts at KM 18.1 to KM18.15. Recommendation: Continue to monitor hydraulic capacity. If water management challenges observed, consider installing an additional culvert at this location, at a lower elevation.
KM 19.5	No culverts	Ponding on west side of road, reportedly the water ponds here year-round and can reach as high as half way up the embankment. Inspection reports by AEM note straw logs were placed at KM 19, so there may have been some flow over the road in this area. Recommendation: Consider installation of a culvert at this location.
KM 21.2 to 21.5	No culverts	Water ponded on west side of road near KM 21.2. Water reportedly flowed over the road near KM 21.5 during the 2017 freshet. Straw logs were placed on east side of road embankment to control suspended solids in flow. Recommendation: Install culverts in this area.
KM 21.7	2 × 160 mm steel pipes, used as culverts	Vertically offset steel pipes, clear, no flow. Water ponded upstream, erosion mark from higher water level evident in road embankment. Water reportedly flowed over the road at this location during freshet. AEM personnel report that the road was excavated to allow the water to drain. Capacity of pipes may be inadequate, or pipes could have been frozen (blocked) causing water to backup. Straw logs were observed on west side of road. Recommendation: Consider installation of larger diameter culvert(s). Make sure culverts are clear prior to freshet.
KM 22.3	2 × 160 mm steel pipes, used as culverts	Vertically offset, clear, no flow. Inlets are elevated above ponded water. Recommendation: Consider lowering culverts to reduce ponding upstream.
KM 22.7	No culverts	Water ponded on the east side of the road, signs of wet ground observed on west side of road indicating possible seepage under the road. Recommendation: Consider installing a culvert to manage water in this area.
KM 25.8	1 × 600 mm HDPE corrugated culvert	No flow, minor amount of gravel in base of culvert, some dents on upstream inlet to culvert. Inlet is partially blocked by road fill. Sandy soil around inlet and outlet. Some sediment erosion and deposition evident on downstream side of culvert. Some erosion of slope of road visible in this area. AEM inspection reports noted ponding of water at or over the road in this area during the freshet. Recommendation: Clear culvert inlet of road fill material. Consider adding armouring around culverts. Consider adding additional culverts if water management continues to be an issue during freshet.

Station (distance from Friendship Centre)	Water Management Structure Description	Conditions, Observations, and Recommendations (at time of inspection)
KM 26.2	2 × 160 mm steel pipes, used as culverts	Vertically offset, lower pipe bent upwards, unable to see through, upper pipe is clear. The inlets are elevated close to the road surface. Very thin road fill cover over inlets. Some sediment deposition downstream is evident. Water ponded along road below upstream inverts of pipes. AEM inspection reports noted ponding of water at or over the road in this area during the freshet. Recommendation: Lower pipe should be replaced. Consider adding additional culverts if water management continues to be an issue during freshet.
KM 26.5	3 × 700 mm CSP culverts	Equal elevation, some sediment buildup, no flow, small dents, no blockages.
KM 26.8	2 × 160 mm steel pipes, used as culverts	Vertically offset, no flow. Inlet of the lower culvert was completely covered by new road fill. Some erosion evident at downstream ends. Recommendation: Inlet of the lower culvert should be cleared and extended or culvert should be replaced.
KM 27.1	3 CSP culverts: 1 × 900 mm 1 × 700 mm 1 × 1,000 mm (southernmost)	Vertically offset, middle culvert (700 mm) elevated above adjacent culverts. Clear, minor flow in lowest culvert, some small dents in 900 mm and 1,000 mm culverts. Some sloughing of riprap near culvert inlets. Recommendation: Monitor riprap and add more protection if more erosion occurs.
KM 28.7	No culverts	Ponded water on east side of road. AEM notes that water ponds against road for most of open water season and road surface is often soft, indicating signs of seepage through road. This year water flowed over the road at this location during freshet. Recommendation: Install a culvert at this location.
KM 29.6	1 × 500 mm HDPE corrugated culvert	No flow, some small dents, small erosion evident upstream, water ponded upstream. Inlet is partially blocked by road fill and riprap. Recommendation: Clear the culvert inlet and consider lowering culvert to reduce ponding adjacent to road.

1 ×__ mm = the number of culverts × the diameter of the culvert.

CSP = corrugated steel pipe; AWAR = all-weather access road.

AEM has implemented a watercourse crossing inspection and maintenance program (AEM 2015b), which includes:

- a regular inspection program to identify issues relating to watercourse crossings, such as structural integrity and hydraulic function
- an event-based inspection program to track the impacts of larger storm events on watercourse crossings
- a culvert location inspection program to ensure that culverts have been installed in the correct location with respect to watercourses and that the culvert capacity is adequate, for hydraulic conditions

A total of 20 inspections were conducted and documented by AEM's environment and site services departments in 2018. Inspections were carried out more frequently during freshet (May and June). There was no record of inspections carried out in February, July, August, September or December. AEM indicated that the site services department conducts weekly inspections, but reporting is not always completed.

Prior to spring freshet, the culverts and bridges were inspected to assess their condition and ability to accommodate rapid spring thaws. The visual inspections are intended to identify any structural issues, blockages, ponding against or over the road, required maintenance, damage, bed erosion, or scour. The inspections include photos of key observations and are documented and filed for future reference.

Road maintenance and snow management are carried out, as deemed necessary. Steaming of culverts, is included as a maintenance activity. AEM indicated that they re-capped the AWAR and applied calcium spray for dust control through the spring and summer. Six new pull outs were also added along the AWAR in 2018.

Records of the inspections carried out by the environmental and site services teams were provided to Golder for review. The following are some of the key observations related to geotechnical stability that were documented in the inspection reports:

- Road was typically noted to be in good condition from January to March.
- Snow clearing was noted to have been pushed properly so as not to disturb the tundra.
- 4 May 2018 – Started clearing Char River crossing. Meliadine River and M5 water crossing along with culverts to be cleared.
- 9, 17, and 27 May 2018 – Culverts North of KM 8.6 need to be cleared. All bridges along the AWAR are clear. Culverts south of KM 8.6 are cleared.
- 1 June 2018 – Most of the culverts along the AWAR are snow covered and should be cleared by 6 June 2018. High temperatures are expected following 6 June 2018 and culverts should be clear to prevent erosion of road.
- 6 June 2018 – Flow across the AWAR at KM 24 is beginning to wash out the road. Straw logs are being installed at downstream side of road to control sediments. KM 28 has developed a pond adjacent to the road that has begun to flow and poses wash-out hazards. Straw logs are being placed.
- 9 June 2018 – Straw log set-ups were installed along the AWAR at KM 22 and KM 19. The AWAR will continue to be inspected, and problematic water crossings reported/addressed.
- 10 to 13 June 2018 – Culverts currently being cleared to prevent flow across road. Straw logs have been installed where flow across road is ongoing at locations not containing culverts where no culverts exist.
- 14 June, 13 and 20 October, 12 November 2018 – No issues.

10.0 ITIVIA FUEL STORAGE SITE AND BYPASS ROAD

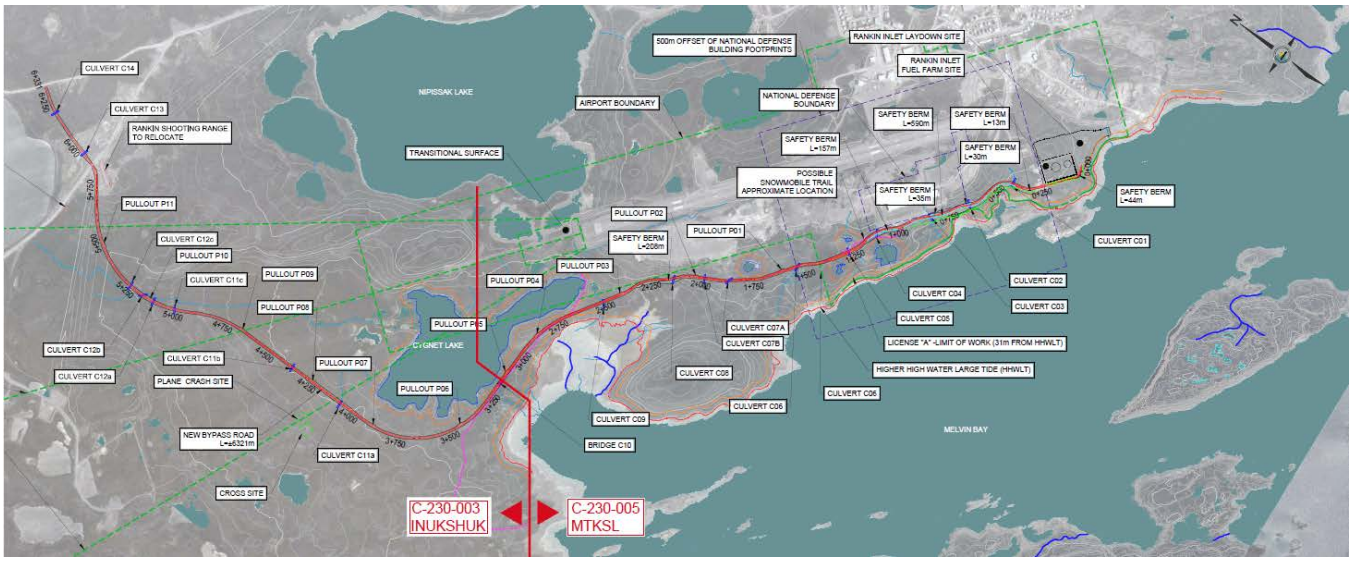
The Itivia site is located south of Rankin Inlet on the north shore of Melvin Bay (Figure 6). It is used for bulk fuel storage and provides a laydown area for transfer of materials to the Meliadine Mine. To minimize impacts on Rankin Inlet, AEM constructed a bypass road to divert traffic travelling to and from the Itivia site and the Project site around Rankin Inlet. The following sections provide a summary of the observations and recommendations relating to the fuel storage site bypass road. The Itivia site and bypass road were constructed in 2017 and 2018.

10.1 Visual Observations

10.1.1 Fuel Storage and Laydown Area

The inspection involved walking along the crests and toes of the containment berms and examining the condition of the pad slopes for visual signs of deformation and instability, cracking, uneven surfaces or seepage. A selection of the photos taken during the site visit are provided in Appendix D (Photographs 1 through 11).

The laydown pad areas had been constructed with rockfill and crushed aggregate materials and the slopes appeared to range from about 2 to 3 horizontal to 1 vertical (Photographs 3 through 6, Appendix D). There is a rock cut face between the fuel storage facility and the upper laydown area above at the northwest corner of the fuel storage facility (Photograph 7 and 8, Appendix D). There were no geotechnical concerns identified.



The fuel storage area has two tanks (20 million and 13.5 million litres) within a bermed secondary containment facility. The raised base and perimeter berms of the secondary containment were constructed out of rockfill with liner bedding and transition layers and an HDPE liner.

The perimeter berms for the secondary fuel containment were generally in good condition. The liner was exposed due to minor sloughing of the liner cover material in a few locations on the south containment berm (Photographs 9 and 10, Appendix D). There was a shallow pond of water over the base of the containment facility south of the tanks (Photograph 11, Appendix D). A pumper truck was working on removing this water, taking it back to the Project site for treatment, at the time of the site visit. The pad areas for the laydown were constructed with rockfill and crushed materials and the slopes were in good condition, no signs of erosion, cracking or instability.

Two 900 mm corrugated steel culverts are installed across the access road into the Itivia site (Photographs 1 and 2, Appendix D). Some damage was observed on the outlet ends of the culverts. There was some water ponding on the upstream side of the culverts and a small flow through the lower culvert. Crush material had been placed at the outlets of the culverts with straw logs and rip rap placed in a semi-circle around the outlets for water management. There were no geotechnical concerns identified.

10.1.2 Bypass Road

The Itivia bypass road is a 6.3 km gravel road that was constructed to divert traffic from the Itivia fuel storage and laydown area to the Project site around Rankin Inlet (Figure 6). The road is designed to be 6.5 m wide for most of its length with pull outs to allow two-way traffic. Two sections are designed to be 8 m to allow two-way traffic without pullouts. A total of 19 culvert crossings were constructed along the length of the road. The road was constructed in 2017 and 2018 and was completed during the week of the 2018 inspection. The eastern portion of the road was constructed using blast rock from the Itivia Quarry, but the majority of the road was constructed using esker materials.

Source: Tetra Tech 2017e.
Figure 6: Itivia Bypass Road Alignment

The inspection of the Itivia Bypass Road was completed 14 September 2018 beginning at the Rankin Inlet Fuel Farm and advancing up station along the road alignment to the intersection with the AWAR. The inspection involved driving along the road and examining the condition of each of the culverts as well as examining the road surface and slopes for visual signs of erosion, deformation, instability, or cracking. Observations of ponded water were also noted. At the time of the inspection construction was generally complete. Construction activities observed during the inspection were limited to compaction of the road surfacing materials with a smooth drum vibratory roller.

The southeast corner of the Itivia fuel storage facility was marked as kilometre 0 and approximate culvert locations along the road were measured using the truck odometer. Some culvert locations measured during the inspection do not correlate with the design stationing in the construction drawings. At the time of compiling this inspection report, an as-built report was being prepared by AEM and had not yet been issued for the Itivia Bypass Road. Some of the culvert locations may have been adjusted during construction and AEM indicated that Culvert 08 was not installed based on topography in the area where it was planned. All culverts were inspected and generally appear to have been installed per the configurations detailed in the design report documents (Tetra Tech 2017a, d and e). Time was limited to complete the inspection, so dimensions of the culverts could not be confirmed in the field and are reported based on the design report documentation.

The as-built report should confirm culvert sizes and locations, confirm that safety berms have been constructed where required based on road fill height, and confirm that road slopes have been constructed to the design.

In general, the road was in very good condition as construction had just been completed. There were no signs of cracking or settlement. The majority of the road was constructed using esker materials which may be susceptible to erosion and some sections of the road appeared to have relatively steep embankment slopes in consideration of the materials used for construction. Some sections of the road were high enough that they required safety berms, which were constructed using large boulders along the eastern section and with esker materials along the remainder of the road. As per the design layout, the lower culverts were installed below grade. Riprap was placed at the inlet and outlets of culverts, per the design, with the exception of C7b, which is missing riprap at the outlet. AEM indicated that placement of this riprap is planned for 2019. The culverts should be monitored for potential erosion of rip rap materials placed upstream into the culverts.

Table 8 presents a summary of the culvert inspections completed.

Table 8: Itivia Bypass Road Culvert Inspection Summary

Approximate Distance from SE corner of Fuel Farm [(a)]	Culvert Design Identification	Water Management Structure Description	Observations	Photographs (Appendix D2)
0.35 km	C01	2 x 1,000 CSP culverts	Design configuration A. No water flowing through culverts. Potential for erosion of riprap placed upstream into the lower culvert. Road constructed out of blast rock. Large boulders placed on south crest of road as safety berm. Recommendation: Monitor for erosion of riprap into lower culvert.	12
0.6 km	C02	2 x 700 mm CSP culverts	Design configuration A. No water flowing through culverts. Some large boulders partially blocking the outlet of the lower culvert. Some larger rocks above the culverts that may be locally over steepened and have the potential to fall and damage or block the culverts. Road constructed out of blast rock. Large boulders placed on south crest of road as safety berm. Recommendation: Remove riprap that is partially blocking lower culvert.	13
0.8 km	C03	2 x 1,000 mm 1 x 700 mm	Design configuration B. No water flowing through culverts. Channel erosion in tundra observed upstream of culverts. Road constructed out of blast rock. Large boulders placed on south crest of road as safety berm. Recommendation: Monitor erosion channel upstream of culverts. Not expected to be an issue, but if erosion continues, consider armouring the channel.	14 to 16
1.0 km	C04	2 x 1,000 mm	Design configuration A. Some cobbles observed in front of the lower culvert inlet that may erode into the culvert. Road constructed out of blast rock. Large boulders placed on south crest of road as safety berm. Recommendation: Remove riprap that is in front of the lower culvert.	17 and 18
1.2 km	C05	2 x 1,000 mm	Design configuration D. No water flowing through culverts, inlets and outlets armoured with smaller material than culverts C01 to C04. Some rockfill in front of inlets could erode into the culverts. Road and safety berm on south crest of road constructed out of esker materials. Recommendation: Remove riprap from in front of culvert inverts. Monitor erosion of safety berm.	19 and 20
1.5 km	C06	2 x 800 mm	Design configuration D. Culvert inlets installed above surrounding natural ground. Ponded water against toe of road north of the culvert inlets, a small berm has been constructed between the ponded water and the culvert inlet location. No water flowing through the culverts. Some rockfill in front of inlets could erode into the culverts. Road constructed out of esker materials. Recommendations: Remove riprap from in front of culvert invert. Monitor ponding of water, consider ditching to drain water to culvert inlets or add additional culvert where water is ponding.	21 to 23
1.6 km	C06-1	1 x 800 mm	AEM indicated this was an additional culvert installed based on the conditions observed in the field. Road constructed out of esker materials.	24 and 25
1.8 km	C07a	2 x 800 mm	Design configuration D. Ponded water observed at the inlets around the culverts and against the toe of the road embankment. Small flow through the east culvert. Culvert inlets installed over rockfill base raised above surrounding natural ground. Road constructed out of esker materials. Recommendation: Monitor ponding of water upstream of inlets and consider lowering culverts to reduce ponding.	26 and 27
1.9 km	C07b	2 x 1,000 mm	Design configuration D. No water flowing through the culverts, inlets and outlets are clear. Road constructed out of esker materials. Safety berm constructed on south crest of road. No armouring placed at outlet. Recommendation: Monitor potential erosion of safety berm. Place riprap to armour outlet.	28 and 29
2.4 km	C09	2 x 1,000 mm	Construction drawings identify C09 to be design configuration A. Culverts observed at this location are in design configuration D. No water flowing through culverts. Ponded water observed around the inlets and against the toe of the road embankment to the south. Road constructed out of esker material. Recommendation: Monitor ponding upstream of inlets and consider adding or relocating culvert(s) to reduce ponding.	30 and 31
3.1 km	C10	5 x 1,200 mm 1 x 1,000	Design configuration per Tetra Tech 2017d. Some damage to culvert inlets and deformation under road observed. Some water flow observed flowing into embedded culvert. Ponded water observed along the toe of the road embankment to the north of the culvert inlets. Road constructed out of esker material. Recommendation: Repair damaged culvert inlets and remove riprap that is partially blocking inlets.	32 to 34

Approximate Distance from SE corner of Fuel Farm [(a)]	Culvert Design Identification	Water Management Structure Description	Observations	Photographs (Appendix D2)
4.0 km	C11a	2 x 1,200 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. Some flow observed through both culverts. Shallow ponding of water over tundra upstream of the inlets and against the toe of the road embankment. Water mark visible along toe of road embankment. Road constructed out of esker material. Recommendation: Monitor ponding upstream of inlets and adjacent to road to determine if water should be ditched to inlets of culverts or if additional culverts required.	35 and 36
4.3 km	C11b	2 x 1,000 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. Some flow through the north culvert. Water ponded over tundra on both sides of culverts. Shallow ponded water at about KM 4.6 with channel running along toe of road embankment back to culvert C11b. Road constructed out of esker material. Recommendation: Monitor water ponding near KM 4.6 and flow along toe of road to determine if additional culvert required.	37 and 38
4.8 km	C11b-1	1 x 1,000 mm	AEM indicated this was an additional culvert installed based on the conditions observed in the field. Culvert is constructed over riprap and invert is raised above surrounding tundra. Small natural drainage path observed upstream and downstream of culvert. Water observed within drainage downstream of outlets. Small amount of water ponded in culvert, but no flow. Shallow ponded water at the toe of the road embankment to the south of the culvert. Road constructed out of esker material.	39 and 40
4.9 km	C11c	2 x 1,200 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. No flow through culverts. Shallow ponded water observed upstream and downstream of the culverts. Road constructed out of esker materials.	41 and 42
5.0 km	C12a	2 x 1,200 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. Ponded water observed over tundra upstream and downstream of the culverts. No flow through culverts. Road embankment looks steeper on east side compared to west side. Road constructed out of esker materials. Recommendation: Confirm road embankment slopes from as-built survey.	43 and 44
5.1 km	C12b	2 x 1,000 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. Water ponded upstream and downstream of the culverts and along the toe of the embankment. Road constructed out of esker materials. Recommendation: Monitor ponding upstream of culverts and adjacent to road and the condition of the road to determine if mitigation is required. Ditching or placement of fill material along the toe of the road to promote flow to the inlets of culverts, culverts could be lowered, or additional culverts could be added.	45 and 46
6.2 km	C13	2 x 800 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. Relatively large pond of water upstream and downstream of the culverts; road constructed through natural pond. Road constructed out of esker materials. Recommendation: Monitor ponding upstream and downstream of culverts and road condition to determine if mitigation required. Culverts could be lowered and/or material could be placed along toe of road to keep water away from road foundation.	47 and 48
6.3 km	C14	3 x 800 mm	Design configuration D. Culverts are constructed over riprap and inverts are raised above surrounding tundra. Water ponded upstream and downstream of the culverts. Road constructed out of esker materials. Recommendation: Monitor ponding upstream and downstream of culverts and road condition to determine if mitigation required. Culverts could be lowered and/or material could be placed along toe of road to keep water away from road foundation.	49 and 50

Notes: Dimensions, names, and alignment stations presented in the table are taken from the Tetra Tech design report and associated construction drawings, including amendments (Tetra Tech 2017a, d, and e).

1 ×__ mm = the number of culverts × the diameter of the culvert.

(a) Distances measured with truck odometer.

CSP = corrugated steel pipe; AWAR = all-weather access road.

10.2 Recommendations

The following are recommendations for the Itivia fuel storage area and by-pass road:

- The damaged outlets of the culverts through the entrance to the Itivia fuel storage area should be fixed.
- Cover material should be re-established over the liner that has been exposed on the south containment berm of the Itivia fuel storage facility to protect the liner.
- The locations and layouts of some of the culverts through the Itivia by-pass road do not correlate with the design drawings (Tetra Tech 2017e) and Figure 6. The discrepancy is due to modifications to the locations and layouts during construction based on site observations and conditions. The culvert locations should be referenced to the as-built report and drawings during the 2019 annual geotechnical inspection.
- The as-built report should confirm culvert sizes, locations, and invert elevations have been constructed to the design. The as-built report should also confirm that safety berms have been constructed where required based on road fill height and confirm that road slopes have been constructed to the design.
- The section of the road that is constructed with esker material may be susceptible to erosion. This should be monitored and maintenance completed as required. Coarser material can be placed for erosion protection if erosion occurs in some areas.

11.0 SUMMARY AND RECOMMENDATIONS

The results of the 2018 annual geotechnical inspection carried out at the Project site, along the AWAR, at the Itivia site, and along the Itivia by-pass road indicate that the infrastructure was generally in good condition and performing as designed.

The following presents a summary of the recommendations from the 2018 geotechnical inspection for the infrastructure in each of the areas inspected. The recommendations have been grouped based on the type of recommendation and have also been given a rating of High (L), Medium (M), or Low (L) priority.

The following recommendations are related to surveillance and monitoring:

The recommendations for surveillance and monitoring don't currently require a maintenance action but may warrant future maintenance if conditions worsen.

Main Site

- Geotechnical inspections should be carried out and documented for D-CP1 and D-CP5 following the schedule developed in the OMS manual. In addition, instrumentation should be monitored, and the data should be plotted and reviewed, following the schedule developed in the OMS manual. These activities were completed by AEM in 2018; however, not quite to the schedule in the OMS. The OMS manual indicates that daily inspections should be completed and documented using the same form as the weekly inspection, which were not completed in 2018. The OMS manual does not indicate if there is seasonal variability to the frequency of documented inspections. It may be acceptable to seasonally vary the frequency of inspections, but this should be reviewed with the Engineer of Record (EoR) for the dikes and the OMS manual should be updated, as required. The OMS manual should be reviewed and updated annually and is next due for review in June 2019. (H)
- If the P-Area dikes will continue to be used, they should be added to the OMS manual that was developed for D-CP1 and D-CP5. Geotechnical inspections and instrumentation monitoring should be carried out and documented following the schedule developed in the OMS manual. (H)
- Implement a road and culvert monitoring program for site roads, as is done for the AWAR, which is tied to a maintenance program. (M)
- Conduct inspections along Itivia by-pass road, as per the Road Management Plan (AEM 2015b), now that the road is complete. (M)
- Monitor the cracking adjacent to Channel 5. If cracking gets worse, recontouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks leading to warming of the permafrost and additional thaw settlement and cracking. (M)
- Monitor the cracking observed in the D-CP1 downstream sump berms and adjacent to the downstream collection channel. Recontouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks leading to warming of the permafrost and additional thaw settlement and cracking. (M)

- Ponding upstream of Berm 3 should be monitored to determine how much and how often ponding occurs and if Berm 3 can perform as required with the ponding. (M)
- The Berm 3 cover materials may be susceptible to erosion. This should be monitored, and if there is erosion, consideration should be given to placing coarser material on Berm 3 to reduce the potential for erosion. (M)

Exploration Site

- The cracks in fuel storage pad should be monitored; however, they are not considered to be a geotechnical concern. (L)

All-weather Access Road

- Continue to monitor culverts and hydraulic effectiveness to assess if current culverts provide adequate capacity and if any changes are required. Evaluate if any culverts need to be installed at a lower elevation to reduce ponding, and downstream erosion. (M)
- Monitor areas that have ponding, but no culverts and consider installing culverts to manage water. (M)
- Conduct inspections and document observations and recommendations as laid out in the Road Management Plan (AEM 2015b). Road inspections were completed and documented in 2018, but documentation indicates that the frequency of the inspections did not quite meet what is laid out in the Road Management Plan. (H)

Itivia Site and By-pass Road

- The locations of some of the culverts through the Itivia by-pass road do not correlate with the design drawings (Tetra Tech 2017e) due to changes made during construction. The culvert locations should be referenced to the as-built report and drawings during the 2019 annual geotechnical inspection. (M)
- The as-built report should confirm culvert sizes, locations, and invert elevations have been constructed to the design. The as-built report should also confirm that safety berms have been constructed where required based on road fill height and confirm that road slopes have been constructed to the design. (M)
- The section of the road and safety berm that is constructed with esker material may be susceptible to erosion. This should be monitored and maintenance completed as required. (L)
- Ponding of water along the road should be monitored and if it is impacting the condition of the road, mitigation measures should be implemented, such as, lowering the culverts or ditching or placing fill to direct water to the culvert inlets. (M)

The following recommendations are related to operational procedures:

Main Site

- Water volumes within containment ponds should be managed to the levels defined in the OMS manual, including maintaining the water level below the elevation defined for the end of October in the OMS manual over the winter to promote freezing of the dikes. (H)
- The D-CP1 sump and downstream collection channel should be emptied in the fall/early winter to refreeze the ground around these facilities. During the open water season, keeping the water level in the downstream channel and sump low will reduce the potential for thaw of the ground around the channel and sump and associated settlement. (M)
- Consider adding data loggers to thermistors for easier collection of data, especially in the winter when access may be more limited. (L)
- Where possible, try not to allow seepage water from DP3-A to pond against the Saline Pond berm to avoid permafrost degradation. (M)
- Monitor slopes above Portal No. 2 for rockfill instability during backfill placement. (H)
- Snow management around Portal No. 1 and 2 may be advisable prior to freshet to reduce inflows to the underground. (L)

Exploration Site

- Minimize the amount of water contained within the exploration landfarm until it is decommissioned and remediated. (M)

The following recommendations relate to maintenance or repairs that are required:

Main Site

- Cracks and areas of settlement in the containment pond dikes should be filled and/or recontoured to close the cracks and reduce the potential for infiltration and erosion. (M)
- Ponding of water adjacent to roads should be avoided. Disturbed areas from road construction should be recontoured to promote drainage away from the road and consideration should be given to installing culverts if ponding occurs in naturally low areas. This was most notable along the Emulsion Plant and Wesmeg Borrow access roads. (M)
- If the Wesmeg Borrow access road is blocking drainage near Lake B33A that is leading to ponding adjacent to the road, a culvert should be installed to allow drainage so that there isn’t permafrost degradation and settlement. (M)
- Consider adding a crushed surface material to the Emulsion Plant and storage area pads if trafficability continues to be an issue. (M)
- Survey monitoring plate M-3 on D-CP5 should be replaced. (M)

- Where erosion is occurring on slopes of pads, the existing materials should be regraded and compacted, and a coarser material should be placed to further reduce erosion potential. Higher priority should be given to areas where erosion is encroaching on sea containers or other facilities placed close to the slope. The most significant pad erosion was observed at the north side of the main camp/industrial pad and the Emulsion Plant pad. (M)
- The cracking and sloughing along Channel 1 should be assessed to determine if the channel is too steep and riprap is sloughing over geotextile or if it is caused by thermal degradation of permafrost adjacent to the channel. If possible, the channel should be kept empty through the winter to promote freezing of the permafrost around the channel. (M)
- Where access is feasible, removal of snow from the water collection pond dikes (temporary and permanent) is recommended to reduce the insulating effects of the snow, thereby allowing the temperature of the core material in the dikes and the foundations to drop as low as possible. Snow removal is more important if thermistor data is indicating that the dike and/or foundation temperatures are warmer than expected. (M)
- Make sure thermistors in the water management dikes are well marked so they can be located and maintained during the winter and are not damaged during snow removal operations. (H)
- The slopes of the Operation Landfill should be monitored, particularly the northeast corner where water was observed to be ponding downstream and there was some possible sloughing on the slope. Regrading and compacting the slope in this area will reduce the potential for erosion. (M)
- Consider adding rockfill material to cover the till berm in P1, to protect the till and maintain its integrity if this berm is required for water management. (L)
- The Wesmeg Borrow Area should be recontoured and either capped with a coarser material or revegetated to reduce erosion. (M)
- A coarser rockfill layer should be placed over the decommissioned exploration landfill to reduce erosion and cracking. (M)
- Snow management around and above Portal No. 1 and 2 may be advisable, especially prior to freshet, to reduce the potential for larger surface water inflows entering the underground. (L)

Exploration Camp Site

- Repair surface erosion along south slope of exploration camp pad. Grade surface to reduce channelization of surface water flows and therefore reduce the potential for the erosion to reoccur. In this area, a coarser surfacing layer could be placed to help reduce the potential for future erosion. (L)
- The exploration camp access road should be regraded and consideration given to placing some coarser rockfill on the slopes where there is erosion. (M)
- The culverts through the exploration camp access road should be cleared of material. Large boulders should be removed from above culverts to prevent potential damage to the culverts and appropriately sized riprap should be added to the road fills around he culverts for erosion protection where there isn't any. (M)

- The diffuser access road could be regraded to close up the cracks and reduce the potential for future cracking. (L)

All-weather Access Road

- The kilometre markings on the AWAR culverts should be checked and replaced with accurate numbers. At the time of the 2018 site visit, AEM indicated that new markers had been ordered, but had not arrived. (M)
- Specific recommendations for the AWAR culverts and bridges are summarized in Table 9.

Itivia Site and By-pass Road

- Cover material should be re-established over the liner that has been exposed on the south containment berm of the Itivia fuel storage facility to protect the liner. (M)
- The culverts should be cleared of all materials prior to freshet. (H)

The following recommendations relate to future construction:

- Road and pad materials should be compacted to reduce the potential of the material being eroded, and if necessary a coarser, well graded, cover material should be placed to further reduce erosion potential.
- When culverts are installed, ensure bedding material surrounding culverts is of a suitable gradation (e.g., sandy) and compacted. Large boulders should not be placed in direct contact with the culverts within the road fills; however, the slopes of the road around the outlets of the culverts should be armoured with appropriately sized material (e.g., cobbles) to reduce erosion.

Table 9: Recommendations for All-Weather Access Road

Station (distance from Friendship Centre in Rankin Inlet)	Water Management Structure Description	Recommendations
KM 6.0	Char River Bridge	Monitor for potential erosion of sand and gravel on left abutment downstream to determine if armouring should be added. No substantial erosion noted to date.
KM 6.2	3 CSP cuverts: 2 × 1,300 mm 1 × 700 mm	Monitor erosion between culverts to determine if armouring should be added.
KM 7.0	3 CSP culverts: 2 × 1000 mm 1 × 700 mm	Potential for erosion of sandy soil around culverts. Monitor to determine if armouring should be added.
KM 7.4	3 CSP culverts: 1 × 900 mm 1 × 700 mm 1 × 1000 mm	Erosion potential due to sandy soils around 700 mm culvert. Consider extending and adding armouring.
KM 8.0	Meliadine River Bridge	Right abutment, downstream slope has exposed esker sand and gravel. Monitor to determine if armouring should be added.
KM 10.5	M-5 Bridge	Potential small erosion/settlement of rock embankment on the bridge's right abutment identified during 2016 inspection shows no signs of change. Continue to monitor. Exposed geotextile at base of downstream end of left abutment that could be due to erosion, so should be monitored.
KM 12.6	no culverts	Area of poor drainage. Flow along road edge, suspect seepage under the road. Some erosion along toe of road. Monitor and consider installing a culvert to manage water and/or rockfill to protect road.
KM 16.3	3 CSP culverts: 1 × 1,300 mm 1 × 700 mm 1 × 1,000 mm	Outlets are all elevated increasing erosion potential. Monitor to assess if hydraulic capacity is adequate and if erosion is an issue. Consider installing culverts at lower elevations to improve water management.
KM 18.1	2 CSP culverts: 1 × 900 mm, 1 × 1,000 mm	Consider adding cover over upper culvert on upstream side. Upper culvert outlet is high, therefore water has to pond close to road surface for culvert to pass flows. Elevation of culvert leads to potential for erosion during high flow periods. Assess if hydraulic capacity is adequate.
KM 18.15	1 × 600 mm CSP culvert	Invert and outlet are both elevated, increasing erosion potential. Some erosion of road slope and toe visible. Assess if hydraulic capacity is adequate. If water management challenges observed, consider installing an additional culvert at this location, at a lower elevation.
KM 19.5 (approx.)	No culverts	Ponding on west side of road and AEM reports water flowing over the road at KM 19. Consider installation of a culvert at this area.
KM 21.5	No culverts	AEM reported that water flowed over road at this location during freshet. Consider adding a culvert to manage water.
KM 21.7	2 × 160 mm steel pipes, used as culverts	High water level evident near road surface. AEM indicate road was excavated to release flow. Consider marking pipe location and cleaning out, prior to freshet. Monitor for signs of erosion and adequacy of hydraulic capacity. Add additional culvert in this area if required.
KM 22.7	No culverts	Water ponded on the east side of the road, signs of wet ground observed on west side of road indicating possible seepage under the road. Consider installing a culvert.
KM 25.8	1 × 600 mm HDPE corrugated culvert	Culvert is partially blocked by road fill. Sandy soil around inlet and outlet and some sediment erosion. AEM inspection reports noted ponding of water at or over the road in this area during the freshet. Clean out culvert. Consider adding additional culverts if water management continues to be an issue during freshet. Also consider adding armour around culvert and on road slopes.
KM 26.2	2 × 160 mm steel pipes, used as culverts	Lower pipe bent upwards and should be replaced. Some sediment deposition downstream is evident. Water ponded along road below upstream inverts of pipes. AEM inspection reports noted ponding of water at or over the road in this area during the freshet. Lower pipe should be replaced. Consider adding additional or larger culverts if water management continues to be an issue during freshet.
KM 26.8	3 × 700 mm CSP culverts	Clear inlet of lower culvert of road fill material and extend.
KM 28.7	Seepage	Ponded water on east side of road. AEM notes that water ponds against road for most of open water season and road surface often is moist, indicating signs of seepage through road. Consider installation of a culvert.
KM 29.6	1 × 500 mm HDPE corrugated culvert	Clear culvert of road fil material.

1 ×__ mm = the number of culverts × the diameter of the culvert.

CSP = corrugated steel pipe.

12.0 CLOSURE

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

This report was prepared to summarize the findings of the 2018 geotechnical inspection conducted between 10 and 14 September 2018, to comply with the requirements of AEM's Type A Water Licence No. 2AM-MEL1631, Part I, Item 14 (page 21) and Schedule I, Item 1 (page 39).

We trust the information provided within is sufficient for your current needs. Should you require additional information or further clarification, please contact us.

Photograph 3: DP1-A, North Slope Looking Southwest, Minor Slumping that was not observed during 2017 inspection (12 September 2018)

Photograph 4: DP1-A, Cracking Observed on Crest, Similar Condition to 2017 (12 September 2018)

Photograph 5: DP1-A, South Slope, Looking Southwest (12 September 2018)

Photograph 6: Pond 1 from DP1-B, Looking Southeast (12 September 2018)

Photograph 7: Snow Melt Management Pond, Looking South (12 September 2018)

Photograph 8: Snow Melt Management Pond, East Berm Downstream Slope, Looking North (12 September 2018)

Photograph 9: Snow Melt Management Pond, South Berm, Looking West (12 September 2018)

Photograph 10: DP1-B, Upstream Slope from Jetty 2 Looking East toward Snow Melt Management Pond, Minor Erosion on Slope (12 September 2018)

Photograph 11: DP1-B, Downstream Slope, Looking East. Orange Delineator on Crest Marks Thermistor Location (12 September 2018)

Photograph 12: DP1-B, Cracking on Crest of Jetty 2 has Increased Slightly from 2017. No cracking observed at Jetty 3 or Jetty 4 during inspection (12 September 2018)

Photograph 13: DP1-B, Downstream Slope near Station 0+300, Looking West. Minor Seepage from Downstream Toe, Similar to 2017, Entering Collection Channel to Right of Photograph (12 September 2018)

Photograph 14: DP1-B, Run-off and Seepage Collection Channel Downstream of Dike, Looking East. Seepage in Channel was Clear and at a Similar Level to 2017 (12 September 2018)

Photograph 15: DP1-B, Clear Seepage Visible from Dike Toe near Station 0+190. Less Seepage at This Location than in 2017 (12 September 2018)

Photograph 16: DP1-B, Downstream Channel and Sump near Station 0+120, Looking East. Slightly Lower Water Level at Sump Location than in 2017 (12 September 2018)

Photograph 17: DP1-B, Upstream Slope near Station 0+330, looking South. Evaporator #4 Jetty and Pump Barge in Background (12 September 2018)

Photograph 18: DP1-B, Upstream Slope looking West near Station 0+320. Evaporator #2 Jetty in Background (12 September 2018)

Photograph 19: DP1-B, Crest looking Northwest near Station 0+320 (12 September 2018)

Photograph 20: DP1-B, Evaporator #4 Jetty and Pump Barge Looking West (12 September 2018)

Photograph 21: Overview of P1 and Evaporator #4 Jetty and Pump Barge looking West from Near Station 0+400 of DP1-B. Evaporator #1 in Operation (12 September 2018)

Photograph 22: P1 Till Dividing Berm, Looking West (12 September 2018)

Photograph 23: DP2-A, West End of Dike, Looking East (12 September 2018)

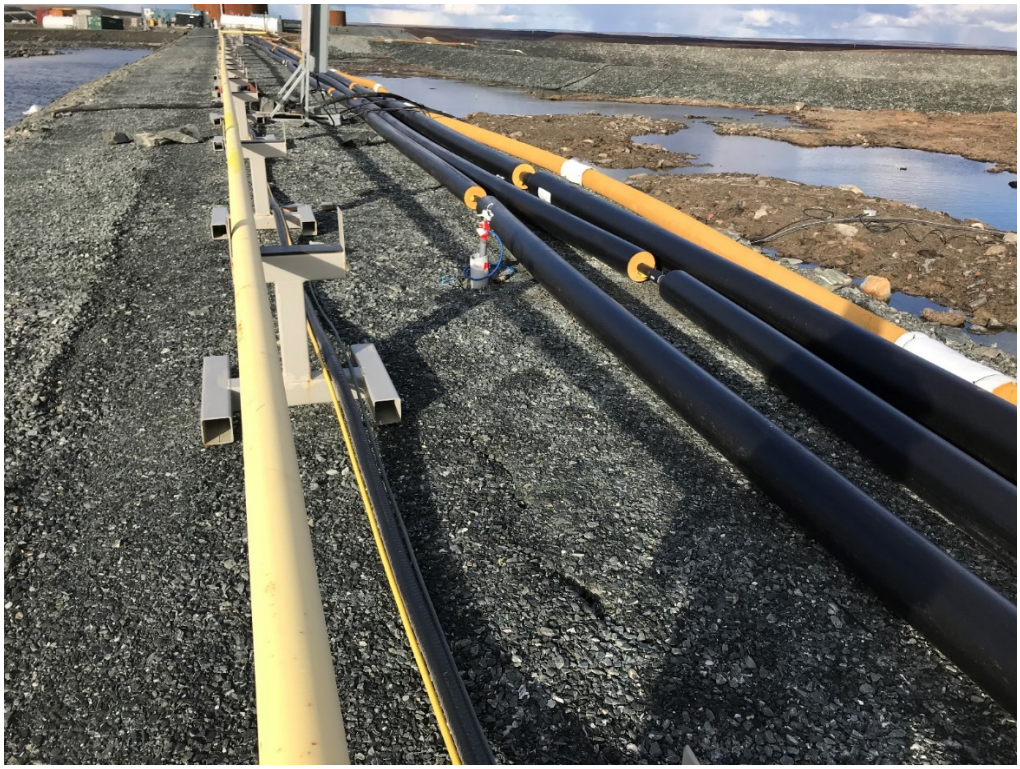
Photograph 24: DP2-A, Upstream Slope near Station 0+025, Looking East (12 September 2018)

Photograph 25: DP2-A, Downstream Slope near Station 0+70, Looking East. Mine Access Road runs along Downstream Toe of Dike (12 September 2018)

Photograph 26: DP2-A, Upstream Slope near Station 0+65, Signs of Minor Slumping at Crest, Looking West. Signs of Slumping at Crest were not Observed in 2017 (12 September 2018)

Photograph 27: DP2-A, Cracking near Station 0+100, looking West. (12 September 2018)

Photograph 28: DP2-A, Cracking near Station 0+100, looking East. The Length of the Cracking in This Area of the Dike was Similar to 2017, but the Cracks were Wider and Deeper (12 September 2018)



Photograph 29: DP2-A, Upstream Side Looking West from Near Station 0+110 (12 September 2018)

Photograph 30: DP3-A, Downstream Slope and Seepage Collection Channel, Looking Southwest near Station 0+300. More Water Ponded Downstream than in 2017 (12 September 2018)

Photograph 31: DP3-A, Upstream Slope and Pond 3, Looking Southwest near Station 0+300 (12 September 2018)

Photograph 32: DP3-A, Cracking on the Crest near Station 0+150, Looking Southwest. Cracking was Slightly Wider and Deeper than in 2017 (12 September 2018)

Photograph 33: DP3-A, Cracking on the Upstream Slope near Station 0+150 that was not Observed in 2017 (12 September 2018)

Photograph 34: DP3-A, Upstream Slope and Crest Looking Northeast near Station 0+150 (12 September 2018)

Photograph 35: View Northeast of the Saline Pond from near Station 0+150 of DP3-A. Clear Seepage Water Ponded in Downstream Collection Channel and Along Dike Toe. More Ponded Water than in 2017 (12 September 2018)

Photograph 36: DP3-A Downstream Slope and Seepage Collection Channel, looking Northeast near Station 0+40. More Ponded Water Downstream than in 2017 (12 September 2018)

Photograph 37: DP3-A, Looking Northeast at Pond 3 from near Station 0+000 (12 September 2018)

APPENDIX A-2

Permanent Water Management Facilities

Photograph 1: D-CP1, Overview of D-CP1, Google Earth Image (20 August 2017)

Photograph 2: D-CP1, Water Pipeline Ramp Upstream of Dike Near Station 1+140, Looking South. Some Minor Erosion Observed that was not Observed in 2017 (12 September 2018)

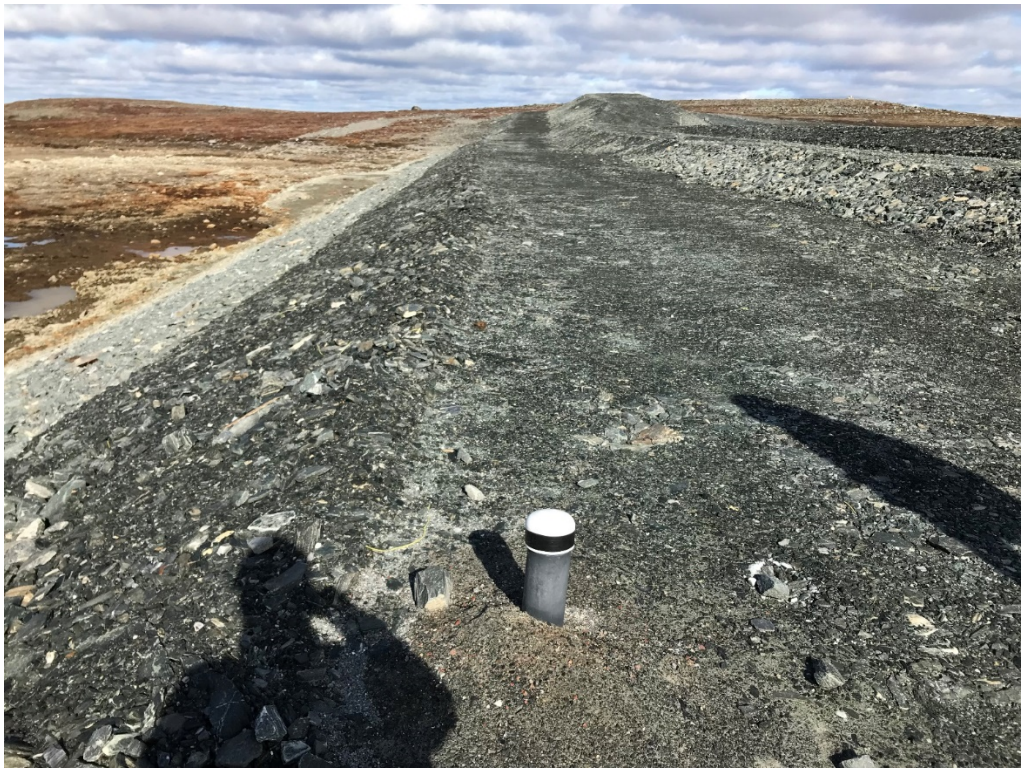
Photograph 3: D-CP1, Upstream Slope Near Station 1+140, Looking Northeast (12 September 2018)

Photograph 4: D-CP1, Cracking on Upstream Bench Crest Near Station 1+150, Looking Northeast. Length of Cracking had Increased Slightly from 2017 Observations and Minor Increase in the Widths of the Cracks (12 September 2018)

Photograph 5: D-CP1, Upstream Slope near Station 1+230, Looking North (12 September 2018)

Photograph 6: D-CP1, Upstream Slope near Station 1+290, Looking South (12 September 2018)

Photograph 7: D-CP1, Upstream Slope and Crest Near Station 1+350, Looking North (12 September 2018)

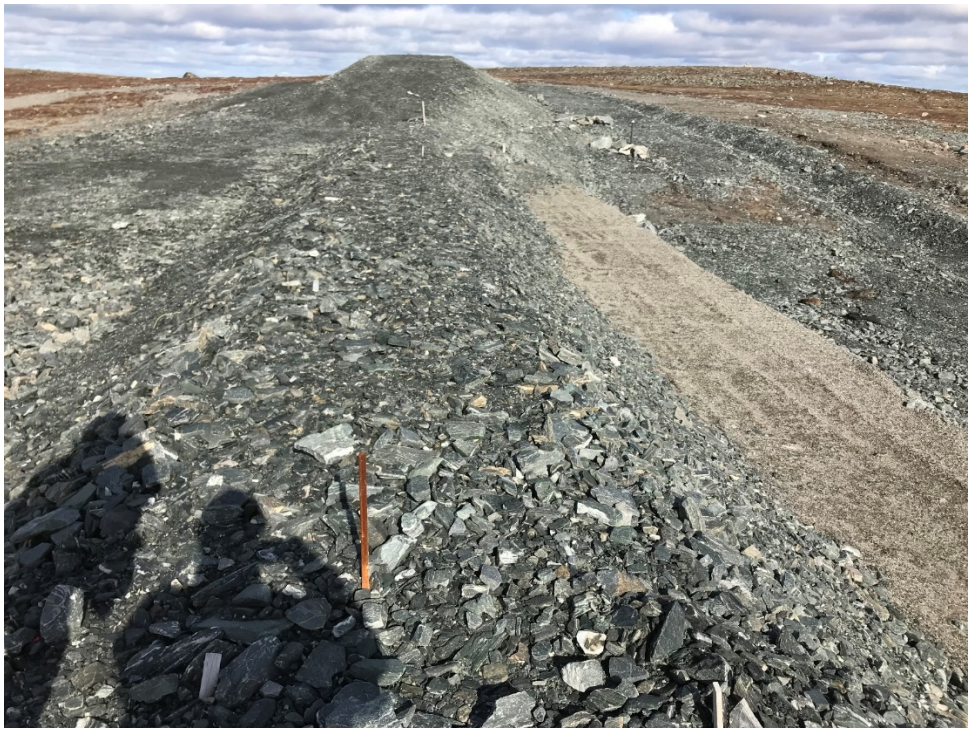


Photograph 8: D-CP1, Upstream Bench Crest Near Station 1+400, Looking North (12 September 2018)

Photograph 9: D-CP1, Cracking on Upstream Bench Crest Near Station 1+450, Looking North. Similar Condition to 2017 (12 September 2018)

Photograph 10: D-CP1, Upstream Slope Near Station 1+450, Looking South (12 September 2018)

Photograph 11: D-CP1, VGTC-03 on Upstream Bench, Station 1+460, Looking North (12 September 2018)



Photograph 12: D-CP1, Upstream Slope and Crest Near Station 1+540, Looking South (12 September 2018)

Photograph 13: D-CP1, Upstream Bench Crest Near Station 1+575, Looking South (12 September 2018)

Photograph 14: D-CP1, Crest Looking South Near Station 1+575, Looking South (12 September 2018)

Photograph 15: D-CP1, Crest Looking North Near Station 1+510 (12 September 2018)

Photograph 16: D-CP1, Crest Looking South Near Station 1+420 (12 September 2018)

Photograph 17: D-CP1, Downstream Slope and Crest Looking South Near Station 1+250 (12 September 2018)

Photograph 18: D-CP1, Crest Overview Looking Northeast Near Station 1+160 (12 September 2018)

Photograph 19: D-CP1, Cracking on Downstream Bench Near Station 1+145, Looking Northeast. Cracks are Wider and Deeper Than in 2017 (12 September 2018)

Photograph 20: D-CP1, Downstream Slope and Seepage Collection Channel Looking South, Near Station 1+550 (12 September 2018)

Photograph 21: D-CP1, Downstream Slope Looking Northwest, Near Station 1+250 (12 September 2018)

Photograph 22: D-CP1, Downstream Slope Looking Southwest, Near Station 1+210 (12 September 2018)

Photograph 23: D-CP1, Downstream Sump Looking Northeast Near Station 1+220 (12 September 2018)

Photograph 24: D-CP1, Downstream Sump Looking Southeast Near Station 1+240 (12 September 2018)

Photograph 25: D-CP1, Downstream Sump and Downstream Slope Looking South Near Station 1+240 (12 September 2018)

Photograph 26: D-CP1, Cracking/Slumping in North Side of Downstream Sump, Looking East. Similar Condition to 2017 (12 September 2018)

Photograph 27: CP1 Jetty 1, Southeast Slope Overview, Looking North (13 September 2018)

Photograph 28: CP1 Jetty 1, Northwest Slope, Looking Northeast (13 September 2018)

Photograph 29: Jetty 1, Southeast Slope, Looking Southwest (13 September 2018)

Photograph 30: General overview of D-CP5, Berm 3, Channel 5, and the Saline Pond, Google Earth Image (August 2017

Photograph 31: D-CP5, Upstream Bench at Southwest Abutment Looking Northeast Near Station 1+025 (12 September 2018)

Photograph 32: D-CP5, Upstream Slope, Looking South Near Station 1+170 (12 September 2018)

Photograph 33: D-CP5, Upstream Crest Looking Southwest Near Station 1+170 (12 September 2018)

Photograph 34: D-CP5, Cracking on Upstream Bench Looking Northeast Near Station 1+180. This Cracking was not Observed in 2017 (12 September 2018)

Photograph 35: D-CP5, Cracking on Upstream Bench Looking Northeast Near Station 1+185. This Cracking was not Observed in 2017 (12 September 2018)

Photograph 36: D-CP5, Upstream Crest Looking Southwest Near Station 1+250 (12 September 2018)

Photograph 37: D-CP5, Upstream Crest Looking Southwest Near Station 1+300 (12 September 2018)

Photograph 38: D-CP5, Downstream Slope and Crest Overview Looking Southwest Near Station 1+275 (12 September 2018)

Photograph 39: D-CP5, Crest Overview Looking Southwest Near Station 1+250 (12 September 2018)

Photograph 40: D-CP5, Downstream Bench Cracking looking Northeast Near Station 1+180. Similar Condition to 2017 (12 September 2018)

Photograph 41: D-CP5, Cracking in Downstream Slope Looking Southwest Near Station 1+175. This Cracking was not Observed in 2017 (12 September 2018)

Photograph 42: D-CP5, Downstream Slope and Pump Location Looking Northeast Near Station 1+170 (12 September 2018)

Photograph 43: CP5, Jetty 5 and Pumping Station. South Slope of Jetty, Looking West (12 September 2018)

Photograph 44: CP5, Jetty 5 Pipeline and Pumping Station. North Slope of Jetty, Looking West (12 September 2018)

Photograph 45: CP5, Jetty 5 Intake and Southwest Toe Looking Southeast (12 September 2018)

Photograph 46: Saline Pond, Looking Southeast (12 September 2018)

Photograph 46: Saline Pond, Cracking in Northwest Perimeter Berm Looking Southeast. Cracking and Slumping have Increased Slightly from 2017 (12 September 2018)

Photograph 47: Saline Pond, Southwest Perimeter Berm Looking Northwest, Cracking Along Downstream Crest. This Cracking was not Observed in 2017 (12 September 2018)

Photograph 48: Saline Pond, Southeast Perimeter Berm Cracking in Upstream Crest, Looking Northwest. This Cracking was not Observed in 2017 (12 September 2018)

Photograph 49: Saline Pond, Area of Possible Settlement Identified During 2017 Inspection, Near Toe of Northwest Perimeter Berm, Looking Southwest. No Visible Change from 2017 (12 September 2018)

Photograph 50: Saline Pond, Downstream Slope of the Northwest Perimeter Berm and Water Ponded Between Saline Pond and DP3-A (12 September 2018)

Photograph 51: Channel 1, Outlet of Channel at East End, Looking Northeast towards CP1 (13 September 2018)

Photograph 52: Channel 1, Small Slump and Crack along the South Slope Crest About 30 m West from Outlet of Channel (13 September 2018)

Photograph 53: Channel 1, Looking Upstream Northwest Towards Culvert 16 (13 September 2018)

Photograph 54: Channel 1, Outlets of Culvert 16 Looking Southwest (13 September 2018)

Photograph 55: Channel 1, Inlets of Culvert 16 and Pond Area H12. Construction Was Not Complete in This Area at the Time of the Site Visit (13 September 2018)

Photograph 56: Channel 1, Inlets of Culvert 16, Looking Northeast (13 September 2018)

Photograph 57: Channel 2, Unlined Extension of East End of Channel 2, Looking Northwest (11 September 2018)

Photograph 58: Channel 2, Start of Lined Channel at East End, Looking Northwest (11 September 2018)

Photograph 59: Channel 2, Eastern End, Looking Northwest (11 September 2018)

Photograph 60: Channel 2, Western Section, Looking East (11 September 2018)

Photograph 61: Channel 2, West End Near Outlet, Looking West. Some Water Ponded in Base of Channel (11 September 2018)

Photograph 62: Channel 2, Outlet of Channel at West End, Looking West (11 September 2018)

Photograph 63: Channel 3, Beginning of Alignment at Station 0+000 Looking Southwest (13 September 2018)

Photograph 64: Channel 3, Near Station 0+140 Looking West (13 September 2018)

Photograph 65: Channel 3, Extent of Completed Channel Looking East (13 September 2018)

Photograph 66: Channel 3, Alignment of Remaining Construction Looking West from the West end of the Completed Channel (13 September 2018)

Photograph 67: Channel 5, Looking Northeast from Near Station 0+250 (12 September 2018)

Photograph 68: Channel 5, Looking West from Near Station 0+250

Photograph 69: Channel 5, Looking West Near Station 0+220 (12 September 2018)

Photograph 70: Channel 5, Looking West Near Station 0+145. Less Water Ponded in this Area Compared to 2017 (12 September 2018)

Photograph 71: Channel 5, Water Ponded in Channel and Cracking Along South Slope of Trench Near Station 0+050, Looking Southwest. This Cracking was Not Observed in 2017 but Access to This Area was Limited due to Water Levels and Saturated Conditions in the Tundra (12 September 2018)

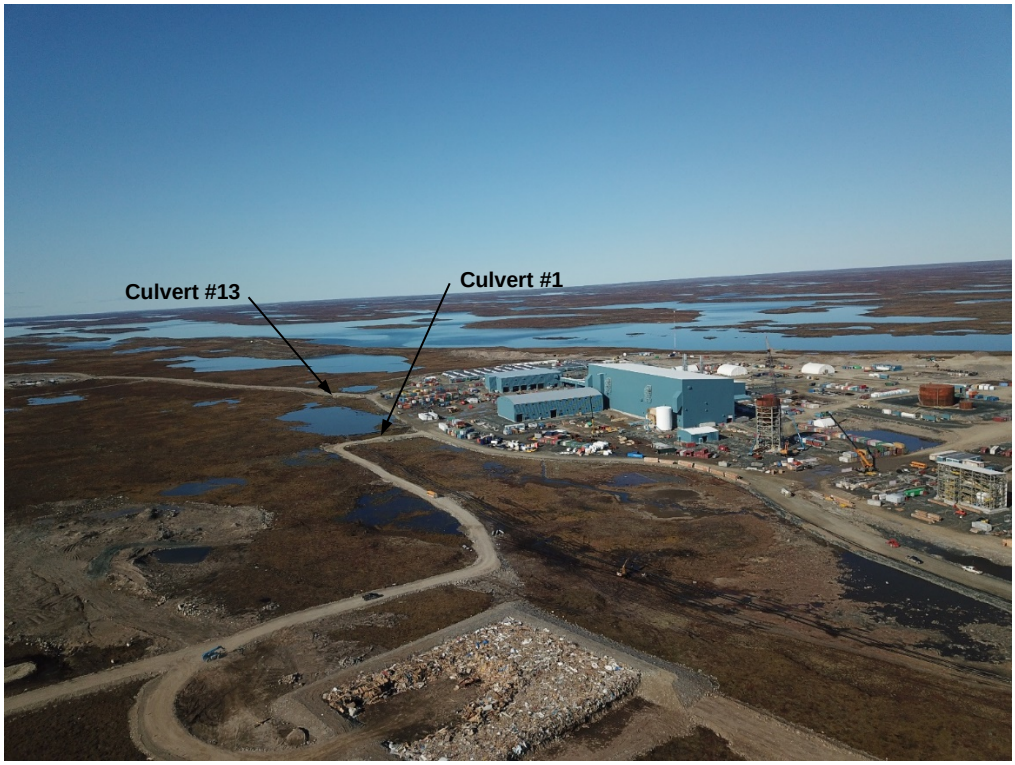
Photograph 72: Berm 3, Upstream Slope and Crest Near Abutment with D-CP5, Looking Northwest (12 September 2018)

Photograph 73: Berm 3, Downstream Slope and Crest Near Abutment with D-CP5, Looking Northwest (12 September 2018)

Photograph 74: Berm 3, Upstream Slope and Crest Near Station 0+060, Looking Southeast (12 September 2018)

Photograph 75: Berm 3, Downstream Slope and Crest Near Station 0+060, Looking Southeast (12 September 2018)

Photograph 76: Berm 3, Upstream Slope, Some Cracking Near Station 0+280, Looking North. This Cracking was Not Observed in 2017 (12 September 2018)



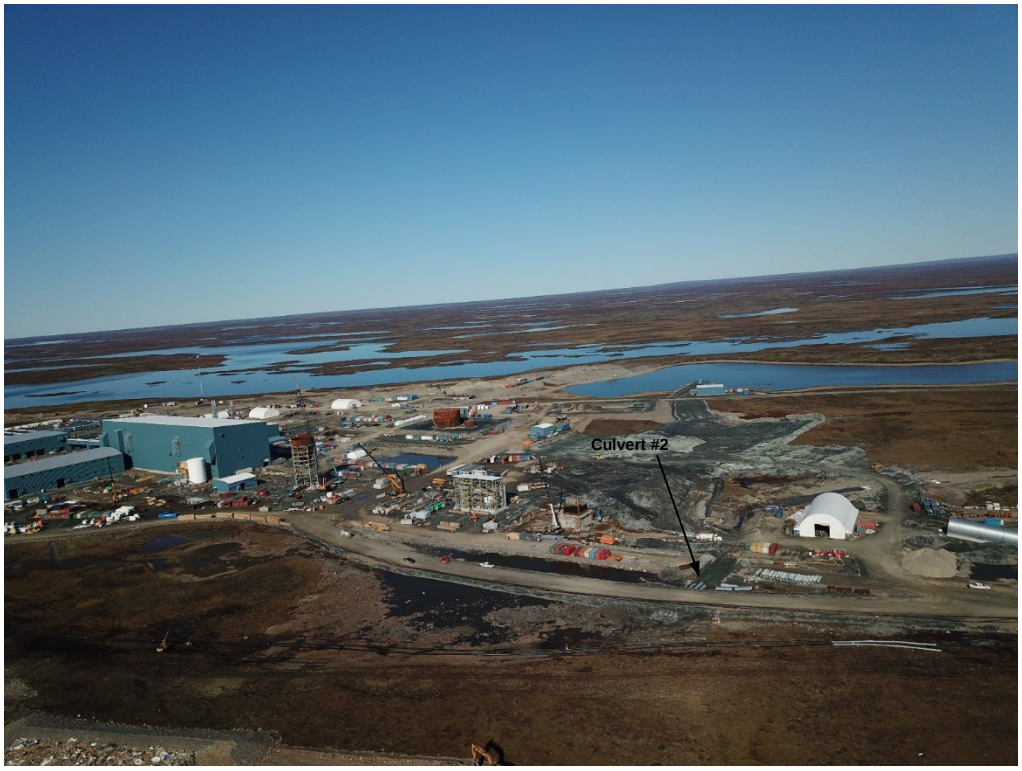
Photograph 77: Berm 3, Downstream Slope, Some Cracking Near Station 0+280, Looking North. Cracking was not Observed in 2017 (12 September 2018)

Photograph 78: Berm 3, Upstream Slope, Erosion at Toe and Along Slope from Previous High Water Mark, Near Station 0+230, Looking Northwest (12 September 2018)

APPENDIX A-3

Site Roads, Culverts, and Tiriganiaq and Wesmeg Areas

Photograph 1: Overview of Location of Culvert #1 (AEM Drone Photo 1 September 2018)



Photograph 2: Culvert #1, Upstream Ends of Culverts, Looking Northeast (11 September 2018)

Photograph 3: Culvert #1, Downstream Ends of Culverts, Looking Northeast (11 September 2018)

Photograph 4: Overview Showing Locations of Culverts #2, 3 and 4, Google Earth Image (August 2017)

Photograph 5: Areal Photo of Main Site, Service Road and Culvert #2 Shown in Foreground (AEM Drone Photo 1 September 2018)

Photograph 6: Culvert #2, Upstream Ends of Culverts, Looking Northeast (12 September 2018)

Photograph 7: Culvert #2, Downstream Ends of Culverts, Looking Southeast. Temporary Culvert in background. Culvert #2 to be Extended and Will Connect with Channel #1 (12 September 2018)

Photograph 8: Culvert #3, Upstream Ends of Culverts, Looking North. Service Road on Right (12 September 2018)

Photograph 9: Culvert #3, Downstream Ends of Culverts into CP1, Looking Northeast (12 September 2018)

Photograph 10: Culvert #4, Upstream End of Culvert, Looking North (12 September 2018)

Photograph 11: Culvert #4, Damage to Upstream End of Culvert. Similar to 2017 (12 September 2018)

Photograph 12: Culvert #4, Downstream End of Culvert into CP1, Looking Northwest (12 September 2018)

Photograph 13: Site Road, South of Culvert #4, Looking South (12 September 2018)

Photograph 14: Main Camp Water Intake, Access Road, Looking Southeast (11 September 2018)

Photograph 15: Main Camp Water Intake, Access Road, Looking Southwest (11 September 2018)

Photograph 16: Main Camp Water Intake, Pump Shack, Looking Northwest (11 September 2018)

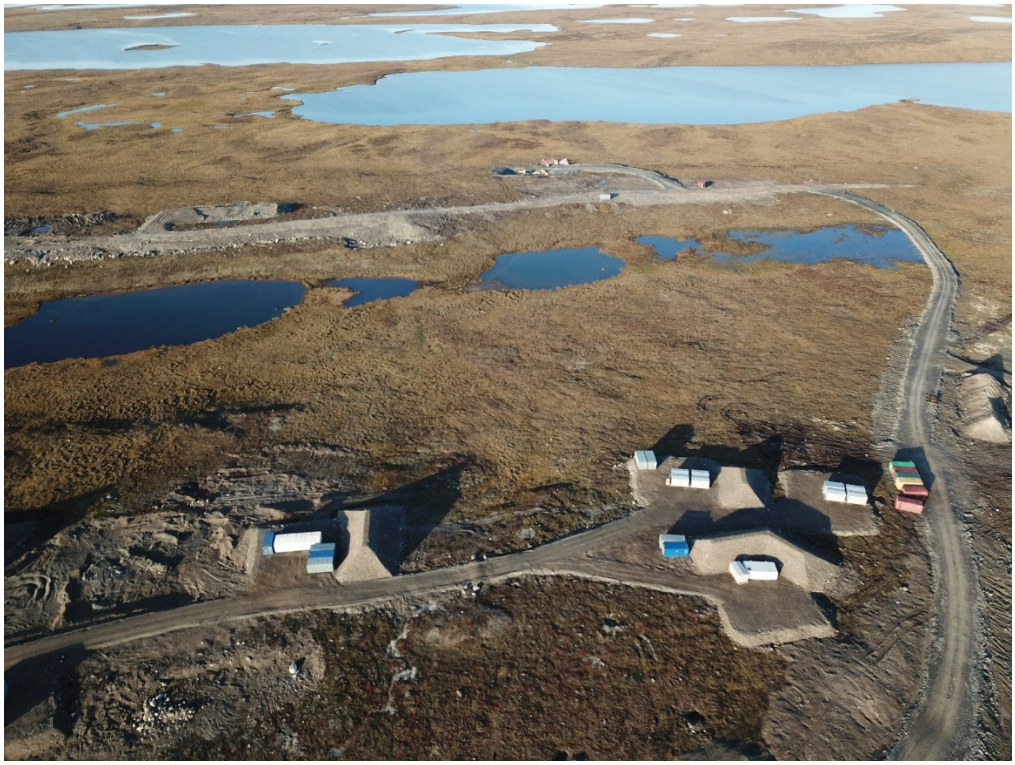
Photograph 17: Emulsion Plant Access Road, Culvert #13, Upstream Ends Near H15E (14 September 2018)

Photograph 18: Emulsion Plant Access Road, Downstream Ends of Culvert #13 Near H15E (14 September 2018)

Photograph 19: Emulsion Plant Access Road, Looking Northwest from South End of Road Near Culvert #13 (14 September 2018)

Photograph 20: Emulsion Plant Access Road, Looking Southeast from Mid-Point of Road Near Emulsion Esker. Disturbed Tundra on East Side of Road that Could Pond Water and Cause Thermal Degradation of the Permafrost. (14 September 2018)

Photograph 21: Emulsion Plant Access Road, Looking Southeast from Near Dino Access Gate, Some Minor Cracking in Road Crest (14 September 2018)



Photograph 22: Emulsion Plant Access Road, Looking Southeast Approximately Half Way Between Access Gate and Emulsion Plant Pad. Water is Ponding Adjacent to the Road Which Could Lead to Permafrost Degradation if Left (14 September 2018)

Photograph 23: Tiriganiaq Access Road, Looking West. Steel Pipes Through Road Fills in Foreground. These Pipes may be for Cable Conduits (11 September 2018)

Photograph 24: Tiriganiaq Access Road, Looking East (11 September 2018)

Photograph 25: Overview of Magazine Storage Area, Wesmeg Access Road, Vent Raise, and Borrow Area (AEM Drone Photo 1 September 2018)

Photograph 26: Wesmeg Access Road, Looking West from Near Tiriganiaq Esker (11 September 2018)

Photograph 27: Wesmeg Access Road Near Magazine Storage Area. Ponding Water and Disturbed Tundra (11 September 2018)

Photograph 28: Wesmeg Access Road, Water Ponded on South Side of Road (Lake B33A), Looking East (11 September 2018)

Photograph 29: Wesmeg Borrow, Erosion Along Western Toe, Looking North (11 September 2018)

Photograph 30: Wesmeg Vent Raise Area (11 September 2018)

Photograph 31: Wesmeg Vent Raise, Steel Pipe Culverts Through Entrance to Vent Raise (11 September 2018)

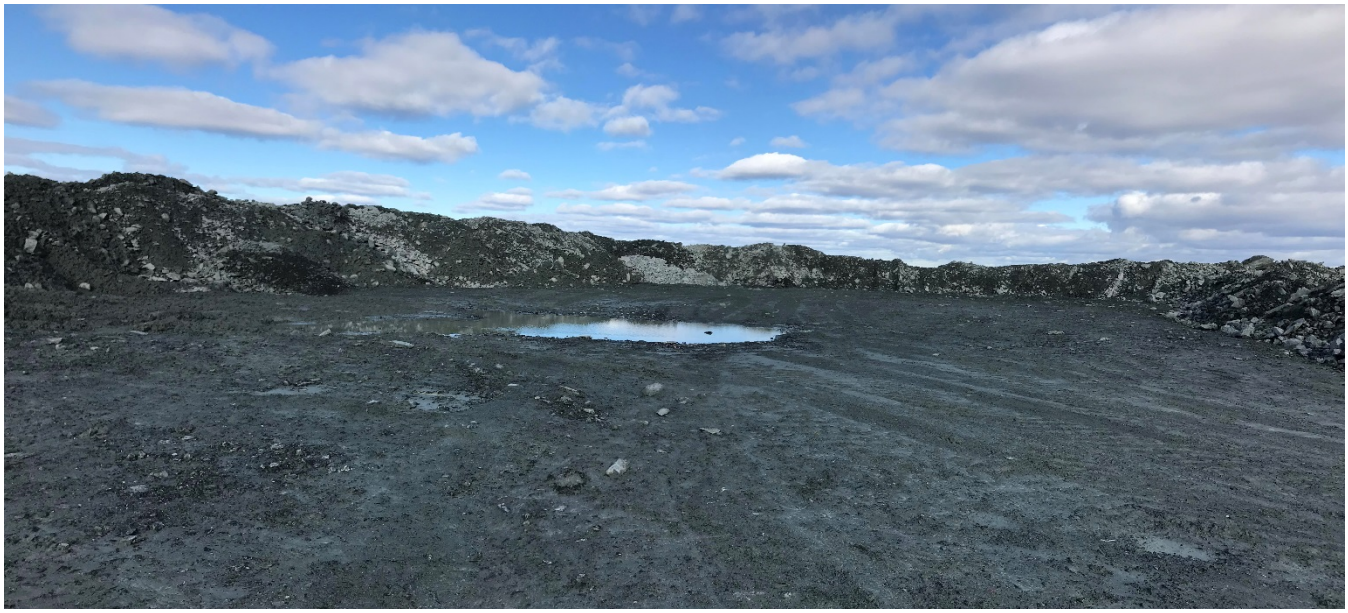
Photograph 32: Overview of Access Road to CP4 (AEM Drone Photo 1 September 2018)

Photograph 33: Access Road to CP4 (11 September 2018)

APPENDIX A-4

Temporary Ore and Waste Rock Storage Area

Photograph 1: Overview of Ore and Waste Rock Storage Area (AEM Drone Photo 1 September 2018)



Photograph 2: South Slope of Low Grade Ore Stockpile, Looking North (14 September 2018)

Photograph 3: View of Low and High Grade Ore Stockpiles, Looking North (14 September 2018)

Photograph 4: Cracking in the High Grade Stockpile, Similar to 2017 (14 September 2018)

Photograph 5: View of Top Bench of Waste Rock Pile, Safety Berms in Place, Small Pond of Water (14 September 2018)

Photograph 6: View Down Ramp from Top of Waste Rock Pile (14 September 2018)

Photograph 7: View of Low and High Grade Ore Stockpiles, Looking Southeast (14 September 2018)

Photograph 8: View of Waste Rock Stockpile, Looking South (14 September 2018)

Photograph 9: View of Crushed Ore Stockpiles, Looking Southwest (14 September 2018)

APPENDIX A-5

Other Mine Facilities

Photograph 1: Overview of Mine Facilities (Google Earth Image 2017)

Photograph 2: Landfarm, West Slope, Looking South (11 September 2018)

Photograph 3: Landfarm, Crest of West Side, Looking Southeast (11 September 2018)

Photograph 4: Landfarm, Liner Exposed on East Side, Looking Southeast (11 September 2018)

Photograph 5: Landfarm, View from Southwest corner Looking North. Material is being Excavated Hauled to Screener then Finer Material Returned to Landfarm (11 September 2018)

Photograph 6: Landfarm, South Slope, Looking East (11 September 2018)

Photograph 7: Landfarm, East Slope, Looking South (11 September 2018)

Photograph 8: Landfarm, North Slope, Looking West (11 September 2018)

Photograph 9: Landfarm Screening Area, South Slope Looking East (11 September 2018)

Photograph 10: Landfarm Screening Area, West Side, Looking North (11 September 2018)

Photograph 11: View of Landfarm Screening Area from Northwest Corner (11 September 2018)

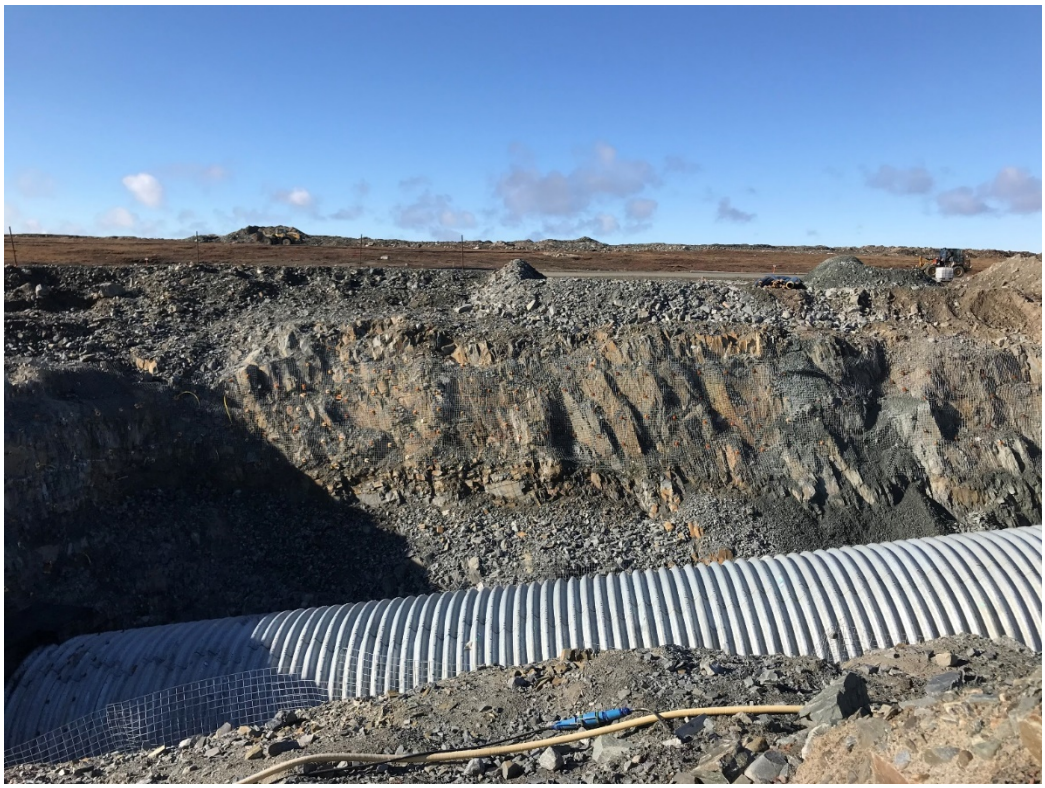
Photograph 12: Portal No. 1, View Down East Side, Looking South. Minor Erosion on Surface of Backfill (12 September 2018)

Photograph 13: Portal No. 1, View Down West Side, Looking South (12 September 2018)

Photograph 14: Portal No. 1, Looking North (12 September 2018)

Photograph 15: Portal No. 1, Excavation Around Portal, Looking West (12 September 2018)

Photograph 16: Portal No. 2, East Side, Looking South (11 September 2018)



Photograph 17: Portal No. 2, West Side, Backfill Placement In Progress, Looking South (11 September 2018)

Photograph 18: Portal No. 2, Looking North (11 September 2018)

Photograph 19: Portal No. 2, South Perimeter Berm, Looking West (13 September 2018)

Photograph 20: Portal No. 2, West Cut Slope with Rock Bolts and Mesh, Looking West (13 September 2018)

Photograph 21: Exploration Landfill, View from Southwest Corner, Looking North (13 September 2018)

Photograph 22: Exploration Landfill, Cracking on Downstream Slope at the Northwest Corner (13 September 2018)

Photograph 23: Exploration Landfill, View of North Slope looking East (13 September 2018)

Photograph 24: Exploration Landfill, Cracking on North Slope (13 September 2018)

Photograph 25: Exploration Landfill, View of Slope from Northeast Corner, Looking South (13 September 2018)

Photograph 26: Exploration Landfill, View of Top of Landfill from Northeast Corner, Looking South (13 September 2018)

Photograph 27: Operations Landfill, Overview of Original Landfill and Expansion, Looking Southwest (AEM Drone Photo 1 September 2018)

Photograph 28: Operations Landfill, View from Northeast Corner, Looking South (13 September 2018)

Photograph 29: Operations Landfill, Downstream Slope of North Berm, Looking Northeast (13 September 2018)

Photograph 30: Operations Landfill, North and East Slopes from Northeast Corner, Looking South. Some Water Ponded at Toe of Slope (13 September 2018)

Photograph 31: Operations Landfill, View of Southwest Berm, Looking Northwest (13 September 2018)

Photograph 32: Operations Landfill Expansion, View of South and East Sides, Looking West (13 September 2018)

Photograph 33: Operations Landfill Expansion, View from Southeast Corner, Looking West (13 September 2018)

Photograph 34: Operations Landfill Expansion, Northeast Slope from the Southeast Corner of the New Landfill Expansion. Slopes of New Expansion are Steeper than Original Landfill Slopes (13 September 2018)

Photograph 35: Mine Site Fuel Storage, Northeast and Northwest Containment Berm Slopes, Looking South from North Corner (12 September 2018)

Photograph 36: Mine Site Fuel Storage, Slope of Southeast Containment Berm, Looking Northeast (12 September 2018)

Photograph 37: Mine Site Fuel Storage, Overview of Interior of Facility from South Corner. Southwest Containment Berm to left of Photograph (12 September 2018)

Photograph 38: Industrial Fuel Storage, Overview of Interior of Facility, Looking West (11 September 2018)

Photograph 39: Industrial Fuel Storage, Overview of Exterior Slopes of Facility, Looking North (11 September 2018)

Photograph 40: Industrial Fuel Storage, West Berm Crest and Slope, Looking North (11 September 2018)

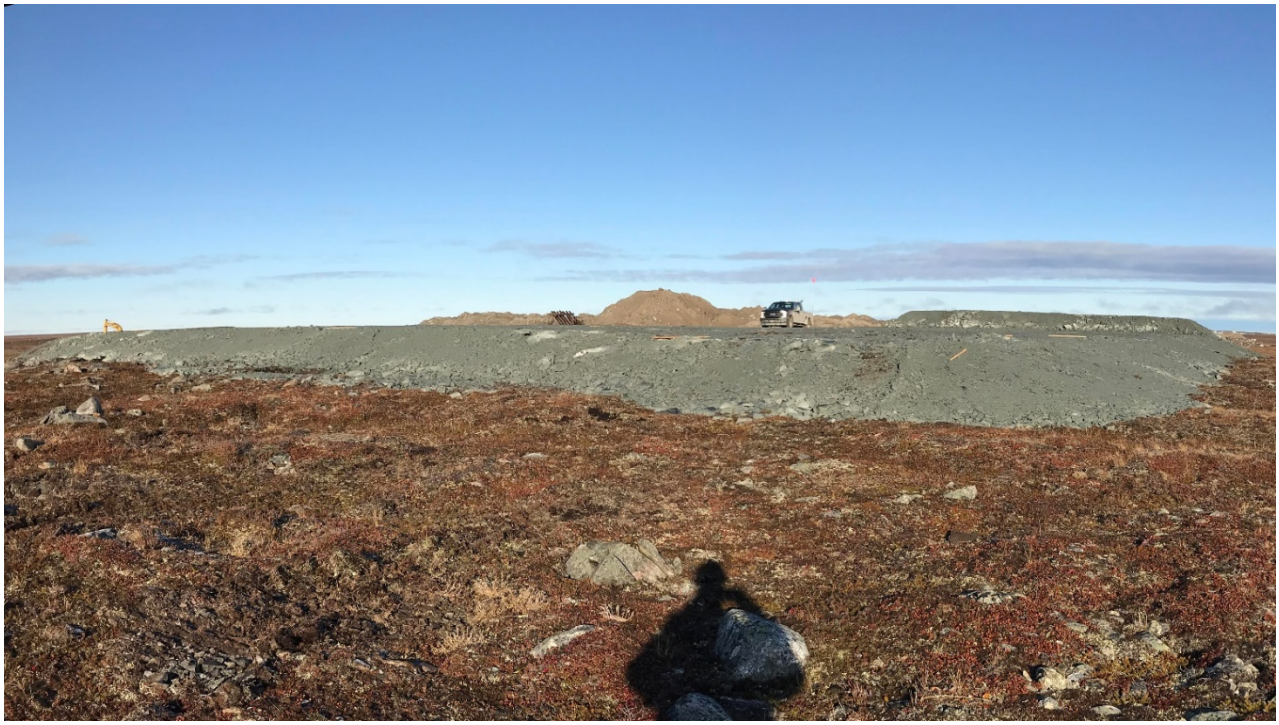
Photograph 41: Erosion of North Slope of Main Camp/Industrial Pad, Looking East. (11 September 2018)

Photograph 42: Erosion of North Slope of Main Camp/Industrial Pad, Looking Southwest. (11 September 2018)

Photograph 43: Crest of Northwest Slope of Main Camp/Industrial Pad, Looking North. (11 September 2018)

Photograph 44: Slope Along East Side of Main Camp, Looking Southwest. (11 September 2018)

Photograph 45: Slope Between Main Camp and Multi Service Building, Looking West. (11 September 2018)



Photograph 46: Water Ponded West of Industrial Fuel Storage and South of Process Plant, Looking North (11 September 2018)

Photograph 47: South Slope of Incinerator Pad, Erosion of Esker Material on Slope, Crushed Material Placed as Pad Surface, Looking East. Placement of Rockfill for Construction of Ore Storage Pad 2 In Progress to South. (11 September 2018)

Photograph 48: South Slope of East Vent Raise Pad, Looking Northeast. (12 September 2018)

Photograph 49: Temporary Cyanide Storage Pad, Looking Northwest. (13 September 2018)

Photograph 50: Effluent Water Treatment Plant South Slope, Looking East. Pipe Berm Constructed With Erodible Esker Sand to Right of Photo. (13 September 2018)

Photograph 51: Effluent Water Treatment Plant East Slope, Looking South. (13 September 2018)

Photograph 52: Emulsion Plant Pad, Overview Looking Northeast from Emulsion Storage Pad (14 September 2018)

Photograph 53: Emulsion Plant Pad, Erosion and Cracking on East Slope, Looking North. (14 September 2018)

Photograph 54: Emulsion Plant Pad, Erosion and Cracking on East Slope, Looking South. (14 September 2018)

Photograph 55: Emulsion Plant Pad, North end of East Slope, Looking South. Coarser Material and No Erosion (14 September 2018)

Photograph 56: Emulsion Plant Pad, Drainage Ditch Along North Side. (14 September 2018)

Photograph 57: Emulsion Plant Storage Pad, Overview Looking Southwest from Emulsion Plant Pad. (14 September 2018)

Photograph 58: Emulsion Plant Storage Pad, Cracking in Crest and Rut Marks in Middle of Pad From Loader, Looking Southeast. (14 September 2018)

APPENDIX A-6

Exploration Camp

Photograph 1: Overview of Exploration Camp, access road, landfarm and fuel storage. Google Earth Image (August 2017)

Photograph 2: Exploration Camp Pad, North Slope, looking West, near Fresh Water Intake Access Road (10 September 2018)

Photograph 3: Exploration Camp Pad, Erosion on Southeast Slope in Foreground of Photograph. New Genset Facility in Background (10 September 2018)

Photograph 4: Exploration Camp Pad, Sand Placed Over Cables (10 September 2018)

Photograph 5: Exploration Camp Pad, South Slope Looking Northeast, Excavator Removing Contaminated Soil from Fuel Spill (10 September 2018)

Photograph 6: Exploration Camp Pad, South Slope Looking North. Water Treatment Discharge (10 September 2018)

Photograph 7: Exploration Camp Pad, Looking West at Slope on South Side of Camp Trailers (10 September 2018)

Photograph 8: Exploration Camp Pad, Looking North at Fuel Storage Near Helicopter Pad (10 September 2018)

Photograph 9: Exploration Camp Pad, Looking Southwest, Disturbance of Tundra (10 September 2018)

Photograph 10: Exploration Camp Pad, Genset Relocation, Looking Southwest at Berm Containment (10 September 2018)

Photograph 11: Exploration Camp Pad, Genset Relocation, Interior Containment and Sump (10 September 2018)

Photograph 12: Exploration Camp Fresh Water Intake, Looking North (10 September 2018)

Photograph 13: Exploration Camp Fresh Water Intake, Looking Northeast (10 September 2018)

Photograph 14: Exploration Camp Fresh Water Intake Access Road, Pipeline Crossing, Looking Southwest (10 September 2018)

Photograph 15: Exploration Camp Fresh Water Intake, Looking West (10 September 2018)

Photograph 16: Exploration Camp Diffuser Access Road Adjacent to Camp Trailers, Looking Northeast (10 September 2018)

Photograph 17: Exploration Camp Diffuser Access Road Adjacent to Camp Trailers, Looking West (10 September 2018)

Photograph 18: Exploration Camp Diffuser Access Road, Cracking on South Side of Road, Looking West (10 September 2018)

Photograph 19: Exploration Camp Diffuser Access Road, Minor Cracking on North Side of Road, Looking East (10 September 2018)

Photograph 20: Exploration Camp Diffuser Entering Meliadine Lake, Looking North (10 September 2018)

Photograph 21: Exploration Camp Diffuser Access Adjacent to Meliadine Lake, Looking South (10 September 2018)

Photograph 22: Exploration Camp Access Road, Downstream End of Culvert on North Side of Camp, not exposed on upstream (10 September 2018)

Photograph 23: Exploration Camp Access Road, Downstream End of Culvert on North Side of Camp, not exposed on upstream (10 September 2018)

Photograph 24: Exploration Camp Access Road, Downstream End of Culvert on North Side of Camp (10 September 2018)

Photograph 25: Exploration Camp Access Road, Upstream End of Culvert on North Side of Camp (10 September 2018)

Photograph 26: Exploration Camp Access Road, Downstream Ends of Steel Pipes on Northwest Side of Camp, not exposed on upstream (10 September 2018)

Photograph 27: Exploration Camp Access Road, North Side of Road near Camp, Looking East (10 September 2018)

Photograph 28: Exploration Camp Access Road, approximately 250 m West of Camp, Erosion on Crest and Slope of Road, Looking North (10 September 2018)

Photograph 29: Exploration Camp Access Road, approximately 250 m West of Camp, Erosion on Slope of Road, Looking North (10 September 2018)

Photograph 30: Exploration Camp Access Road, Downstream End of Culvert through Road, Looking East (10 September 2018)

Photograph 31: Exploration Camp Access Road, Upstream End of Culvert through Road, Looking East (10 September 2018)

Photograph 48: Exploration Camp Landfarm, Downstream Face of South Slope, Looking Northeast (10 September 2018)

Photograph 49: Exploration Camp Cracking in Core Storage Pad. (10 September 2018)

APPENDIX B

All Weather Access Road Photographs

Photograph 1: Char River Bridge at KM6.0 Looking South (13 September 2018)

Photograph 2: Char River Bridge, Left (north) Abutment Armouring from the Upstream Side of the Right (south) Abutment (13 September 2018)

Photographs 1 to 5 were taken at KM6.0 of the Char River Bridge. Some finer grained material observed on downstream side of Left (north) Abutment, should be monitored for signs of erosion.

Photograph 3: Char River Bridge, right (south) abutment armouring, from the upstream side (13 September 2018)

Photograph 4: Char River Bridge, right (south) abutment, upstream side taken from the upstream side of the left (north) abutment (13 September 2018)

Photograph 5: Char River Bridge, downstream side of left (north) abutment, taken from the downstream side of the right (south) abutment. Finer grained material observed over coarse rockfill. (13 September 2018)

Photograph 6: At KM6.2, Downstream ends of 3 CSP culverts. Lower two culverts are 1300 mm ø, upper culvert is 700 mm ø. All are in good condition. Small erosion between culverts, consider adding armouring (13 September 2018)

Photographs 6 to 8 were taken at KM6.2 where there are 3 CSP culverts. The culverts are in good condition. Some minor erosion on the embankment between the culverts, consider additional armouring.

Photograph 7: Upstream to downstream view of 3 CSP culverts at KM6.2 (13 September 2018)

Photograph 8: Road over 3 CSP culverts at KM6.2 (13 September 2018)

Photographs 9 to 12 were taken at KM7.0 where there are 3 CSP culverts. There is minor damage to the upstream ends of two of the culverts. Some exposed sand on embankments, additional armoring should be considered.

Photograph 9: At KM7.0, downstream ends of 3 CSP culverts. Lower two culverts are 1000 mm ø, upper culvert is 700 mm ø. All are in good condition. Water ponded in lower culvert at the time of inspection (13 September 2018)

Photograph 10: Upstream ends of 3 CSP culverts at KM7.0. Minor damage to the upper and lower right culverts. Some exposed sand around the culvert inlets, additional armouring should be considered (13 September 2018)

Photograph 11: Downstream embankment and road over 3 CSP culverts at KM7.0 (13 September 2018)

Photograph 12: Upstream embankment and road over 3 CSP culverts at KM7.1 (13 September 2018)

Photographs 13 to 16 were taken at KM7.1 where there are 3 CSP culverts. The culverts and riprap appear to be in good condition.

Photograph 13: At KM7.1, downstream ends of 3 CSP culverts. Lower two culverts are 1000 mm ø, upper culvert is 700 mm ø. All are in good condition. Small flow through lower culvert at time of inspection. Riprap in good condition (13 September 2018)

Photograph 14: Upstream ends of 3 CSP culverts at KM7.1 (13 September 2018)

Photograph 15: Upstream embankment and road over 3 CSP culverts at KM7.1, looking south (13 September 2018)

Photograph 16: Downstream embankment and road over 3 CSP culverts at KM7.1, looking north (13 September 2018)

Photograph 17: At KM7.4, upstream ends of 3 CSP culverts. Lower two culverts are 900 mm ø (left) and 1000 mm ø (right), and the upper culvert is 700 mm ø. Inlet of the 900 mm has been damaged, (13 September 2018)

Photograph 18: Downstream ends of 3 CSP culverts at KM7.4 (13 September 2018). Consider extending the upper culvert to reduce erosion of the embankment.

Photographs 17 to 22 were taken at KM7.4 where there are 3 CSP culverts. The inlet of one of the culverts has been partially crushed, possibly by boulders rolling down the embankment. Finer grained material surrounds the inlet and outlet which should be monitored for signs of erosion. Also extending the outlet of the upper culvert should be considered to reduce the chance of erosion.

Photograph 19: Damaged upstream end of 900 mm culvert at KM7.4, similar to what was observed in 2017. It appears the damage may have been caused by boulders that rolled down the slope (13 September 2018)

Photograph 20: Downstream embankment and road over 3 CSP culverts at KM7.4, looking south (13 September 2018)

Photograph 21: Upstream embankment and road over 3 CSP culverts at KM7.4, looking south (13 September 2018)

Photograph 22: Road surface north of 3 CSP culverts at KM 7.4 looking north (13 September 2018)

Photograph 23: Meliadine River Bridge at KM8.0, looking southwest (13 September 2018)

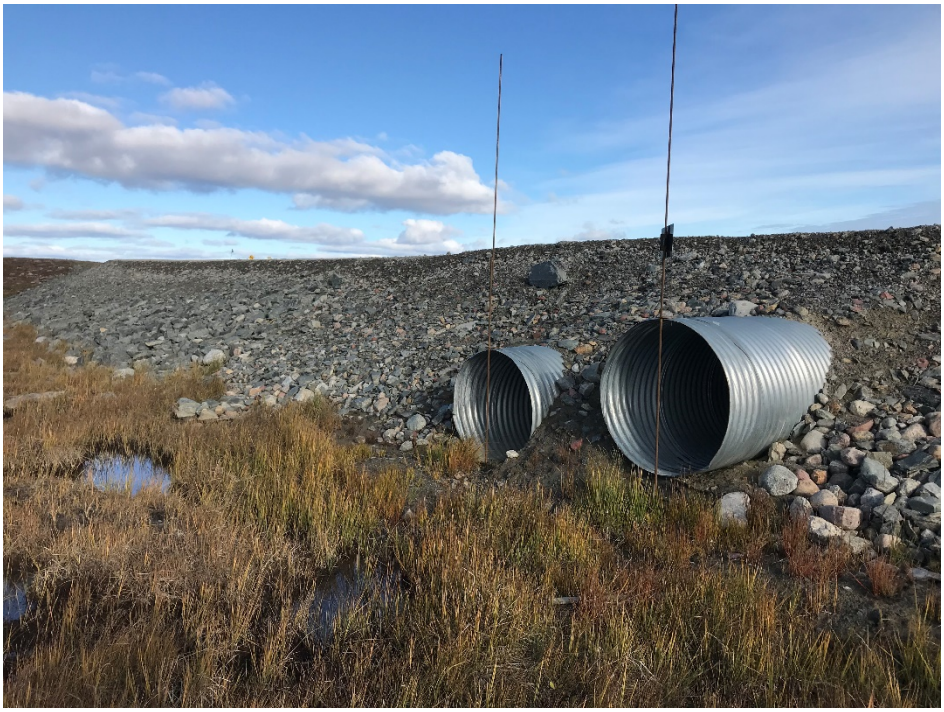
Photograph 24: Left (northeast) Abutment of the Meliadine River Bridge at KM8.0 from the downstream side of Right (southwest) Abutment (13 September 2018)

Photographs 23 to 30 of the Meliadine River Bridge were taken at KM8.0. Riprap and embankments are in good condition. Some finer grained material observed under the abutments which should be monitored for signs of erosion.

Photograph 25: Meliadine River Bridge at KM8.0. Left (northeast) Abutment from the upstream (13 September 2018)

Photograph 26: Meliadine River Bridge at KM8.0. Right (southwest) Abutment from the downstream side (13 September 2018)

Photograph 27: Meliadine River Bridge at KM8.0. Right (southwest) Abutment, from the upstream side (13 September 2018).



Photograph 28: Meliadine River Bridge at KM8.0. Embankment for the Right (southwest) Abutment, from the upstream side. The far abutment in the photo is the Left (northeast) Abutment. Riprap is in good condition (13 September 2018)

Photograph 29: Meliadine River Bridge at KM8.0 view of Right (southwest) Abutment, photo taken from the Left (northeast) Abutment. Finer grained material on abutment was observed in 2017; grass has grown on this material since 2017, no substantial erosion observed. Continue to monitor. (13 September 2018)

Photograph 30: Road leading northeast from Meliadine River Bridge at KM8.0. (13 September 2018)

Photograph 31: At KM9.1, upstream ends of two 1000 mm ø CSP culverts (13 September 2018)

Photograph 32: Downstream ends of two 1000 mm ø CSP culverts at KM9.1, (13 September 2018)

Photographs 31 to 35 were taken at KM9.1 where there are 2 CSP culverts, each 1000 mm in diameter. There is some minor deformation in the culverts under the road, no flow, water ponded below inverts.

Photograph 33: View through lower CSP culvert at KM9.1 from downstream to upstream. No observable change in deformation of culvert when compared to 2017 inspection (13 September 2018)

Photograph 34: Upstream embankment and road surface over two CSP culverts at KM9.1, looking southwest (13 September 2018)

Photograph 35: Road surface and slope north of KM9.1, looking northeast (13 September 2018)

Photograph 36: At KM9.5, upstream end of a single 1300 mm ø CSP. Culvert inlet is elevated, allowing water to pond upstream. (13 September 2018)

Photographs 36 to 39 were taken at KM9.5 where there is a single CSP culvert. It is generally in good condition, there is a small deformation of the culvert under the road. The culvert inlet is elevated resulting in water ponding on the upstream side of the road. The ponded water extends approximately 100 m north and 50 m south of the culvert location.

Photograph 37: Downstream end of a single 1300 mm CSP culvert at KM9.5 (13 September 2018)

Photograph 38: View through 1300 mm Diameter CSP Culvert at KM9.5 from the downstream end. Slight deformation of culvert under the road (13 September 2018)

Photograph 39: Road surface looking north from single CSP culvert at KM9.5 (13 September 2018)

Photograph 40: M-5 Bridge at KM10.5, photo of Left (north) Abutment, downstream side taken from the Right (south) Abutment (13 September 2018)

Photographs 40 to 47 taken of M-5 Bridge, at KM10.5. The bridge abutments are generally in good condition. No change to area previously noted as possible erosion. There is a damaged gabion on the downstream side of the Left (north) Abutment that should be replaced.

Photograph 41: M-5 Bridge at KM10.5, photo of damaged gabion on the downstream side of the Left (north) Abutment that should be replaced. (13 September 2018)

Photograph 42: M-5 Bridge at KM10.5, photo of the upstream side of the Left (north) Abutment (13 September 2018)

Photograph 43: M-5 Bridge at KM10.5, photo of the bridge and the Left (north) Abutment from the upstream side of the Right (south) Abutment (13 September 2018)

Photograph 44: M-5 Bridge at KM10.5 Right (south) Abutment, downstream side (13 September 2018)

Photograph 45: M-5 Bridge at KM10.5 Right (south) Abutment, upstream side. Previously noted as area of possible erosion, no obvious change since 2016/2017, material may have been placed in this way during construction (13 September 2018)

Photograph 46: M-5 Bridge deck at KM10.5, looking south. Speed limit sign was knocked down at time of inspection (13 September 2018)

Photograph 47: Road leading north from M-5 Bridge at KM10.5 (13 September 2018)

Photograph 48: Upstream ends of four CSP culverts at KM12.1. From left to right the diameters are 900 mm, 1300 mm, 700 mm, 1300 mm. Small dent in inlet of uppermost culvert (13 September 2018)

Photos 48 to 52 were taken along AWAR at KM12.1 where there are four CSP culverts. The embankments are generally in good condition. There is deformation of the culverts visible under the road.

Photograph 49: Downstream ends of four CSP culverts at KM12.1. Small flow observed through the lowest culvert (second from right in the photograph). Visible deformation of the culverts under the road (13 September 2018)

Photograph 50: Downstream ends of four CSP culverts at KM12.1, looking north along the embankment (13 September 2018)

Photograph 51: Upstream ends of four CSP culverts at KM12.1 looking south along the embankment (13 September 2018)

Photograph 52: Road leading north from four CSP Culverts at KM12.1 (13 September 2018)

Photos 53 and 54 were taken along AWAR at KM12.6. At this location flow is visible along the road. No culvert is present and water seeps under the road.

Photograph 53: West side of AWAR at KM12.6 where water flows along the side of the road and seeps under the road from west to east (13 September 2018)

Photograph 54: AWAR KM 12.6, ponded water on the east side of the road where it is seeping out of the road fills (13 September 2018)

Photos 55 to 58 were taken along AWAR at KM13.5. Five CSP culverts are installed at this location, three of 1300 mm ø and two of 900 mm ø. The inverts of the 900 mm culverts are elevated higher than the inverts of the 1300 mm culverts. Minor deformation of the culverts noted under the road, embankments are generally in good condition.

Photograph 55: At KM13.5, upstream ends of 5 CSP Culverts (3×1300 mm Ø; 2×900mm Ø). The 900 mm culverts are vertically elevated. Minor deformation of the culverts under the road (13 September 2018)

Photograph 56: Downstream ends of 5 CSP culverts at KM13.5 (13 September 2018)

Photograph 57: View of the embankment and road over upstream ends of 5 CSP culverts at KM13.5 looking south (13 September 2018)

Photograph 58: View of the road leading north from 5 CSP culverts at KM13.5 (13 September 2018)

Photographs 59 to 62 were taken at KM14.7 on the AWAR at intersection with access road to B12 Quarry. There is a single corrugated HDPE culvert under the B12 access road. The culvert and road embankments are generally in good condition.

Photograph 59: At KM14.7, access road to B12 Quarry. View of intersection of B12 Quarry access road with AWAR looking east. (13 September 2018)

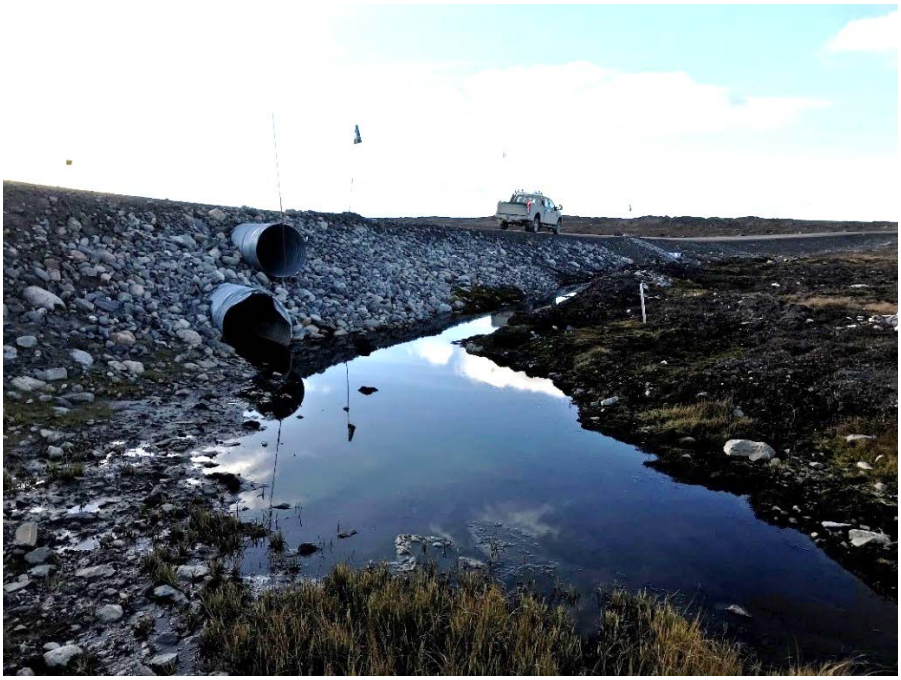
Photograph 60: View through culvert under B12 Quarry access road at KM14.7 of AWAR, no flow, small amount of ponded water within culvert (13 September 2018)

Photograph 61: Upstream end of culvert through B12 Quarry access road at KM14.7 of AWAR (13 September 2018)

Photograph 62: Looking north at AWAR from B12 Quarry access road at KM 14.7 (13 September 2018)

Photographs 63 to 66 were taken at KM16.3 where there are 3 CSP culverts. Some minor deformation of one culvert and erosion visible at the outlet of the lowest culvert.

Photograph 63: At KM16.3, upstream ends of 3 CSP culverts, looking south (13 September 2018)



Photograph 64: AWAR surface over downstream ends of 3 CSP culverts at KM 16.3 (13 September 2018)

Photograph 65: Downstream ends of three CSP culverts at KM16.3. Diameters of the culverts from left to right are: 1000 mm, 700 mm, and 1300 mm Ø. Small flow in 1300 Ø culvert and minor deformation. Some erosion visible at outlet of 1300 mm culvert (13 September 2018)

Photograph 66: AWAR looking north from KM16.3 (13 September 2018)

Photograph 67: At KM18.1, upstream ends of two CSP culverts. Upper culvert is 900 mm Ø and the lower is 1000 mm Ø. Cover over upper (900 mm Ø) culvert is thin on upstream side (13 September 2018)

Photograph 68: Damage to the inlet of the lower (1000 mm Ø) CSP culvert at KM18.1. View north along the AWAR road embankment, slope looks good, but water ponded along road. Culvert at KM18.15 visible in background (13 September 2018)

Photographs 67 to 70 were taken at KM18.1. There are 2 vertically offset, CSP culverts the upper culvert is 900 mm ø and the lower culvert is 1000 mm ø. Note that the road near KM18.1 would need to almost be flooded to reach inlet of 900 mm ø culvert. If water management in this area is a problem, suggest lowering the culvert or installing another culvert at a lower elevation. Some damage was observed on the inlet of the lower culvert, embankment is generally in good condition. A ditch on the upstream side hydraulically connects the culverts at KM18.1 to culvert at KM18.15.

Photograph 69: Downstream ends of two CSP culverts at KM 18.1 (13 September 2018)

Photograph 70: View north at slope of AWAR road embankment from the downstream ends of the culverts at KM 18.1 (13 September 2018)

Photographs 71 to 75 were taken at KM18.15 where there is a single 600 mm ø CSP culvert, the inlet of which is hydraulically connected to the inlets of the CSP culverts at KM18.1 by a ditch. The inlet of the culvert is elevated above some ponded water. Culvert and embankment are in good condition.

Photograph 71: Upstream end of a 600 mm Ø CSP Culvert at KM18.15. Water ponding below inlet. (13 September 2018)

Photograph 72: Downstream end of 600 mm Ø CSP culvert at KM18.15 and view of AWAR slope, looking south (13 September 2018)

Photograph 73: Closer view of downstream end of 600 mm Ø CSP culvert at KM18.15 (13 September 2018)

Photograph 74: View of AWAR surface and slope over culverts at KM18.15 and KM 18.1, looking south (13 September 2018)

Photograph 75: AWAR surface looking north from KM18.15 (13 September 2018)

Photograph 76: Water ponding on the west side of the road at KM19.5, looking south. Installation of a culvert should be considered (14 September 2018)

Photographs 76 and 77 were taken at KM19.5 water is ponding on the west side of the AWAR, reportedly the water ponds here year-round and can reach as high as half way up the embankment. Installation of a culvert at this location should be considered.

Photograph 77: East side of AWAR at KM19.5 where water is ponding on the west side, looking south (14 September 2018)

Photograph 78: At KM21.2 where water is ponding on the west side of the AWAR, looking north (14 September 2018)

Photographs 78 to 80 were taken at KM21.2 where water is ponding on the west side of the AWAR. There are no culverts present at this location. Water flowed over the road at this location during freshet. A straw log has been placed on the east side of the road to manage erosion. It is recommended that a culvert be installed at this location.

Photograph 79: View of the east side of the AWAR at KM21.2 where water is ponding on the west side of the road, looking south. (14 September 2018)

Photograph 80: At KM21.5, a straw log on east side of the road. Water reportedly flows over the road during spring freshet at this location. (14 September 2018)

Photographs 81 to 84 were taken at KM21.7. There are two 170 mm outside ø pipes, vertically offset. Mine personnel reports that the road was excavated at this location this spring to allow water to drain. The capacity of the pipes may be inadequate, or pipes could have been frozen/blocked causing water to backup. Installation of larger diameter culvert should be considered at this location.

Photograph 81: At KM21.7, view of the upstream ends of two steel pipes, each with an outside diameter of 170 mm. Water is ponded year-round at this location. Mine personnel reported that during freshet it was necessary to excavate the road at this location to let the water drain (14 September 2018)

Photograph 82: At KM21.7, view of the upstream ends of two steel pipes, looking north (14 September 2018).

Photograph 83: Downstream ends of two 170 mm Ø steel pipes at KM21.7 (14 September 2018)

Photograph 84: Straw logs placed on west side of the road, south of the steel pipes at KM21.7 (14 September 2018)

Photographs 85 to 88 were taken at KM22.3. There are two 160 mm ø steel pipes that are vertically offset. Both pipes were clear with no flow. Water is ponding on the upstream (west) side of the road. Inverts of culverts are elevated above the ponded water. Consider lowering the culverts to reduce ponding.

Photograph 85: At KM22.3, upstream ends of two 160 mm Ø steel pipes that are vertically offset. Water is ponded on the upstream side (14 September 2018)

Photograph 86: Upstream ends of two steel pipes at KM22.3, looking north (14 September 2018)

Photograph 87: Downstream ends of two steel culverts at KM22.3 looking south (14 September 2018)

Photograph 88: View of the road north from KM22.3 (14 September 2018)

Photographs 89 and 90 were taken at KM22.7 where water is ponded on the east side of the road. Wet soil was observed on the west side of the road indicating seepage through the road. There is no culvert at this location. Consider installation of culvert.

Photograph 89: Ponded water on the east side of the AWAR near KM22.7. No culvert at this location (14 September 2018)

Photograph 90: East side of the AWAR at KM22.7, looking north. Wet soil observed near toe of embankment. (14 September 2018)

Photographs 91 through 93 were taken at KM25.8 where there is a single HDPE corrugated 600 mm ø culvert. Some damage and granular material partially blocking the inlet of the culvert. Culvert should be cleaned out to re-establish capacity.

Photograph 91: Damaged upstream end of corrugated 600 mm Ø HDPE culvert at KM25.8. Inlet is partially blocked and should be cleaned out. (14 September 2018)

Photograph 92: Downstream end of corrugated 600 mm Ø HDPE culvert at KM25.8 (14 September 2018)

Photograph 93: Road over single corrugated HDPE culvert at KM25.8, looking south (14 September 2018)

Photograph 94: Upstream ends of two 160 mm Ø steel pipes at KM26.2. The lower pipe is bent upwards and should be replaced. The inlets are elevated close to road surface and nearly covered by road fill, consider lowering and extending (14 September 2018)

Photographs 94 and 95 were taken at KM26.2 where there are 2 vertically offset, 160 mm ø steel pipes. The lower pipe is bent upwards. The Inlets are elevated close to the road surface elevation and are nearly covered by road fill. Replacing the bent pipe and lowering and extending the inlets should be considered.

Photograph 95: Downstream ends of two steel pipes at KM26.2 (14 September 2018)

Photograph 96: Upstream ends of three 700mm Ø CSP culverts at KM26.5. Minor sediment buildup in the bottom of the culverts shouldn't substantially influence flows, monitor. (14 September 2018)

Photographs 96 through 100 are at KM26.5 where there are three 700mm ø CSP culverts installed at about equal elevation. Small dents in culverts, minor deformation observed under the road. Minor sediment buildup observed in the culverts, riprap and embankments are in good condition.

Photograph 97: Downstream ends of three CSP culverts at KM26.5. Riprap and embankments are in good condition (14 September 2018).

Photograph 98: At KM26.5, road surface and embankment over culverts, looking south (14 September 2018).

Photograph 99: At KM26.5, road and embankment over culverts, looking south (14 September 2018).

Photograph 100: View of AWAR looking north from KM26.5 (14 September 2018).

Photographs 101 through 104 are at KM26.8 where there are two 160mm ø steel pipes installed, vertically offset. The inlet of the lower pipe was covered by new road fill placed in 2018. The culvert should be extended or replaced. There is some erosion evident below the outlets of both pipes.

Photograph 101: At KM26.8, upstream ends of two vertically offset 160mm Ø steel pipes. The inlet of the lower pipe has been covered during placement of new road fill, should be extended. (14 September 2018).

Photograph 102: Downstream ends of two 160mm Ø steel pipes at KM26.8. Some minor erosion of the road embankment evident beneath the outlets of both pipes (14 September 2018).

Photograph 103: At KM26.8, water ponded on west side of road north of culverts. Water is not against road, but should be monitored during higher water levels to assess if larger culverts needed. (14 September 2018).

Photograph 104: View of road surface and embankment looking south from KM26.8 (14 September 2018).

Photographs 105 through 108 are at KM27.1 where there are 3 CSP culverts installed: 900 mm, 700 mm, and 1000 mm ø. Some minor sloughing of riprap observed around the culvert inlets. Some erosion/deposition observed under culvert outlets. Otherwise embankment slope is generally in good condition.

Photograph 105: At KM 27.1, upstream ends of three CSP culverts. Some minor sloughing of riprap observed around culvert inlets. (14 September 2018)

Photograph 106: Downstream ends of three CSP culverts at KM27.1. From left to right, 1000 mm, 700 mm, and 900 mm ø. (14 September 2018)

Photograph 107: Downstream outlets of three CSP culverts at KM27.1, some minor erosion/deposition evident under outlets. Monitor and add rip-rap if further erosion occurs. (14 September 2018).

Photograph 108: Road looking north from KM27.1. (14 September 2018)

Photographs 109 and 110 are at KM28.7 where water is ponding on the east side of the AWAR. Mine personnel report that water flowed over the road in the spring. Consider installing culvert.

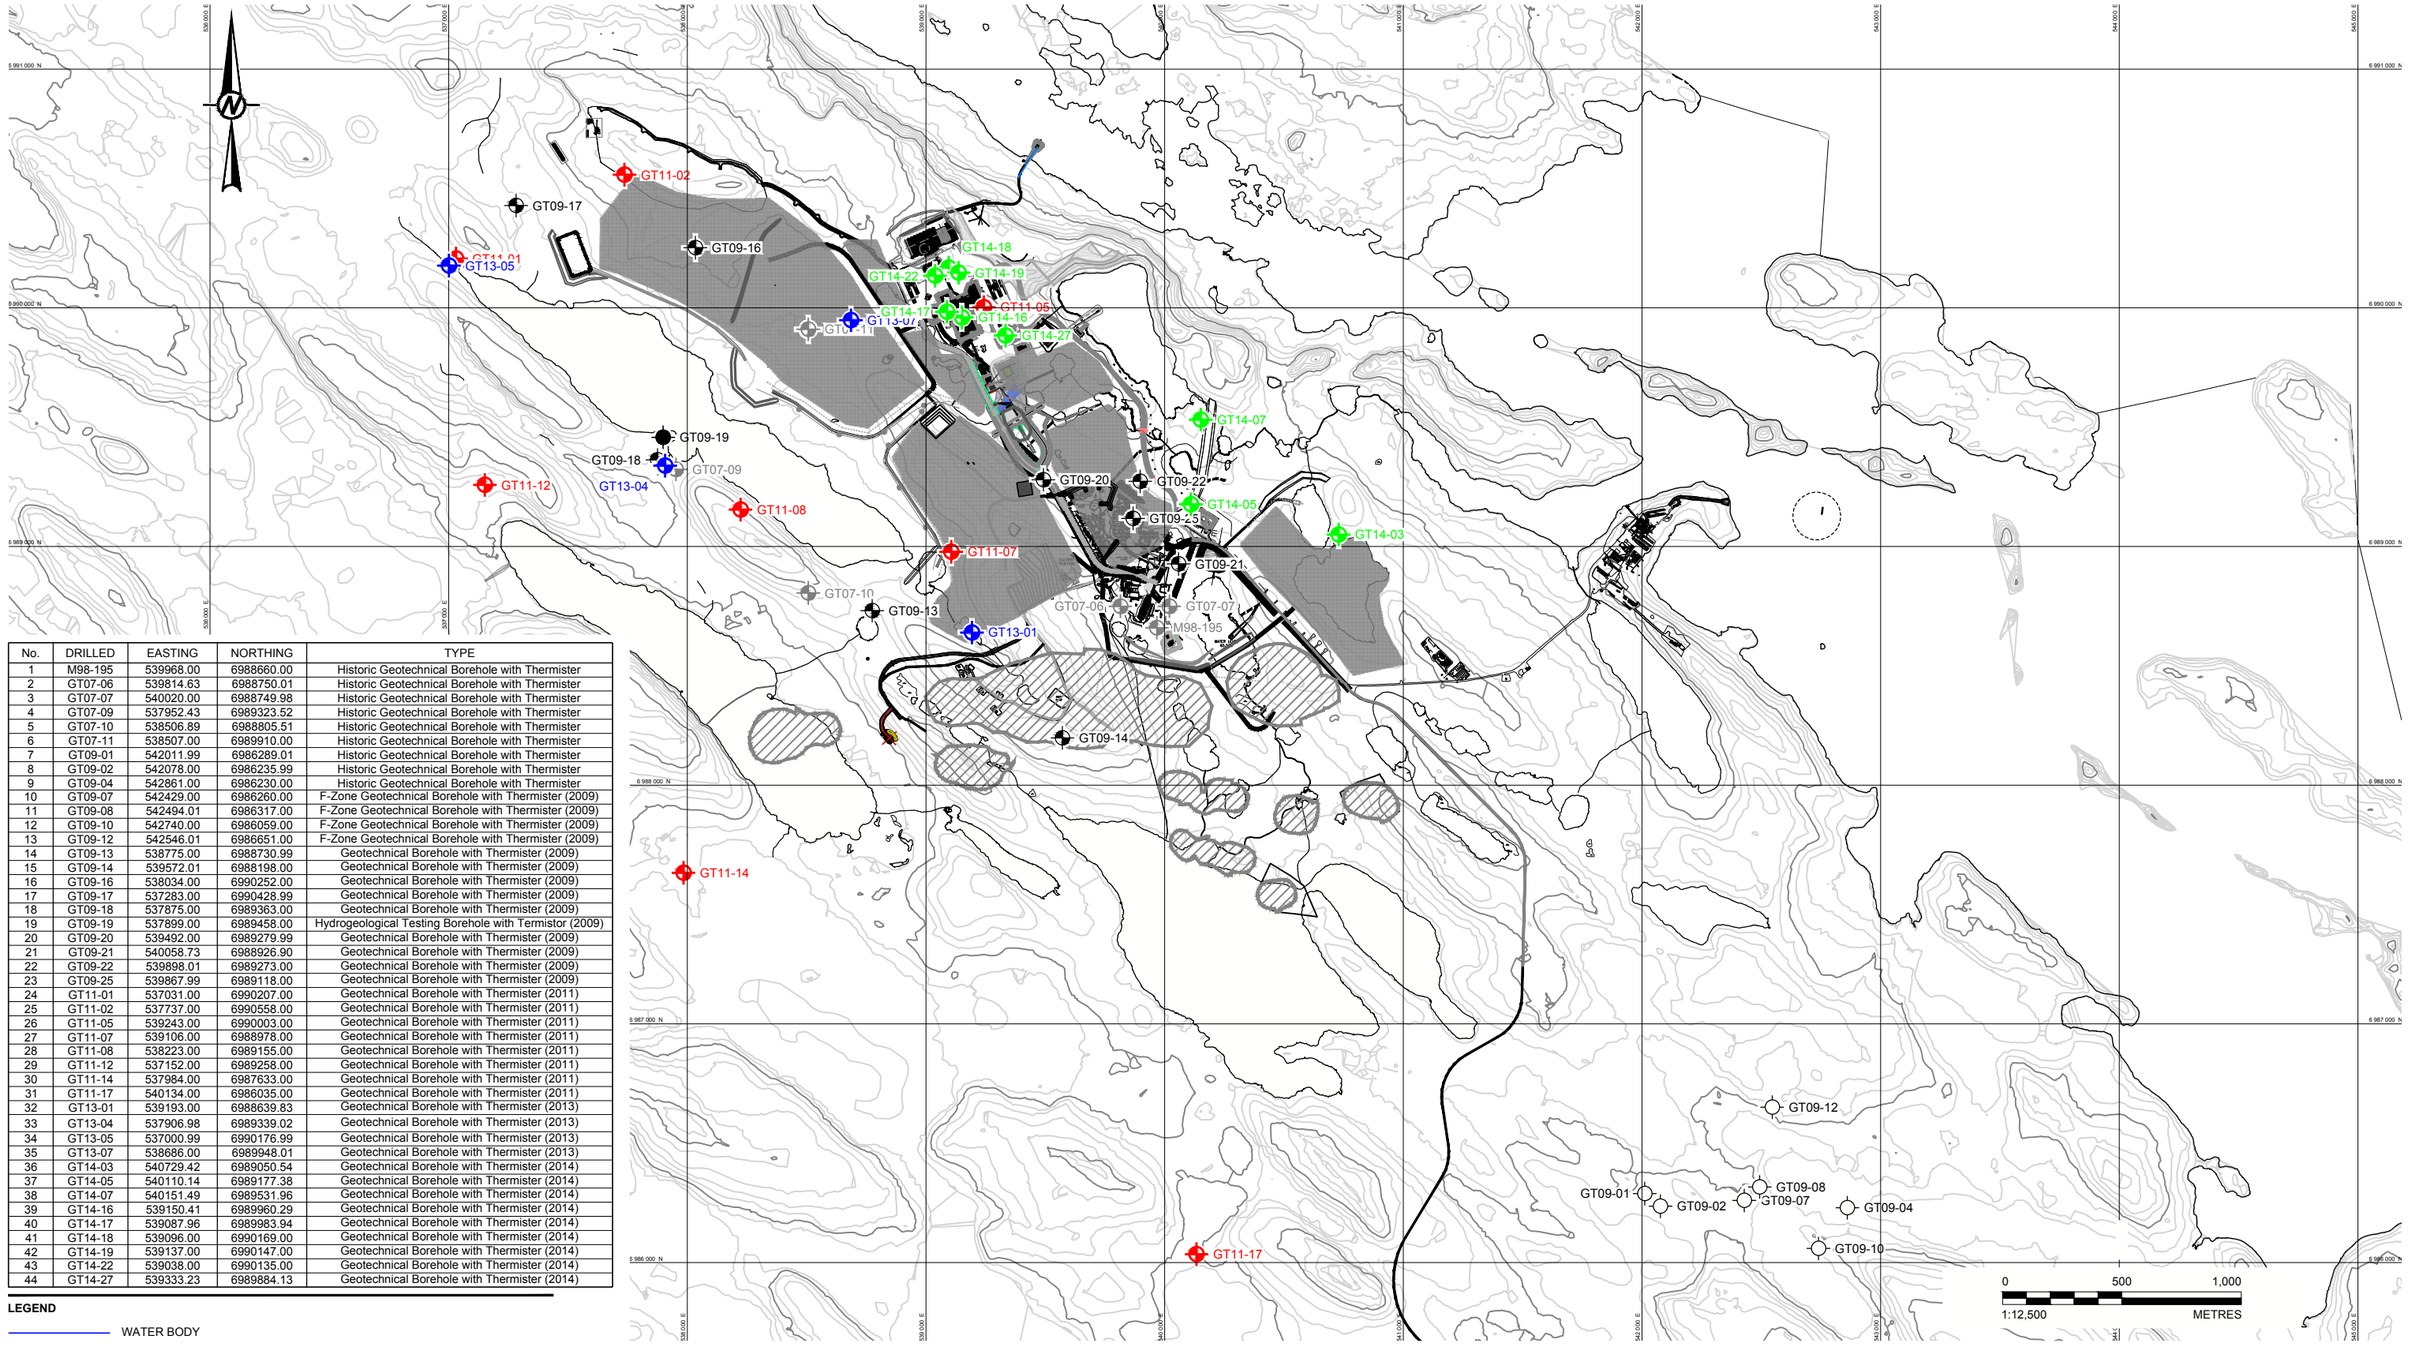
Photograph 109: At KM28.7 where water is ponding on the east side of the AWAR. Mine personnel report that water flowed over the road in the spring. Consider installing a culvert at this location (14 September 2018).

Photograph 110: Wet ground and some ponded water on the west side of the AWAR at KM28.7 (14 September 2018).

Photographs 111 through 114 are at KM29.6 where a single 500 mm ø corrugated HDPE culvert is installed. Ponding water observed on the west side of road. Culvert inlet is partially blocked by road fill and riprap and is elevated above level of ponded water. Move riprap from in front of inlet and recommend lowering culvert invert to reduce ponding adjacent to road.

Photograph 111: At KM29.6, upstream end of single 500 mm Ø corrugated HDPE culvert. Inlet to the culvert is partially blocked by riprap and road fill and is elevated above ponded water at this location. Remove riprap, clean out culvert and recommend lowering invert. (14 September 2018).

Photograph 112: View of water ponded upstream of 500mm Ø corrugated HDPE culvert at KM29.6 (14 September 2018).



Photograph 113: Downstream end of 500 mm Ø corrugated HDPE culvert at KM29.6 (14 September 2018).

Photograph 114: AWAR embankment and road over culvert at KM29.6, looking south (14 September 2018).

APPENDIX C

Instrumentation

No.	DRILLED	EASTING	NORTHING	TYPE

golder.com

Appendix B-2

Responses to geotechnical recommendations

Dikes

Annual Geotechnical Inspection Recommendation (Golder, 2018)		Priority Level (Golder, 2018)	Recommendation (s) to be Implemented?	AEM Response to Recommendation	Additional Action(s) Required	Responsible Department(s)	Expected Date of Implementation
1. Inspection and Monitoring	Geotechnical inspections should be carried out and documented for D-CP1 and D-CP5 following the schedule developed in the OMS manual. These activities were completed in 2019; however, not quite to the schdedule in the OMS. The OMS manual indicates that daily inspections should be completed and documented using the same form as the weekly inspection, which were not completed in 2018. The OMS manual does not indicate if there is seasonal variability to the frequency of documented inspections. It may be acceptable to seasonally vary the frequency of inspections, but this should be reviewed with the Engineer of Record (EoR) for the dikes and the OMS manual should be updated as required.	High	Yes	The intent, feasibility and value of daily inspections, as well as seasonality variability, are issues that will be addressed during the annual review of the OMS. The frequency of documented visual inspections will be reviewed and discussed with internal stakeholders, the Design Engineer, the EoR and members of the Independant Review Board.	Discuss visual inspection schedule with all stakeholders during annual OMS review. Update OMS as required.	Engineering	June 2019
	In addition, instrumentation should be monitored and the data should be plotted and reviewed following the schedule developed in the OMS manual.	High	Already Implemented	The current schedule of instrumentation data collection, analysis and documentation follows the schedule developed in the OMS.	No	NA	NA
	The OMS should be reviewed and updated annually and is next due for review in June 2019.	High	Already Implemented	An annual review and update of the manual is a requirement of the OMS. The 2019 review will be scheduled to occur in June.	Encourage comments/suggestions from all registered users of the OMS prior to June 2019. Schedule review with registered manual holders and update and improve manual as required.	Engineering	June 2019
	Make sure thermistors in the water management dikes are well marked so they can be located and maintained during the winter and are not damaged during snow removal operations.	High	Already Implemented	Data loggers were installed on all ground temperature cables at both D-CP1 and D-CP5 in October 2018. Each data logger and solar panel is well marked and clearly visible.	No	NA	NA
2. Water Management	Water volumes within the containment ponds should be managed to the levels defined in the OMS manual, including maintaining the water level below the elevation defined for the end of October in the OMS manual over the winter to promote freezing of the dikes.	High	Already Implemented	Upstream water elevations are checked on a daily basis during open water season and monthly during the winter as per the OMS guidelines. Deviations from the levels defined in the OMS are communicated to all stakeholders and management strategies are adjusted accordingly.	No	NA	NA
3. Dike Repair/Maintenance	Cracks and areas of settlement in the containment pond dikes should be filled and/or recontoured to close the cracks and reduce the potential for infiltration and erosion.	Medium	No	The permanent water retention dikes have been in operation for almost two years and are currently stable, with no significant geotechnical concerns identified during the Annual Inspection. Although the dikes were not designed to be resistant to water infiltration (ie. no sloping of the crests to shed surface water), it is acknowledged that the establishment of preferential water pathways within the thermal cover could lead to undesirable impacts on the stability of the structures over time. Therefore, the requirement to close the observed cracking systems on the crest of D-CP5 and the upstream crest of D-CP1 and the implementation of a regularly scheduled maintenance program will be discussed during the OMS review in June 2019 with internal stakeholders, the Design Engineer, the EoR and members of the independent Review Board.	Discuss infill of cracking and regular maintenance program with all stakeholders during annual OMS review. Update OMS as required. Schedule maintenance as required.	Engineering	June 2019
	The pipe ramp constructed out of sand upstream of D-CP1 near Stn. 1+140 is susceptible to erosion and some erosion was observed since the 2017 inspection. It is recommended that the pipe ramp be covered with a coarser rockfill to protect it from erosion.	Not Provided	Yes	The pump ramp at D-CP1 should be covered with a more robust construction material. In addition, the HDPE pipe running over D-CP1 should be covered with enough rockfill material to allow for emergency equipment/vehicle access to the dike.	Cover pump ramps with rock fill material. Protect HDPE with screened esker material/sand. Repair work will be scheduled with the appropriate department.	Engineering/E&I/Construction	Late summer 2019
	Survey monitoring plate M-3 on D-CP5 should be replaced.	Medium	Yes	Survey monuments M3 and M1 (damaged early 2019) will be replaced once the thermal cover on D-CP5 has thawed to allow hand excavation.	Continue monitoring temperatures within the dike (vertical GTC's) to determine depth of thaw and schedule survey monument replacement. Enhance protection of monuments once replacement has been completed. Restrict access to the crest of D-CP5 to authorized personnel only.	Engineering/E&I	Fall 2019
	Where access is feasible, removal of snow from the water collection pond dikes (temporary and permanent) is recommended to reduce the insulating effects of the snow, thereby allowing the temperature of the core material in the dikes and the foundations to drop as low as possible. Snow removal is more important if thermistor data is indicating that the dike and/or foundation temperatures are warmer than expected.	Medium	No	Snow clearing activities have the potential risk of damaging dataloggers, thermistor installations and trench sumps from the downstream of D-CP1 and the upstream of D-CP5. Thermistor data indicates that both dikes are generally performing as expected, with key trench and foundation conditions generally remaining below 0°C. Snow removal is therefore not currently a scheduled maintenance activity. However, snow will be cleared from the downstream toe of D-CP5 prior to freshet as a mitigation measure to prevent overtopping of the D-CP5 trench sump (an area of risk observed during freshet 2018). Thermistor records will continue to be assessed to ensure dike/foundation temperatures do not follow unexpected trends and if warmer than expected conditions arise, routine snow clearing will be reconsidered.	No	NA	NA
4. Sump/Channels	Monitor the cracking observed in the D-CP1 downstream sump berms and adjacent to the downstream channel.	Medium	Already Implemented	Regular inspection and documentation of the D-CP1 downstream sump and channels occur as part of the OMS inpsection plan for the dike.	No	NA	NA
	Recontour and/or compact the areas of cracking in the D-CP1 downstream sump berms to reduce the potential for water to infiltrate into the cracks leading to warming of the permafrost and additional thaw settlement and cracking	Medium	No	The D-CP1 downstream sump was constructed as per design and was not intended to be impervious to water infiltration. The sump area was excavated into natural ground, lined with geotextile and the slopes were covered with rip rap protection of thicknesses varying from 0.2 m to 0.4 m. This material was bucket-tamped into place. It is therefore not anticipated that any amount of recontouring or compacting would reduce the potential for water infiltration. This being noted however, routine maintenance of the sump area is specified in the OMS to prevent erosion and deterioration of the downstream water collection system. This maintenance will occur as required at the direction of the Geotechnical Engineer.	No	NA	NA
	The D-CP1 sump and downstream collection channel should be emptied in the fall/early winter to refreeze the ground around these facilities.	Medium	Already Implemented	As per the design specifications and OMS requirements for the downstream channel and sump, these facilities are emptied in the late fall prior to freeze-up.	No	NA	NA
	During open water season, keeping the water level in the downstream channel and sump low will reduce the potential for thaw of the ground around and associated settlement.	Medium	Already Implemented	Water levels in the D-CP1 sump are monitored and pump-back is automatically triggered when water levels exceed the height of the pump.	No	NA	NA

P Area

Annual Geotechnical Inspection Recommendation (Golder, 2018)		Priority Level (Golder, 2018)	Recommendation (s) to be Implemented?	AEM Response to Recommendation	Additional Action(s) Required	Responsible Department(s)	Expected Date of Implementation
1. OMS	If the P-Area dikes will continue to be used, they should be added to the OMS manual that was developed for D-CP1 and D-CP5. Geotechnical inspections and instrumentation monitoring should be carried out and documented following a schedule developed in the OMS manual.	High	No	The Annual Inspection points out that any potential failure of the P-Area dikes would now report to either CP1 or CP5 and as such, these structures are no longer considered as dams in accordance with CDA classification. AEM therefore does not consider these structures as significant enough in nature to warrant inclusion in the OMS for D-CP1 and D-CP5. However, as part of AEM's committment to exercising due dilligance, geotechnical inspections and instrumentation monitoring will continue for as long as these structures remain functioning.	No	NA	NA
2. Inspection and Monitoring	AEM personnel should continue to conduct geotechnical inspections and document visual observations such as cracking, slumping and/or seepage. Inspection reports should continue to be prepared for documentation. It is recommended that the frequency of visual geotechnical inspections be conducted weekly during freshet and monthly during the open water period.	Not Provided	Already Implemented	Visual geotechnical inspections and documentation will continue in 2019 on a monthly basis during the open water season.	No	NA	NA
	Thermistor data should continue to be collected, plotted and reviewed and pond water levels should continue to be measured and tracked.	Not Provided	Already Implemented	Pond water levels will continue to be read daily during open water season and tracked against the measured depth of thaw in the berms. Thermistor data will be collected, plotted and reviewed on a monthly basis.	No	NA	NA
	Make sure each thermistor cable is well marked so they can be located and maintained during the winter and are not damaged during snow removal operations.	Not Provided	Already Implemented	All thermistor cables are clearly marked and delineated.	No	NA	NA
	Consider adding data loggers to record the temperatures to facilitate data collection, particularly in the winter.	Low	No	Data loggers were installed for the permanent dikes in October 2018. However, owing to the temporary nature of the P-Area, the lower risk of failure and the greater accessibility of the thermistors, the expense of adding data loggers is not felt to be justified.	No	NA	NA
3. Water Management	Continue to collect and pump back seepage water as deemed necessary,in areas where seepage could impact downstream areas.	Not Provided	Already Implemented	Water levels within the collection ponds and seepage channels are monitored daily. Pumping of seepage water occurs as required and pumping records are provided daily.	No	NA	NA
	The water levels in the ponds should be reduced as much as possible in the winter to promote freezing of the dam cores. This would also increase the capacity within the ponds to manage water during the freshet, if necessary. The water levels should also be maintained as low as possible in the summer to reduce thermal warming due to water over the upstream toe of the dikes.	High	Already Implemented	Water levels within the collection ponds are monitored daily during open water season and are kept as low as possible based on the water management strategy and available treatment/discharge options. Daily meetings take place to discuss current water level statuses and targets with stakeholders. When water levels are deemed to be of concern, pumping to the P-Area is stopped and removal is maximized via transfer to the Saline Pond or active evaporation. Prior to freeze, a feasible water level target is made and reached via treatment or discharge. This target will be sufficient to ensure OMM is not reached during freshet.	No	NA	NA
4. Repair/Maintenance	If the dikes continue to be used, consideration for filling in the cracks, with additional fine rockfill or granular fill, regrading and re-compacting the slopes and crests may be warranted.	Medium	No	The Annual Inspection points out that overall, the P Area berms appear stable, with no significant geotechnical concerns identified. Therefore, owing to the temporary nature of the P Area berms and low risk of failure, AEM does not feel that the time and expense of regrading and re-compacting the slopes and crests is warranted. The exception however, would be Jetty #2 off of DP1-B. As was noted during the inspection and as documented in internal inspections throughout 2018, slumping and cracking in this area has been observed to increase over the past year. As Jetty #2 supports an evaporator and there is a risk of impacting operation of the area if the jetty fails, repair and mitigation work will be scheduled for 2019.	Schedule maintanance work with E&I for late summer 2019. Closely monitor jetty condition during summer thawing.	Engineering/E&I	September 2019
	Consider adding rockfill material to cover the till berm in P1, to protect the till and maintain its integrity if this berm is required for water management.	Low	No	The till berm in the middle of the P1 collection pond is not required for water management.	No	NA	NA
	Where access is feasible, removal of snow from the water collection pond dikes is recommended to reduce the insulating effects of the snow, thereby allowing the temperatures of the core materials in the dikes and the foundations to drop as low as possible with the potential that temperatures could get cold enough to maintain frozen conditions throughout the summer. Snow removal is more important if thermistor data indicates that temperatures within the dikes and/or foundations are warmer than expected.	Medium	No	Snow clearing activities have the potential risk of damaging thermistor installations, trench sumps and other infrastructure in the P Area. In addition, thermistor data indicates that the P Area berms will experience complete thawing during the summer/fall months, regardless of any snow removal efforts. Snow removal will therefore not be a scheduled maintenance activity.	No	NA	NA

Main Site Other

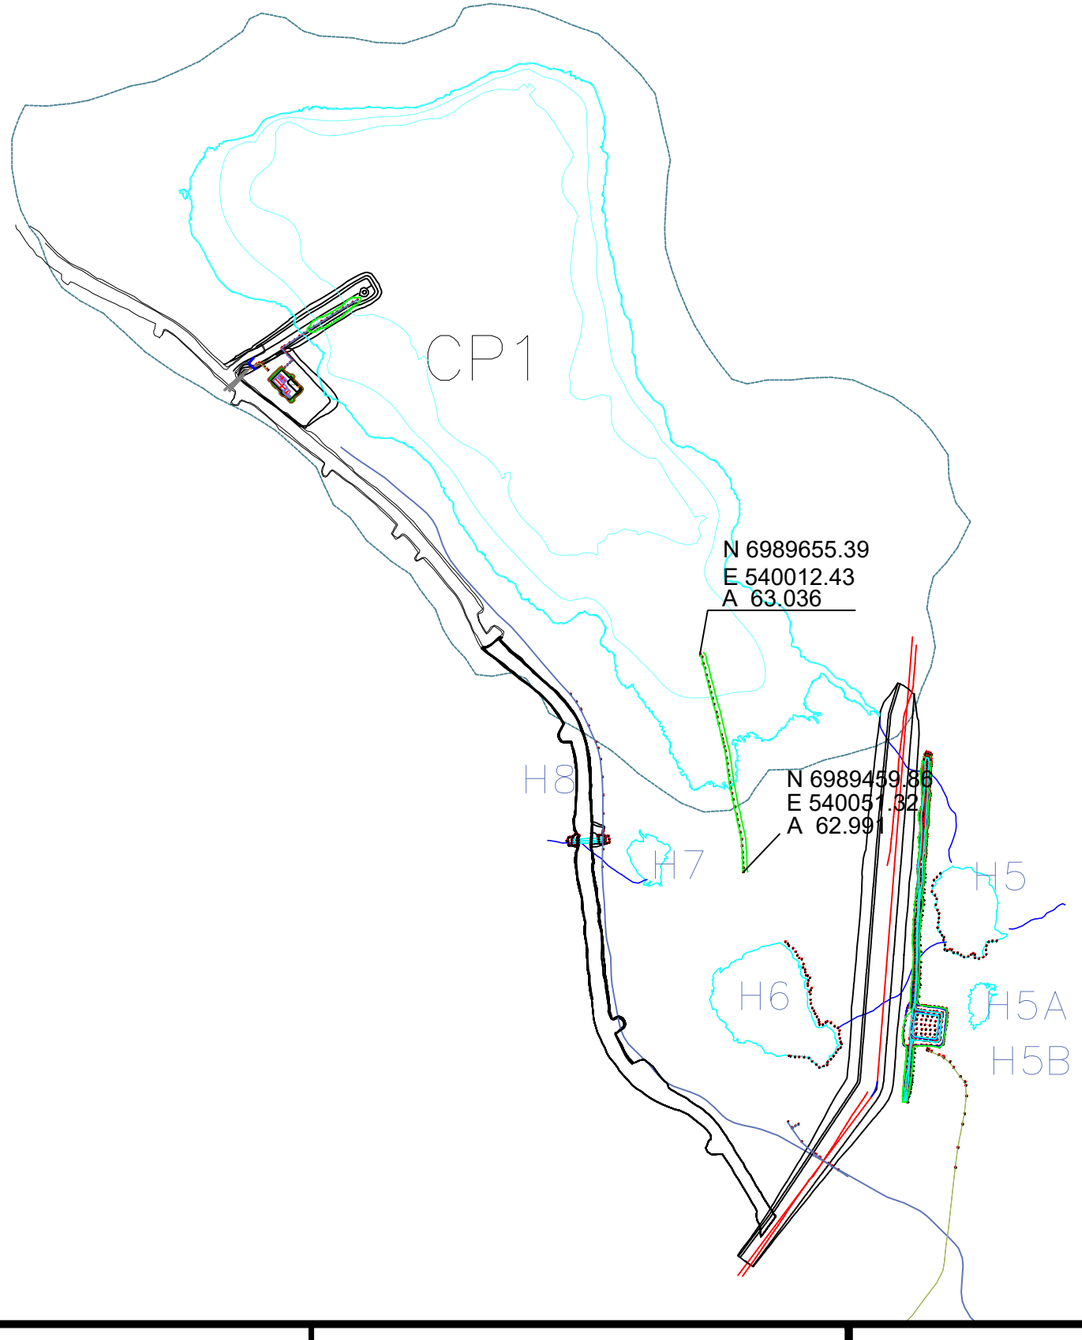
Annual Geotechnical Inspection Recommendation (Golder, 2017)		Priority Level (Golder, 2018)	Recommendation (s) to be Implemented?	AEM Response to Recommendation	Additional Action(s) Required	Responsible Department(s)	Expected Date of Implementation
1. Channel 1	The cracking and sloughing along Channel 1 should be assessed to determine if the channel is too steep and rip rap is sloughing over geotextile or if it is caused by thermal degradation or permafrost adjacent to the channel.	Medium	No	The lateral slopes of Channel 1 were locally steepened (2H:1V) for approximately 80 m to accommodate the final crusher ramp design footprint. This deviation from the original design (3H:1V) was done with the approval of the Design Engineer. As discussed in the Tetra Tech as-built report " *Construction Summary (As-Built) Report for Channel1 and Culvert #13, #1, #2, #15, #16*" issued to the NWB February 18, 2019, it is acknowledged that this localized steepening may result in the possibility of slope problems. Channel 1 will be monitored and any signs of instability, sloughing or ravelling will be corrected if observed.	Include Channel 1 in routine geotechnical inspection program and finalize inspection schedule. Prepare inspection criteria and documentation forms. Schedule any repair and/or maintenance work required.	Engineering	Pre-freshet 2019
	If possible, the channel should be kept empty through the winter to promote freezing of the permafrost around the channel.	Medium	No	Channel 1 was constructed as per design and was mechanically excavated within the active layer, lined with geotextile and covered with rip rap protection of minimum thickness 0.3 m. As the channel lies entirely within the active layer, aggradation of the underlying permafrost was neither intended nor foreseen. AEM therefore feels that snow removal throughout the winter is not worth the risk of damage to the infrastructure.	No	NA	NA
	If the bottom of Channel 1 remains below the inlets for Culvert 16, consider lowering the invert of the lowest culvert or adjust the invert of the channel, if possible, so that water will not need to pond in the channel before flowing through the culverts.	Not Provided	No	Culvert 16 was installed as per design specifications as per " *Construction Summary (As-Built) Report for Channel1 and Culvert #13, #1, #2, #15, #16*" (Tetra Tech, 2019). As with all culvert systems installed at site, performance will be monitored regularly during freshet and open water season, with any adjustments or mitigation work conducted as required.	No	NA	NA
2. Wesmeg Esker	The Wesmeg Borrow area should be recontoured and either capped with a coarser material or revegetated to reduce erosion.	Medium	Already Implemented	Rehabilitation of all site esker sources (Wesmeg, Melladine and Tiriganiaq) is scheduled to occur before the cessation of construction activities in 2019. Rehabilitation of the Wesmeg esker is currently on hold pending completion of construction activities at the West Raise. Once drilling and concrete work has finished, the excavated area will be backfilled with the material currently stockpiled on the esker and final rehabilitation of the surface will be completed.	Follow up required upon completion of construction activities.	Engineering/Construction	Fall 2019
3. Channel 5	Monitor the cracking adjacent to Channel 5.	Medium	Yes	A routine geotechnical monitoring schedule and documentation process for water management infrastructures outside of the temporary and permanent dikes is currently being formalized by the AEM Geotechnical Engineer. Channel 5 will be on the list of infrastructure to be inspected by AEM personnel.	Include Channel 5 in routine geotechnical inspection program and finalize inspection schedule. Prepare inspection criteria and documentation forms. Schedule any repair and/or maintenance work required.	Engineering	Pre-freshet 2019
	If cracking gets worse, recontouring and/or compacting the areas of cracking to close the cracks will reduce the potential for water to infiltrate into the cracks leading to warming of the permafrost and additional thaw settlement and cracking.	Medium	No	Channel 5 was constructed as per design and was not intended to be impervious to water infiltration. The channel was excavated into natural ground, lined with geotextile and the slopes were covered with rip rap protection of thicknesses approximately 0.3 m. This material was bucket-tamped into place. It is therefore not anticipated that any amount of recontouring or compacting would reduce the potential for water infiltration. It is also noted that the area adjacent to the Channel is the remnants of the access road placed for construction of Berm 3. The esker material used to construct this access road was removed and placed as rip rap protection during the final stages of Berm construction. There was no expectation that the remnants of the road would be trafficable or usable at the conclusion of construction activities in the area.	No	NA	NA
4. Berm 3	Ponding upstream of Berm 3 should be monitored to determine how much and how often ponding occurs and if Berm 3 can perform as required with the ponding.	Medium	Already Implemented	AEM currently monitors this area during freshet and throughout the open water season. Monitoring will continue in 2019. To-date, Channel 5 effectively drains to CP5 and no ponding against Berm 3 has been observed.	No	NA	NA
	The Berm 3 cover materials may be susceptible to erosion. This should be monitored, and if there is erosion, consideration should be given to placing courser material on the Berm to reduce the potential for erosion.	Medium	Yes	A routine geotechnical monitoring schedule and documentation process for water management infrastructures outside of the temporary and permanent dikes is currently being formalized by the AEM Geotechnical Engineer. Channel 5 will be on the list of infrastructure to be inspected by AEM personnel.	Include Berm 3 in routine geotechnical inspection program and finalize inspection schedule. Prepare inspection criteria and documentation forms. Schedule any repair and/or maintenance work required.	Engineering	Pre-freshet 2019
5. Portal 2	Monitor slopes above Portal 2 for rockfill instability during backfill placement.	High	Already Implemented	AEM Engineering oversaw an extensive scaling and ground support program of the rock and overburden faces at Portal 2 prior to the commencement of construction activities within the excavation. Regular, documented inspections by Ground Control Engineers were on-going during the backfill placement. Backfilling of Portal 2 was completed late in 2018.	No	NA	NA
	Snow management around and above Portal 1 and 2 may be advisable prior to freshet to reduceinflows entering the underground.	Low	Already Implemented	AEM currently clears snow around Portal 1 and Portal 2 throughout the winter and places the snow within P3 as deleterious substances may be mixed with snow. Clearing is conducted throughout the winter and is ensured in the weeks prior to freshet.	No	NA	NA
6. Exploration Landfill	A coarser rockfill layer should be placed over the decommissioned exploration landfill to reduce erosion and cracking.	Medium	No	The exploration landfill will be incorporated into Waste Rock Storage Facility 1 (WRSF1) once construction of this facility commences in 2019.	No	NA	NA
7. Saline Pond	Consideration for filling in the cracks with fine rockfill, recontouring and re-compacting the slopes and crests may be warranted to reduce the potential for infiltration into the berms that may increase the cracking and settlement.	Not Provided	No	A routine geotechnical monitoring schedule and documentation process for water management infrastructures outside of the temporary and permanent dikes is currently being formalized by the AEM Geotechnical Engineer. The perimeter berm of the Saline Pond will be on the list of infrastructure to be inspected by AEM personnel.	Include Saline Pond in routine geotechnical inspection program and finalize inspection schedule. Prepare inspection criteria and documentation forms. Schedule any repair and/or maintenance work required.	Engineering	Pre-freshet 2019
	Monitor the downstream side of the perimeter berm for ponding water and consider diverting it or pumping it so it does not seep into the saline pond and warm the foundation below the berm.	Not Provided	Yes	Monitoring is conducted site-wide as a means to identify areas of concern/seepage. The perimeter berm around the Saline Pond will specifically be added to the inspection template as an area of concern.	Add specific item to monitor the downstream side of the perimeter berm at Saline Pond for ponding. This will be added to the freshet and water structure inspection templates.	Environment	Pre-freshet 2019
	Where possible, try not to allow seepage water from DP3-A to pond against the Saline Pond berm to avoid permafrost degradation.	Medium	Already Implemented	AEM actively pumps the trench downtream of DP3-A during freshet and the open water season. In 2018, the trench pump was upgraded from a 3-hp submersible pump to a 5-hp submersible in order to ensure the trench remains below the elevation of the pump.	No	NA	NA
8. Industrial Pad	Where erosion is occuring on the slopes of the pads, the existing materials should be regraded and compacted, and a coarser material should be placed to further reduce erosion potential. Higher priority should be given to areas where erosion is encroaching on sea containers or other facilities placed close to the slope. The most significant pad erosion was observed at the north side of the main camp/industrial pad and the Emulsion Plant pad.	Medium	Yes	Construction of the Industrial Pad is scheduled to be completed in 2019. Final grading, capping and compaction will occur at this time.	Complete construction of the Industrial Pad to final grade as per design and technical specifications.	Construction	Summer 2019
9. Emulsion Plant/Road	If erosion occurs in the esker sand material used to construct the emulsion plant road, rockfill should be placed to cap the road and reduce erosion. Placement of gravel road capping may also be beneficial to improve the road surface, particularly over the northern section of the road.	Not Provided	Already Implemented	The road to the emulsion plant was constructed using 600 mm minus esker material, due to the requirement of using "clean" (non-underground sourced) construction materials outside of the contained watershed areas. Capping of the access road with a finer grade produced esker material occured in late 2018.	No	NA	NA
	Consider adding a crushed surface material to the Emulsion Plant and storage area pads if trafficability continues to be an issue.	Medium	No	The Emulsion Plant and storage area pads are outside of the contained watersheds for the Project. Therefore, the choice of construction materials was limited to esker materials. Accordingly, the final grade of the Emulsion Plant pad was sloped to encourage drainage. In addition, a ditch was constructed around half of the pad to further encourage water away from the Plant and garage areas. It is expected that proper snow management in this area prior to freshet 2019 will alleviate many of the trafficability issues observed during 2018.	Ensure correct snow management occurs prior to freshet. Monitor trafficability pre/post freshet. Enhance drainage if required.	Environment/E&I	Prior to Freshet 2019
	It is recommended that the disturbed areas adjacent to the emulsion plant road are regraded so that water does not pond adjacent to the road and thaw the permafrost around and under the road which could lead to settlement.	Medium	Yes	Regrading of natural tundra is difficult, if not impossible to achieve without further thermal disturbance. However, the disturbed areas will be rehabilitated by application of a thermal cap of rock fill material of sufficient thickness to prevent thermal degradation.	Rehabilitate either side of the roadway by replacing the natural peat cover with a thermal cap of rockfill.	Engineering/E&I/Construction	Prior to August 2019
	Culverts should be installed in areas of the emulsion plant road where water was flowing over the road in 2018.	Medium	No	The Emulsion Road was monitored daily for flow across the road, with very minor flows observed for 4 days during the 2018 freshet. AEM will continue to monitor and measure flow rates in this area and culverts will be installed accordingly if required.	Measure flow across road during 2019 freshet and install culvert accordingly.	Environment	Freshet 2019
10. Site Roads/Culverts	Implement a road and culvert monitoring program for site roads, as is done for the AWAR, which is tied to the maintenance program	Medium	Already Implemented	AEM monitors culverts and potential sources of TSS from erosion of site roads at a frequency of daily during freshet, monthly thereafter and following rainfall events.	No	NA	NA
	Consider lowering the lower culvert of Culvert 1 so that water won't pond against the road prior to flowing through the culverts.	Not Provided	Already Implemented	The temporary culverts at Culvert 1 were removed in late 2018, replaced with the design specified diameter culverts and were lowered 0.2 m from the design invert elevations based on field observations from the previous year.	No	NA	NA

	Ponding of water adjacent to roads should be avoided. Disturbed areas from road construction should be recontoured to promote drainage away from the road and consideration should be given to installing culverts if ponding occurs in naturally low areas. This was most notable along the Emulsion Plant and Wesmeg Borrow access roads.	Medium	Already Implemented	Ponding has been noted to be ephemeral in most areas adjaent to roadways and thus permafrost degredation is not a concern when ponds only exist following rainfall events or for the first couple of weeks following freshet. With respect to TSS transport and road washout, AEM agrees that ponded areas should not be allowed to overtop during heavy rainfall.	AEM will continue to monitor roadways to identify locations of long-term ponding and plan to install culverts as needed to reduce ponding and potential for road wash outs.	Environment	Freshet/Open water season 2019
	If the Wesmeg Borrow access road is blocking drainage near Lake B33A that is leading to ponding adjacent to the road, a culvert should be installed to allow drainage so that there isn't permafrost degradation and settlement.	Medium	Yes	Ponding will be tracked at this location and a culvert will be installed if permanent ponding is occuring over the 2019 season.	Monitor ponding and install culvert if needed.	Environment	Freshet/Open water season 2019
11. Operation Landfill	The slopes of the Operation Landfill should be monitored, particularly the northeast corner where water was observed to be ponding downstream and there was some possible sloughing on the slope. Regrading and compacting the slope in this area will reduce the potential for erosion.	Medium	No	The Operation Landfill was built to design specifications, with the floor sloped to encourage drainage to the northeast corner. During the design phase, some ponding in this area was anticipated, particularly during freshet and after rainfall events, as it was acknowledged that it may take some time for water to percolate through the perimeter berm. The designer-approved change in the construction materials of the Landfill (from 600 mm minus waste rock to 600 mm minus esker material) does increase the potential for erosion and/or sloughing of the perimeter berms. However, as the Landfill will be encapsulated within WRSF1 (surrounded by waste rock), it is not felt that additional maintenance on the facility will be of value at this time.	No	NA	NA
12. Other	A coarser rockfill cover should be placed over the pipe berm constructed out of sand on the south side of the effluent water treatment plant to protect against erosion.	Not Provided	Yes	The pipe berm at the EWTP should be covered with a more robust construction material.	Cover pipe berm with 600 mm minus esker/ROM material. Protect HDPE with screened esker/sand material.	Engineering/E&I/Construction	Late summer 2019

Exploration Site

Annual Geotechnical Inspection Recommendation (Golder, 2018)		Priority Level (Golder, 2018)	Recommendation (s) Implemented?	AEM Response to Recommendation	Additional Action(s) Required	Responsible Department(s)	Expected Date of Implementation
1. Landfarm	Minimize the amount of water contained within the exploration landfarm until it is decommissioned and remediated.	Medium	Already Implemented	AEM monitors water levels within the landfarm daily during freshet and following rainfall. Water is pumped to the contaminated snow cell for oil-water separation as needed.	No	NA	NA
2. Camp Pad	Repair surface erosion along south slope of exploration camp pad. Grade surface to reduce channelization of surface water flows and therefore reduce the potential for the erosion to reoccur. In this area, a coarser surfacing layer could be placed to help reduce the potential for future erosion.	Low	No	Decommissioning of the exploration camp facilities is scheduled to begin in 2019. Grading and rehabilitation works will occcur as per closure and reclamation plans.	No	NA	NA
3. Site Roads	The diffuser access road could be regraded to close up the cracks and reduce the potential for future cracking.	Low	No	The diffuser access road sees very limited light vehicle traffic. As this item is of low priority with a limited impact, maintenance work on this road will not be scheduled at this time. The roadway will continue to be monitored and addressed if required for trafficability.	No	NA	NA
	The exploration camp access road should be regraded and consideration given to placing some coarser rockfill on the slopes where there is erosion.	Medium	Yes	The areas of erosion along the exploration access road are observed to be along the shoulder area and could cause safety issues during pullovers. The side slopes should be regraded in these areas.	Regrade side slopes of exploration camp access road in areas where erosion affects shoulder stability.	E&I	Post-Freshet 2019
4. Culverts	The culverts through the exploration camp access road should be cleared of material. Large boulders should be removed from above the culverts to prevent potential damage to the culverts and appropriately sized riprap should be added to the road fills around the culverts for erosion protection where there isn't any.	Medium	Already Implemented	AEM performs culvert inspections weekly prior to freshet, daily during freshet, weekly thereafter during the open water season and following rainfall events. All material (i.e., snow, ice, boulders) is removed when observed. As per AEM's Sediment and Erosion Management Plan, when erosion or sediment entrainment is of concern, rip-rap will be applied to armor the system.	No	NA	NA
5. Fuel Storage	The cracks in the fuel storage pad should be monitored; however they are not considered to be a geotechnical concern.	Low	No	Due to the very minor nature of the cracking observed on the pad, and the low priority of the recommendation, additional monitoring of this area will not be undertaken at this time.	No	NA	NA

AWAR



Annual Geotechnical Inspection Recommendation (Golder, 2018)		Priority Level (Golder, 2018)	Recommendation (s) to be Implemented?	AEM Response to Recommendation	Additional Action(s) Required	Responsible Department(s)	Expected Date of Implementation
1. **Culverts**	Continue to monitor culverts and hydraulic effectiveness to assess if current culverts provide adequate capacity and if any changes are required. Evaluate if any culverts need to be installed at a lower elevation to reduce ponding and downstream erosion.	**Medium**	**Already Implemented**	AEM will continue to inspect AWAR culverts weekly prior to freshet, daily during freshet, weekly thereafter and during rainfall events. Focus is given towards identifying ponding and potential sources of sediment. Culvert effectiveness and ponding as the result of perched culverts are assessed.	**No**	**NA**	**NA**
	Monitor areas that have ponding, but no culverts and consider installing culverts to manage water.	**Medium**	**Already Implemented**	AEM will continue to monitor the AWAR for ponding, track ponded areas and assess the need for culverts.	**No**	**NA**	**NA**
2. **Road Maintenance**	The kilometer markings on the AWAR culverts should be checked and replaced with accurate numbers. At the time of the 2018 site visit, AEM indicated that new markers had been ordered but had not yet arrived.	**Medium**	**Already Implemented**	AEM has received the new marker signs for the culverts and installation will occur in 2019.	Install new markers on AWAR culverts.	E&I	End of July 2019
3. **Inspections**	Conduct inspections and document observations and recommendations as laid out in the Road Management Plan (AEM 2015b). Road inspections were completed and documented in 2018, but documentation indicates that the frequency of the inspections did not quite meet what is laid out in the Road Management Plan.	**High**	**Already Implemented**	Caribou migration affected inspections for approximately three weeks of July 2018, as only essential outdoor work was permitted for much of this duration. Aside from the caribou migration period and severe winter weather conditions, AEM will conduct inspections at the frequency stated within the Road Management Plan.	**No**	**NA**	**NA**

Itivia Bypass

Annual Geotechnical Inspection Recommendation (Golder, 2018)		Priority Level (Golder, 2018)	Recommendation (s) to be Implemented?	AEM Response to Recommendation	Additional Action(s) Required	Responsible Department(s)	Expected Date of Implementation
1. Reporting	The locations of some of the culverts through the Itivia by-pass road do not correlate with the design drawings (Tetra Tech 2017e) due to changes made during construction. The culvert locations should be referenced to the as-built report and drawings during the 2019 annual geotechnical inspection. The as-built report should confirm culvert sizes, locations and invert elevations have been constructed to the design. The as-built report should also confirm that safety berms have been constructed where required based on road fill height and confirm that road slopes have been constructed to design.	**Medium**	**Already Implemented**	The as-built report for the Itivia By-Pass Road was completed by the Design Engineer (Tetra Tech) and submitted to the NWB February 20, 2019.	**No**	**NA**	**NA**
2. Inspection	The section of the road and safety berm that is constructed with esker material may be susceptible to erosion. This should be monitored and maintenance completed as required.	**Low**	**Already Implemented**	The Bypass Road and one of the safety berms were constructed with material approved by the Design Engineer (600 mm minus esker material). Inspections of the roadway for erosion will be conducted as per the Road Management Plan.	**No**	**NA**	**NA**
	Conduct insepctions along Itivia by-pass road, as per the Road Management Plan (AEM 2015b), now that the road is complete.	**Not Provided**	**Already Implemented**	AEM will conduct inspections as per the Road Management Plan	**No**	**NA**	**NA**
3. Water Management	Ponding of water along the road should be monitored and if it is impacting the condition of the road, mitigation measures should be implemented, such as, lowering the culverts or ditching or placing fill to direct water to the culvert inlets.	**Medium**	**Already Implemented**	AEM will conduct inspections and implement mitigation measures as per the Road Management Plan	**No**	**NA**	**NA**
4. Culverts	The culverts should be cleared of all materials prior to freshet.	**High**	**Already Implemented**	As per AEM's Freshet Action Management Plan and Procedure, culverts will be cleared of all material prior to freshet and inspections will be carried out to ensure no blockages during freshet.	**No**	**NA**	**NA**
	The damaged outlets of the culverts through the entrance to the Itivia fuel storage area should be fixed.	**Not Provided**	**No**	Water levels observed within the culvert over 2018 did not pose a concern with respect to being impacted by the damage at the top of the culvert. The culvert will be monitored and if the damage is of concern then repairs will be made.	Monitor the outlet of the culvert to ensure damage does not pose an impact to flow passage.	Environment	2019 Open Water Season
5. Fuel Farm	Cover material should be re-established over the liner that has been exposed on the south containment berm of the Itivia fuel storage facility to protect the liner.	**Medium**	**Yes**	After freshet 2019 is completed, cover material should be raked into place over the liner system (exposed geotextile) to protect the system against exposure to UV radiation and risk of damage.	Schedule maintenance with E&I to occur post freshet 2019. Geotechnical Engineer to inspect maintenance work during and afterwards to ensure liner integrity is not compromised.	Engineering/E&I	Post 2019 Freshet

1 INTRODUCTION

In February 2015, Agnico Eagle Mines Ltd. (Agnico Eagle) was issued the NIRB Project Certificate No. 006, which was subsequently amended in February 2019, for the Meliadine Gold Project, near Rankin Inlet, NU. In April 2016 Agnico Eagle was also issued the Water License No 2AM-MEL1631. In accordance with Conditions 19, 22, and 31, of the Project Certificate, Agnico Eagle has developed a waste rock and quarry monitoring plan to characterize the metal leaching and acid rock drainage (ML/ARD) potential of excavated materials on-site. This report provides the ML/ARD characterization results of samples collected in 2018 from underground development areas at the Meliadine Mine, as well as quarry borrow material used for construction.

The baseline geochemical findings for the site (Golder 2014) found that there was low potential for ARD generation in all of the deposits except the Discovery Zone. Mining activities have not started at Discovery and as a result, 2018 sampling was not expected to find samples with ARD potential. Potential for ARD from Quarry locations was also expected to be low based on characterization studies performed by Golder (2010).

Metal and metalloid (hereafter referred to simply as metal) leaching was also found to have low potential for the areas being mined in 2018, with no management requirements. Arsenic was the element of interest in the deposit, although at concentrations that would not pose a water quality risk. The results from 2018 are presented in context of sampling from 2017 results, as well as in comparison to the range of concentrations predicted from project development studies.

As a result of the project baseline studies establishing that management criteria were not required for the operation, the objective of this characterization program was to confirm the findings from the baseline studies and to ensure that the current management plan is protective of the receiving environment.

2 SAMPLING

2.1 WASTE ROCK

In 2018, 45 samples were collected from waste rock produced as part of underground development activities. The location of the samples are shown in Figure 1 and were taken throughout the mine on levels 125-225 and 275-425. Roughly half of the samples were taken in primary footwall drives, primarily in Meta-Volcanic rocks with a few being taken in secondary footwalls being driven in Meta-Sedimentary Rocks. The other half of samples came from cross-cuts being done to access the ore and were a combination of Meta-Volcanics, Meta-Sediments, and Iron Formations. A few samples were taken in the primary or internal ramps (RP425-450 and RP375-400) along with a few other miscellaneous headings, which were all in Meta-Volcanic Rocks.

Sample collection was performed by the operational geology team as follows:

- Sampling frequency was initially quarterly until the further quarter, when it switched to monthly
- Quarterly sampling to recover 12 samples plus one duplicate
- Monthly sampling to recover 6 samples plus one replicate for a total of 7
- The dominant lithologies encountered in the waste rock were selected by
    - choosing 3 from each of the top three priority headings in the month (i.e. one from each heading)
    - 3 additional samples from the other most active headings each month;
    - The rock type (i.e. volcanic (VOL), sedimentary (SED) or iron formation IF)) were noted with each sample

Each sample was approximately 1kg and representative of the bulk composition of the rock being sampled.

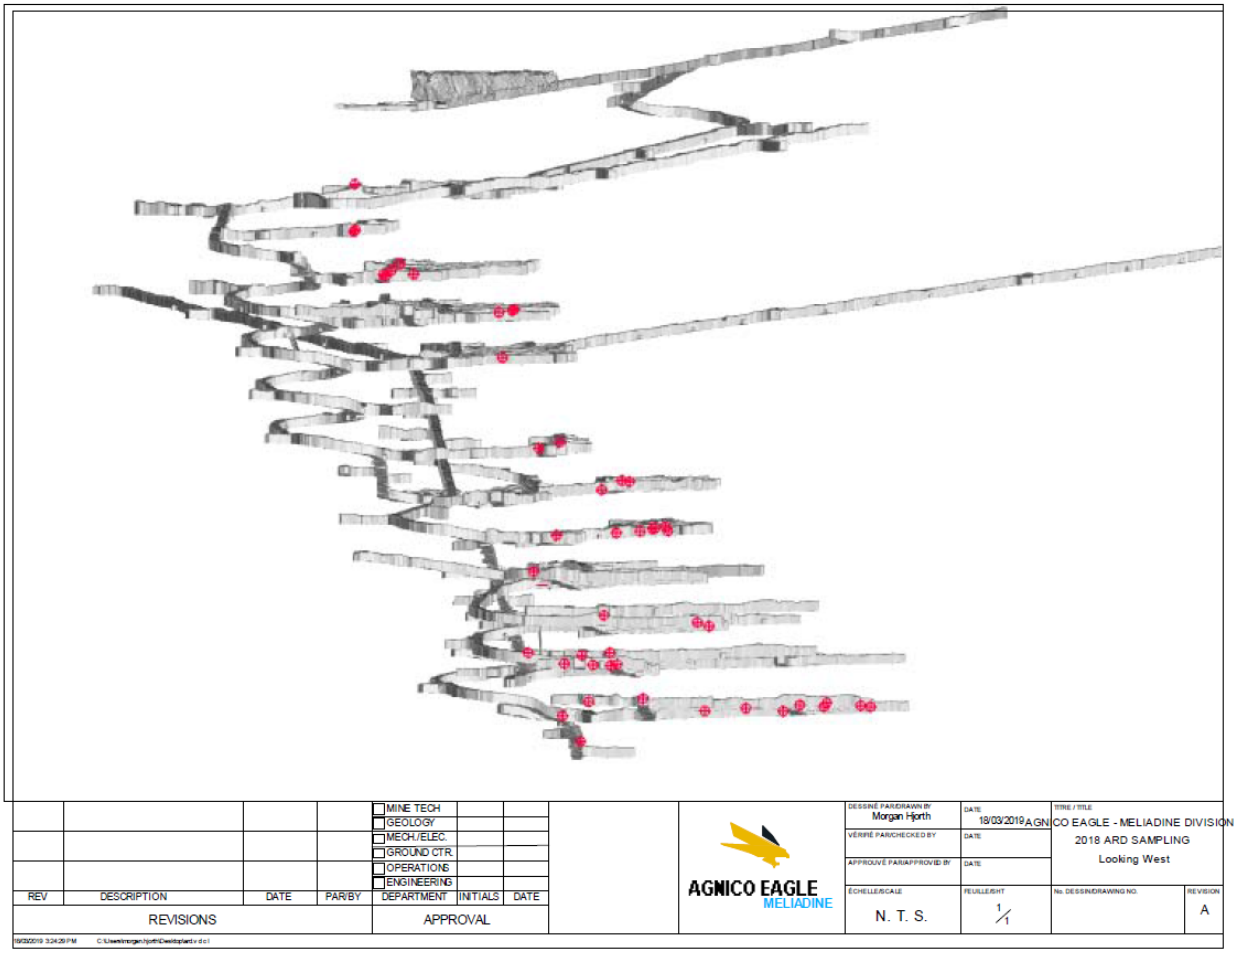

Figure 1: Cross section of underground mine ML/ARD sampling locations.

Note: Sample locations are indicated by red circles.

2.2 SURFACE QUARRIES

In 2018, 30 esker quarry samples were collected for site construction material. The majority of samples in 2018 were from the Meliadine esker (top of Figure 2), with the remainder primarily from Site D (outside of Rankin towards camp, just past the Char River bridge) and the Itivia esker (in Rankin Inlet).

The number of samples collected at each location was based on the estimated volume prior to sampling using a ratio of 8 samples/100,000 tonnes as recommended by MEND (2009). Total volume of the esker/quarry was estimated for bank (in situ) volume and using an estimated bulk density based on typical published values. During excavation of the quarries, typically less material was removed than estimated and the sampling rate was therefore higher than 8/100,000 tonnes.

Depending on whether the quarry location was bedrock or an esker, the material was sampled differently. For bedrock, boreholes were drilled to approximately 5m, with 1 kg of cuttings recovered. In esker material, approximately 1 kg of material was collected by a shovel at each location. The location of quarries is provided in Figure 2.

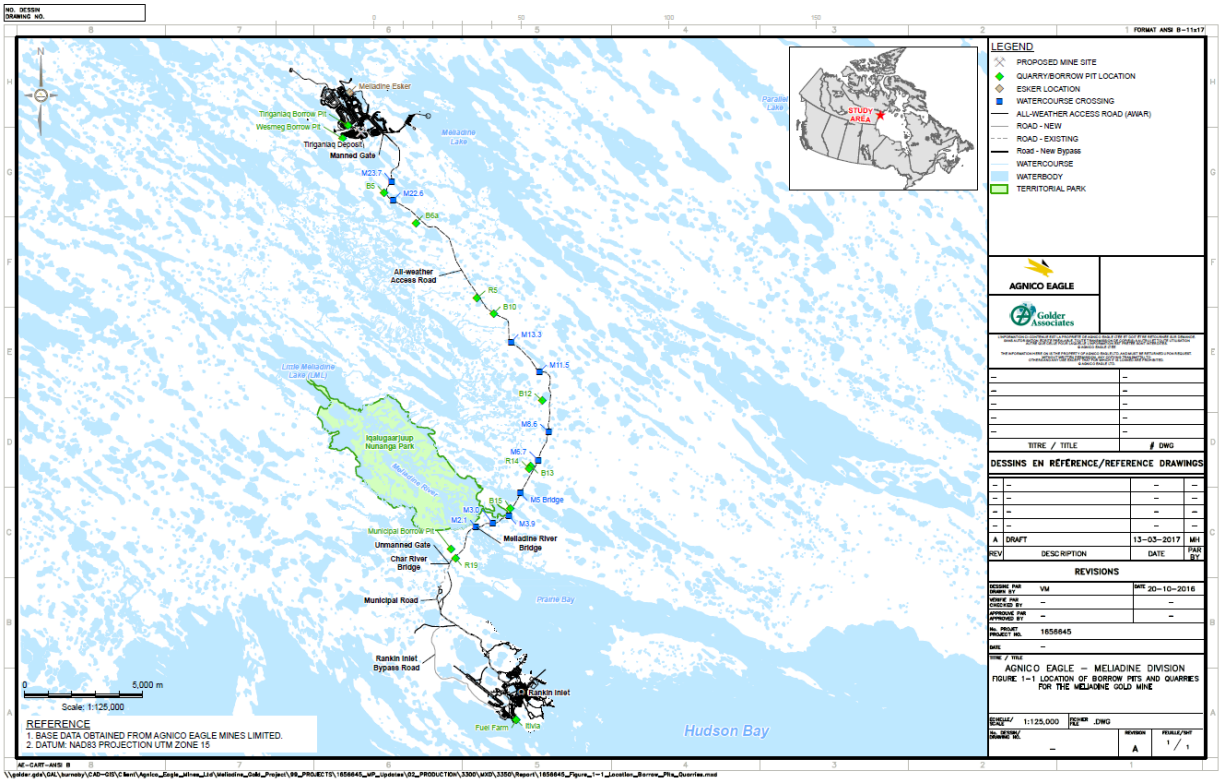

Figure 2: Quarry location map.

3 LABORATORY TESTING

All samples collected were shipped off-site to SGS Lakefield, Ontario, a commercial laboratory with specialization in ML/ARD. Analyses included:

- Acid-base accounting
  - Paste pH
  - Total sulphur (LECO)
  - Sulphate sulphur (HCl leach)
  - Total carbon (LECO)
  - Total inorganic carbon (TIC)
  - Neutralization potential (modified Sobek)
- Element scan by aqua regia digestion and a 31 element ICP-MS finish.

4 RESULTS & DISCUSSION

4.1 MINE DEVELOPMENT WASTE ROCK

4.1.1 ARD POTENTIAL

Neutralization Potential

Neutralization potential (NP) is expected to be primarily provided by calcite and dolomite, with some ankerite (Golder 2014). As a result, carbonate analysis alone would likely be appropriate for determining NP, although both methods were used (i.e. titration and direct carbonate analysis). Complete results are provided in Appendix A, with summary statistics in Table 1.

Golder (2014) indicated that NP from carbonate analysis (NP-Ca) was the more conservative method to determine buffering capacity of the rock and this was used as input into the ARD calculation. The relationship was checked in 2018, and the relationship generally held, especially at low NP values and therefore the continued used of NP-Ca was considered conservative for estimating ARD potential.

Table 1: Summary Statistics for 2018 ARD and Arsenic Results.

Parameter	Units	Min	P5	P25	Median	Mean	P75	P95	Max
Paste pH	s.u.	7.7	8.0	8.3	8.4	8.5	8.8	9.0	9.4
NP	kg $CaCO_3$/t	23	38	72	173	154	222	265	272
AP	kg $CaCO_3$/t	0.62	0.68	1.6	3.8	6.0	6.6	15	43
Sulphur (total)	% S	0.01	0.05	0.09	0.18	0.26	0.29	0.66	1.6
Acid Leachable SO4-S	% S	0.03	0.03	0.05	0.08	0.08	0.10	0.18	0.27
Carbon (total)	% C	0.15	0.51	1.3	2.2	2.1	2.8	4.0	4.2
Carbonate (CO_3)	% CO_3	0.49	2.0	4.5	10	9.4	13	18	20
NP-Ca	kg $CaCO_3$/t	8.2	34	75	168	157	220	307	325
NP-Ca/AP	ratio	1.8	5.71	19	32	26	71	228	246
Arsenic	mg/kg	2.8	4.7	15	56	382	130	1240	6000

Notes: P stands for percentile (e.g. P5 equals 5th percentile); NP-Ca is stands for NP by carbonate content.

Acid Potential

Project prediction studies indicated that the main sulphide minerals in the waste rock was pyrite, but also with arsenopyrite and lesser pyrrhotite, and chalcopyrite (Golder 2014). As a result, the main consideration for acid potential (AP) is the presence of sulphide minerals at Meliadine.

Project prediction studies were confirmed in 2018 sampling with acid-base accounting testing showing that sulphur is primarily present in the sulphide form (Table 1 summary, full results in Appendix A). Sulphur ranged from below detection 0.01% to a maximum of 1.6%, with a median of 0.18%.

ARD Assessment

The potential for ARD was assessed using NP-Ca/AP ratios (or neutralization potential ratios, NPR). AP was calculated from total sulphur. Ratios below 2 were used to indicate potential for ARD (PAG or potentially ARD generating), whereas ratios above 2 indicate low potential for ARD (non-PAG).

The classification of all Meliadine waste rock samples from underground since testing began in 2017 are provided in Figure 3 and a summary of ratios are provided in Table 1. As predicted by Golder (2014), the majority of operational muck samples collected to date were non-PAG. Samples from 2017 have also been included for ease of comparison to historical results.

The one exception was a sedimentary sample with an NPR of 1.8. This sample is not considered a risk as there is excess buffering in all other samples collected and it is only marginally below the non-PAG criterion. Given the carbonate mineralogy of the Meliadine samples, the threshold for a sample to produce ARD is likely closer to an NPR of one and this sample is unlikely to produce ARD even without the buffering of any other samples.

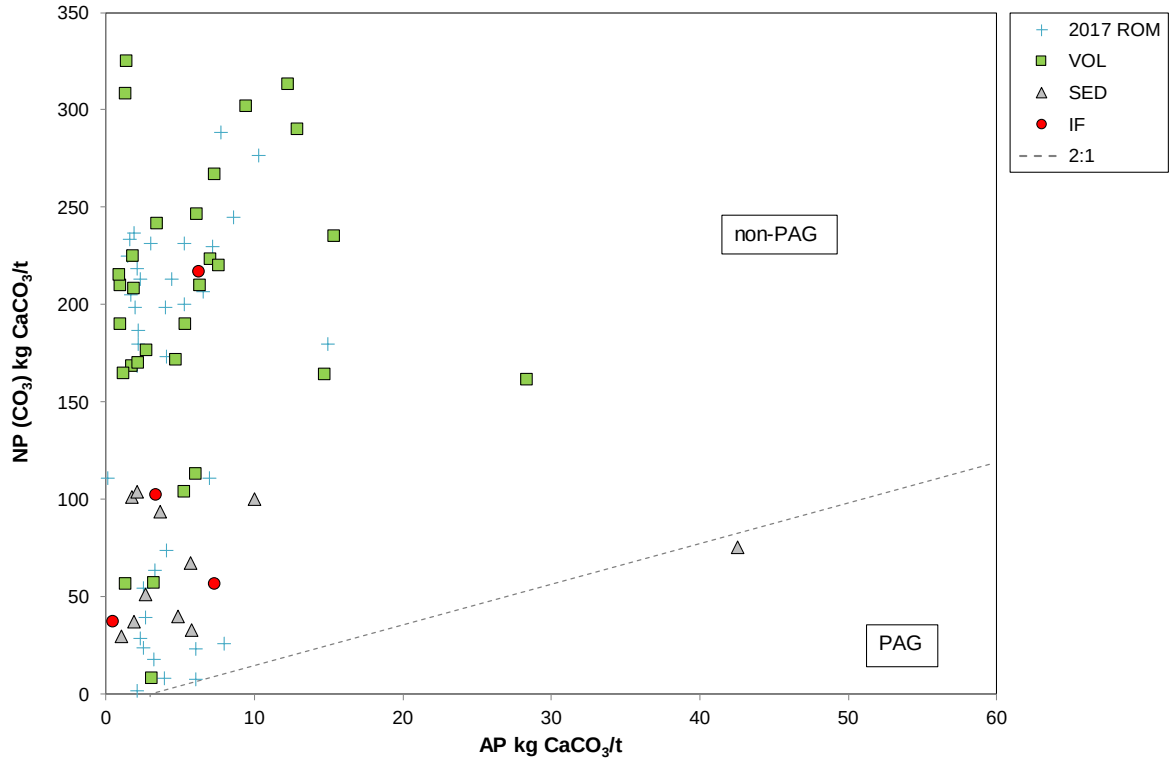

Figure 3: ARD classification of Meliadine Underground Waste Rock Samples.

Notes: ROM stands for run of mine; VOL for volcanics; SED for sedimentary/greywacke; IF for iron formation.

4.1.2 METAL LEACHING

Metal leaching was predicted by Golder (2014) to be low enough that management of waste rock to inhibit leaching was not required. However, based on project screening studies, arsenic was determined to be the main element of interested and analysis of this element (and all regulated elements) were part of operational monitoring since mining began. A statistical summary for arsenic is provided in Table 1, with complete element composition results provided in Appendix B.

To ensure arsenic concentrations were within project predictions, results have been compiled and compared against average and maximum arsenic concentrations reported by Golder (2014). As

shown in Figure 4, solid phase arsenic concentrations mainly fall within or below the average concentration, with no samples exceeding the maximum concentration reported by Golder (2014).

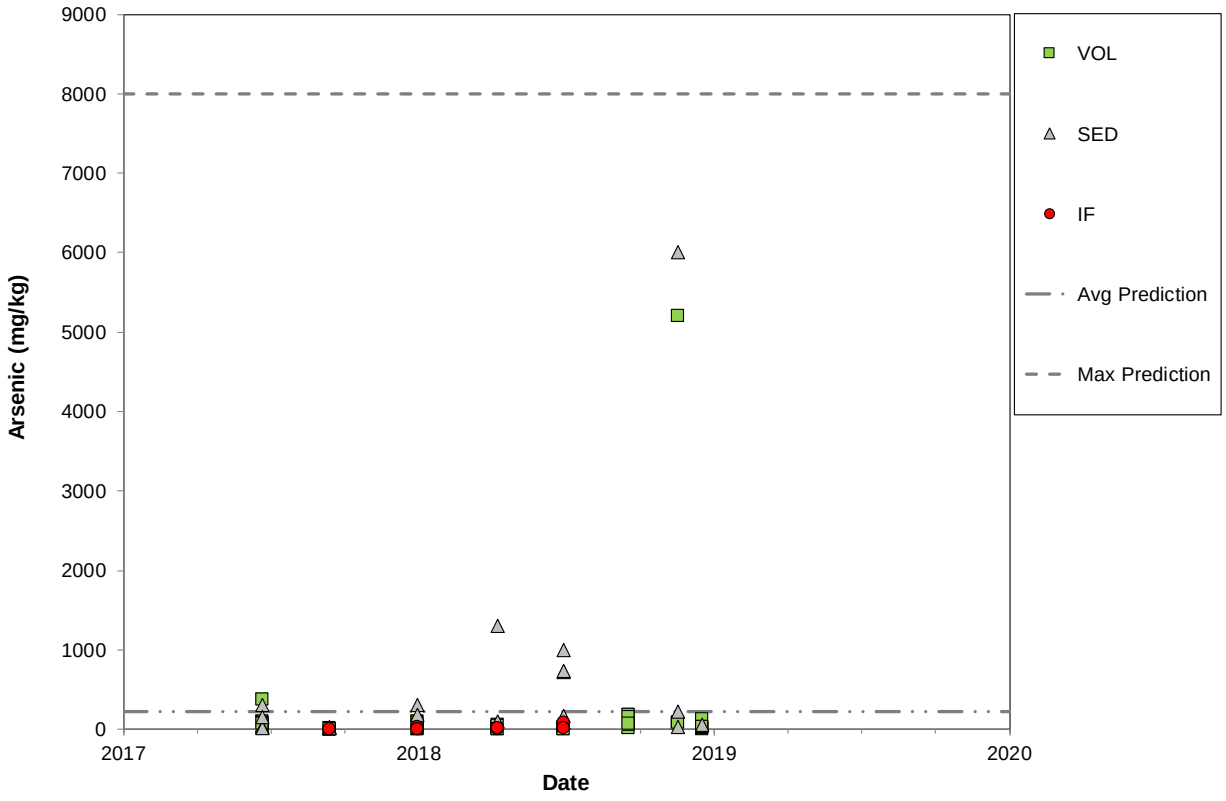

Figure 4: Arsenic concentrations in waste rock compared to project prediction studies.

4.2 Quarry Material

4.2.1 ARD Potential

The potential for ARD from Quarry samples collected in 2018 was assessed by the same approach described above for waste rock in Section 4.1, whereby NP was provided by carbonate (NP-Ca) and AP was estimated based on total sulphur.

Complete results are provided in Appendix C with summary statistics provided in Table 2. NP-Ca ranged from 2 to 44 kg $CaCO_3$/t, with a median of 9.2 kg $CaCO_3$/t. Total sulphur ranged from near detection limits of 0.01% to a 0.1%, with a median of 0.02%. These are relatively low sulphur numbers as typically any rock with less than 0.1% sulphur will not generate acidity regardless of the carbonate content as other rock components such as alkaline silicates (e.g. feldspars) can neutralize the small amount of acid produced.

The potential for quarry material to produce ARD was based on NPR ratios, but also a sulphur limit of 0.1%, meaning that any samples with 0.1% or less sulphur would be non-PAG regardless of the NPR ratio. Based on the two criteria, none of the quarry samples collected were PAG. The 0.1% sulphur criterion affected 4 out of 30 samples. A statistical summary is provided in Table 2 and the classification of all samples collected since operations began are shown in Figure 5.

Table 2: Summary Statistics for Quarry Rock Samples Collected in 2018.

Parameter	Units	Min	P5	P25	Median	Mean	P75	P95	Max
Paste pH	s.u.	5.6	6.1	7.0	8.6	8.1	9.1	9.6	9.7
NP	kg $CaCO_3$/t	2.0	3.1	5.5	9.2	10	11	20	44
AP	kg $CaCO_3$/t	0.62	0.62	0.6	0.6	0.7	0.6	1.3	1.6
Sulphur (total)	% S	0.01	0.01	0.01	0.02	0.03	0.04	0.07	0.1
Acid Leachable SO4-S	% S	0.02	0.02	0.02	0.03	0.03	0.04	0.04	0.1
Carbon (total)	% C	0.06	0.06	0.08	0.16	0.44	0.60	1.5	2.2
Carbonate (CO3)	% CO_3	0.04	0.04	0.08	0.14	0.26	0.29	0.82	1.6
NP-Ca	kg $CaCO_3$/t	0.58	0.67	1.3	2.3	4.3	4.9	14	27
NP-Ca/AP	ratio	0.48	1.5	2.3	3.3	5.7	5.9	17	36
Arsenic	mg/kg	0.58	1.3	3.4	5.3	7.7	7.8	17	58

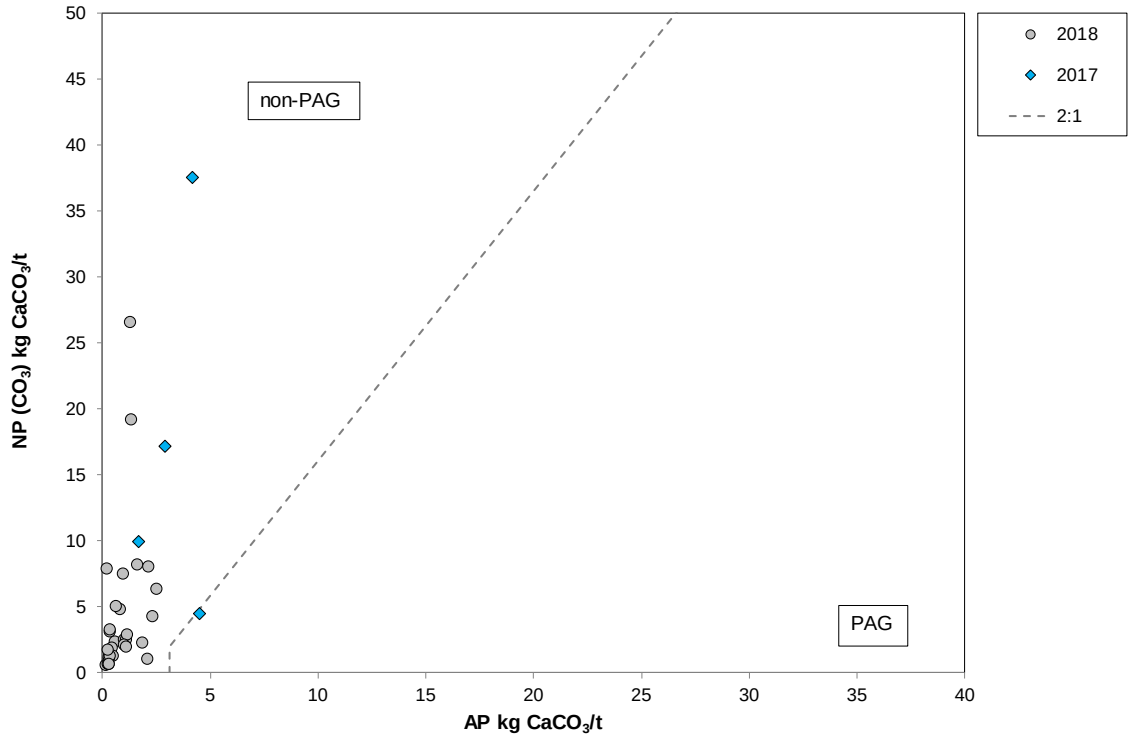

Figure 5: Quarry ARD Assessment.

Note: the vertical dashed line represents 0.1% S threshold.

4.2.2 METAL LEACHING

The same approach taken for waste rock was applied to quarry samples in terms of comparing against project prediction studies. All regulated elements were analysed in solid samples are included in Appendix D. Given the general presence of arsenic in the waste rock and background concentrations in the area, results for this element are summarized below.

Arsenic concentrations ranged from a minimum of 0.58 mg/kg to a maximum of 58 mg/kg, with a median of 5.3 mg/kg. These values are relatively low compared to waste rock and were within project prediction studies as the maximum value reported by Golder (2010) was 121 mg/kg. A statistical summary is provided in Table 2 and all results since sampling began in 2017 are provided in Appendix D.

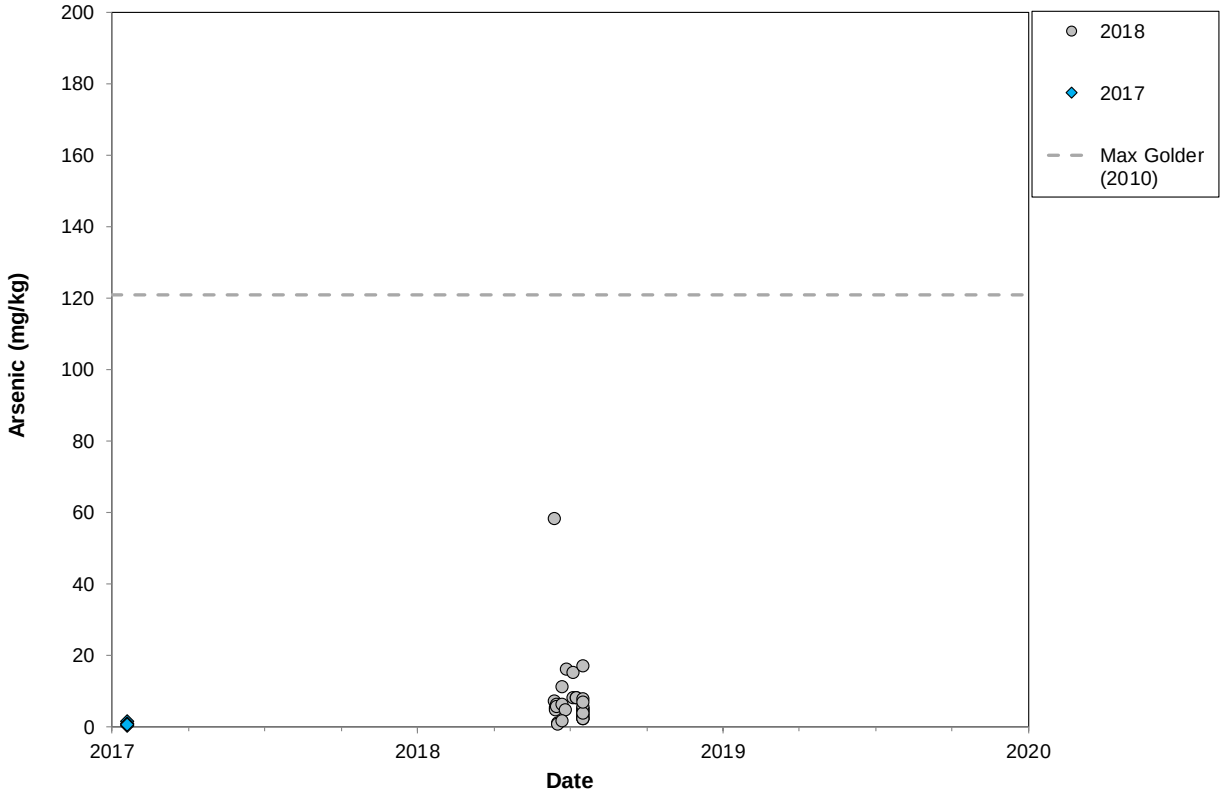

Figure 6: Solid Phase Quarry Arsenic Concentrations.

5 CONCLUSIONS

Based on geochemical characterization results obtained to date for the waste rock and quarry samples, there is low risk for ARD or metal leaching from the materials. Results are within project prediction studies for the project. Sampling will continue in 2019, with results reviewed internally as soon as they are available and provided with the 2019 annual report.

Project : PO#OL-664693

LR Report : **CA15390-DEC18**

*NP (Neutralization Potential)

$$= \frac{50 \times (N \text{ of HCL} \times \text{Total HCL added} - N \text{ NaOH} \times \text{NaOH added})}{\text{Weight of Sample}}$$

*AP (Acid Potential) = % Sulphide Sulphur x 31.25
*Net NP (Net Neutralization Potential) = NP-AP
NP/AP Ratio = NP/AP
*Results expressed as tonnes CaCO3 equivalent/1000 tonnes of material
Samples with a % Sulphide value of <0.02 will be calculated using a 0.02 value.

GLOSSARY

PM: Particulate matter

SVOC (PCDD/F): Dioxins and furans

ME: Metals

O_2: Oxygen

CO_2: Carbon dioxide

CO: Carbone monoxide

NO_X: Nitrogen oxide

ACFM: Actual cubic feet per minute

ECCC: Environment and Climate Change Canada

USEPA: United Stated Environmental Protection Agency

QA/QC: Quality Assurance / Quality Control

ΔP: Differential pressure read at the stack

ΔH: Differential pressure read at the control unit

DL: Detection Limit

SUMMARY

Consulair was mandated by Agnico Eagle Mines, Meliadine Division, to sample the atmospheric emissions at the outlet of an incinerator of its plant located near Rankin Inlet, Nunavut.

The objectives of the characterization of atmospheric emissions were to:

- Evaluate the physical characteristics of the gas flow in the stack;
- Evaluate the concentration and the emission rate of the particulate matter (P), Metals (ME) and Hydrogen chloride (HCl);
- Demonstrate the performance of the incinerator to meet the standards for mercury (Hg) and dioxins and furans (PCDD/F);
- Ensure that QA/QC of Consulair is respected throughout the stack sampling program.

For this project, the applicable standards are shown below with the tests results. The applicable standards for dioxins and furans (PCDD/F) were met for all tests, as well as the applicable standard for mercury (Hg). The standards come from the "Environmental Guideline for the Burning and Incineration of Solid Waste" emitted by the Department of Environment of the Government of Nunavut base on the Canadian Council of Ministers of the Environment (CCME) Canada - Wide Standards for Dioxins and Furans and Mercury Emissions.

The government of Nunavut presented a guideline document in October 2010, which was revised in January 2012, for the burning and incineration of solid waste. The document presented two criteria for air emissions which are applicable in the current project. A standard for Dioxins and Furans is stated at 80 pg I-TEQ/m^3 and another standard for mercury is stated at 20 µg/Rm^3. The reference conditions are stated at 101.3 kPa and 25°C and both standards are corrected to 11% O_2.

APPLICABLE STANDARDS		
CONTAMINANTS	**TEST RESULTS**	**STANDARDS**
MERCURY (Hg)	0.23 µg / Rm^3 @ 11 % v/v O_2	20 µg / Rm^3 @ 11 % v/v O_2
DIOXINS AND FURANS (PCDD/F)	0.042 ng / Rm^3 @ 11 % v/v O_2	0.08 ng TEQ / Rm^3 @ 11 % v/v O_2

R: Reference conditions 25 °C and 101.3 kPa on a dry basis.

SUMMARY

INORGANIC SAMPLING TRAIN

NITROGEN OXIDES (NO_X) as NO_2	
NO_X (ppmvd) - average	53
NO_X as equivalent NO_2 (mg/Rm^3)	100
NO_X (kg/h)	0.65
SULPHUR DIOXIDE (SO_2)	
SO_2 (ppmvd) - average	0.2
SO_2 (mg/Rm^3)	0.6
SO_2 (kg/h)	0.004
R: Reference conditions 25 °C, 101.3 kPa on a dry basis.	

The sampling was performed in compliance with the rules of the requirements of the Report No. EPS 3/UP/2, including methods recommended by "Environment and Climate Change Canada" (ECCC) of the Government of Canada inside "Environment Canada, The National Incinerator Testing and Evaluation Program: Air Pollution Control Technology". Report No. EPS 3/UP/2, Ottawa, 1986.

1 INTRODUCTION

Consulair was mandated by Agnico Eagle Mines, Meliadine Division (Nu), to demonstrate the performance of the incinerator to meet the standards for mercury (Hg) and dioxins and furans (PCDD/F).

1.1 Sampling scope

The objectives of the characterization of atmospheric emissions were to:

- Evaluate the physical characteristics of the gas flow in the stack;
- Evaluate the concentration and the emission rate of particulate matter (P), Metals (ME) and Hydrogen chloride (HCl);
- Demonstrate the performance of the incinerator to meet the standards for mercury (Hg) and dioxins and furans (PCDD/F);
- Ensure that QA/QC of Consulair is respected throughout the stack sampling program.

The study included sources and pollutants referred in the following table.

Table 1-1 – OVERALL TEST MATRIX

SOURCE	POLLUTANTS	SAMPLING METHODS
Incinerator outlet	Particulate matter (PM)	EPS 1/RM/8 EC
	Hydrogen chloride (HCl)	EPS 1/RM/1 EC
	Metals	USEPA 29
	SVOC (PCDD/F)	EPS 1/RM/2 EC

2 SAMPLING TEAM AND PARTICIPANT

The interveners of this testing program are listed in Table 2-1 and 2-2. The analysis laboratory used is defined in Table 2-3.

3 SAMPLING

3.1 Process operation

A representative of the Agnico Eagle mines company had the responsibility to monitor the operating conditions to ensure the representativeness of the sampling. In order to perform the sampling program under representative conditions, a tight liaison was maintained with the operators during testing.

Process operating conditions of the incinerator were under Agnico-Eagle's responsibility. The operating conditions were maintained stable throughout each days of the test program.

3.2 Source description

The number of measuring points in the stack was determined in accordance with the requirements of Environment Canada's EPS 1/RM/8 sampling method entitled: "Reference methods for source testing: measurement of releases of particulate from stationary sources".

Stacks characteristics are described in the following table.

Table 3-1 – SAMPLED SITE CHARACTERISTICS

SOURCE	DIMENSION(S) Stack (m)	DIAMETER NUMBER)		NUMBER OF SAMPLING POINTS	
		A_D	B_D	Number of port used and sampling points	Total
Incinerator outlet	0.826	5.0	2.0	2 x 6	12

3.3 Sampling methodology

Sampling methods used in this project are methods approved and recommended by known organisms such as the United States Environmental Protection Agency (US EPA) and Environment Canada (EC).

The following table shows the sampling methods that were used during testing.

Table 3-2 – SAMPLING METHODS

PARAMETERS	METHODS	SAMPLING DURATION (min)
Manual sampling methods		
Temperature	Thermometer or thermocouple	With isokinetic value
Gas flow	SPE 1/RM/8, method B – Environment Canada	With isokinetic value
O_2, CO_2, CO	SPE 1/RM/8, method C – Environment Canada	With isokinetic value
Moisture content	SPE 1/RM/8, method D – Environment Canada	With isokinetic value
Particulate matter (PM)	SPE 1/RM/8, method E – Environment Canada	120 / 170 / 180
HCl	SPE 1/RM/1 – Environment Canada	
Metals	USEPA, CFR 40, Part 60, Method 29	
SVOC (PCDD/F)	SPE 1/RM/2 – Environment Canada	240 / 150 / 180
Instrumental sampling method		
NO_X	USEPA, CFR 40, Part 60, Method 7E	60
SO_2	USEPA, CFR 40, Part 60, Method 6C	60

The distribution of parameters within the sampling train is presented in the following table.

Table 3-3 – DISTRIBUTION OF PARAMETERS FOR EACH SAMPLING SYSTEM

SAMPLING TRAIN	PARAMETERS
Metals & Particulate matter & HCl	PM & Metals & HCl
SVOC	PCDD/F

3.4 Temperature, moisture content and flowrate

Gas temperature, flowrate, velocity and moisture content will be measured at the sampling sites according to "Reference methods for source testing: measurement of releases of particulate from stationary sources". Methods B and D, Environment Canada, December 1993, EPS 1/RM/8.

3.5 Isokinetic sampling

Isokinetic sampling allows to collect particles in the sampling nozzle at the same velocity as the gas stack velocity. In non-isokinetic conditions, if the sampling velocity is inferior than the gas stack velocity, more large particles would be collected resulting in an overestimation of the true mass concentration. On the opposite, if the sampling velocity is superior than the gas stack velocity, less large particles would be collected resulting in underestimation of the true mass concentration. In either case, the sample collected would not be an accurate reflection of the gas stack stream.

The following table presents a test acceptance criteria according to the methods (sampling systems) used.

Table 3-4 – SAMPLING ACEPTANCE CRITERIA

PARAMETERS	METHOD	ACCEPTANCE CRITERIA
Particulate Matter	SPE 1/RM/8	• Isokinetic rate comprised between 90 % and 110 % • Less than 10% of the sampled points out of the 90 % to 110 % range
Metals	Method 29 from USEPA	
SVOC	SPE 1/RM/2	

3.5.1 Particulate matter (PM), metals & HCl

Particulate matter (PM) and metals (Al, Sb, Ag, As, Ba, Be, Bi, B, Cd, Ca, Cr, Co, Cu, Sn, Fe, Li, Mg, Mn, Mo, Ni, Pb, K, Se, Na, Ti, V, Zn, Sr, Tl, Si (Silicium soluble), Hg) were sampled in accordance with the requirements of Environment Canada EPS 1/RM/8 sampling method entitled: "Reference methods for source testing: measurement of releases of particulate from stationary sources". This method was combined with USEPA method 29 entitled “Metals emissions from stationary sources" in order to allow for metals sampling (including Hg). HCl was analyzed in the first impinger of that sampling train.

Table 3-5 – MAIN COMPONENTS OF THE PM/HCl/METALS SAMPLING SYSTEM

SAMPLING PROBE	SAMPLING TRAIN	CONTROL UNIT
• Quartz nozzle; • Quartz probe; • S type Pitot tube for the gas velocity attached to the sample probe; • Thermocouple for temperature attached to the sample probe.	• A 0.3 µm porosity pre-weighted quartz filter mounted in a Pyrex filter holder and placed in a heated oven to avoid moisture condensation; • Seven impingers placed in series and containing: ○ # 1: 100 mL H_2O; ○ # 2 and # 3: 100 mL HNO_3 (5%) / H_2O_2 (10%) solution; ○ # 4: empty; ○ # 5 and # 6: 100 mL $KMnO_4$ (4%) / H_2SO_4 (10%) solution; ○ # 7: silica gel; • Impingers placed in an ice bath to condense all the flue gas moisture.	• Sampling cord that connects the train to the sampling console; • Sampling console with oil manometer, a dry gas meter, an orifice, a temperature reader and temperature controllers; • Diaphragm vacuum pump.

3.5.2 Semivolatile organic compounds (SVOC) (PCDD/DF)

Semi Volatile Organic Compounds (SVOC) are defined as organic compounds with boiling points greater than 100 °C. This class of compounds includes PCDD (PolyChlorinated Dibenzo p Dioxins), PCDF (PolyChlorinated DibenzoFurans),

SVOCs (PCDD/F) were sampled in accordance with the requirements of Environment Canada EPS 1/RM/2 sampling method entitled: " Reference Method for Source Testing: Measurement of Releases of Selected Semi-Volatile Organic Compounds from Stationary Sources ". For this project, SVOCs included polychlorinated dibenzo-p-dioxins (PCDD) and polychlorinated dibenzofurans (PCDF). A minimal volume of at least 3.0 Rm^3 was sampled during each run.

For one series of three SVOC tests, a blank train was taken to the stack sampling site. A volume of ambient air equal to the sum of all leak check volumes during the SVOC test was pumped through the blank train, according to the requirements of reference method EPS 1/RM/2.

The following table shows the various components of the sampling system for PCDD/F.

Table 3-6 – MAIN COMPONENTS OF A SVOC SAMPLING SYSTEM

SAMPLING PROBE	SAMPLING TRAIN	CONTROL UNIT

• Glass nozzle of a precisely measured diameter to allow isokinetic sampling;
• Glass heated probe to avoid moisture condensation;
• Probe is fastened to an "S" type Pitot tube for gas velocity measurement and to a thermocouple for temperature measurement.
	• A 0.3 µm porosity pre-weighted fiber glass filter mounted on an accurate holder and placed in a heated oven to avoid moisture condensation;
	• Condenser;
	• XAD-2 resin cartridge;
	• Condensate trap;
	• Three impingers placed in series and containing:
	  ○ # 1: 100 mL ethylene glycol;
	  ○ # 2: empty;
	  ○ # 3: silica gel;
	• Impingers placed in an ice bath to condense all the flue gas moisture.
		• Sampling cord that connects the train to the sampling console;
		• Sampling console with oil manometer, a dry gas meter, an orifice, a temperature reader and temperature controllers;
		• Diaphragm vaccum pump.

3.6 Gaseous parameters (O_2, CO_2, CO, SO_2 & NO_X)

One CEM (Continuous Emission Monitoring) systems was used to determine the concentration of O_2, CO_2, CO, SO_2 & NO_X. The CEM system includes a gas extraction system, one analyzer and a data acquisition system. The moisture-free gas was analysed for O_2, CO_2, CO, SO_2 & NO_X with an analyzer as described in the following table.

Graphics of continuous measurements of gas are presented in Appendix 2 of the report.

Table 3-7 – GAS ANALYZER

ANALYZER	O_2/CO_2	CO	SO_2	NO_X
Method	USEPA 3A	USEPA 10	USEPA 6C	USEPA 7E
Brand	Horiba	Horiba	Horiba	Horiba

	2018-09-29	16:14-19:14	PM/Metal/HCl # 3

3.8 LAWS AND REGULATIONS

The government of Nunavut presented a guideline document in October 2010, which was revised in January 2012, for the burning and incineration of solid waste. The following emission standards apply to existing, new or expanding solid waste incinerators operating in Nunavut and have been adopted from the Canadian Council of Ministers of the Environment (CCME) Canada - Wide Standards for Dioxins and Furans and Mercury Emissions. The document presented two criteria for air emission which are applicable in the current project. A standard for Dioxins and Furans is stated at 80 pg I-TEQ/m^3 and another standard for mercury is stated at 20 µg/Rm^3. The R conditions are stated at 101.3 kPa and 25°C. Both standards are corrected to 11% O_2.

4 QUALITY CONTROL PROCEDURES (QA/QC)

The quality insurance program and control at Consulair has several elements to validate the methodologies used during sampling. The main points are detailed within this section.

4.1 QA/QC – PRE-TEST

4.1.1 Equipment, instruments and reagents

The sampling train glassware and sample containers were cleaned and checked according to the applicable reference methods.

The instruments used were subject of regular maintenance and are calibrated for less than a year. The calibration constants of the equipment used are shown in Tables 4-1 to 4-3. Calibration certificates of equipment are presented in Appendix 3 of the report.

The gas standards used for calibration of the analyzer were valid at the time of use considering the retention periods imposed by the supplier. The standard gases are certified to ± 2% by the supplier.

4.1.2 Field forms

The forms that present field data for the target parameters are shown in Appendix 5.

4.2 Sample tracking

A clean room inside the incinerator building was used for the assembly and the different stages of recovery of sampling trains. Recovery of samples was performed according to the procedures recommended by the methods.

The samples were collected in suitable containers as specified by the methods. All samples were kept cool during the sampling period and until the delivery of samples to analytical laboratories. Consulair used an identification system for the samples that allowed tracking the origin easily by a unique code coupled to a lookup table. Each sample number includes the date, test number, the precise location of the sampling, the nature and destination (analysis, archiving). This information is indicated on the chain of custody listing and the information is available on the analysis reports.

4.3 Validation criteria

Consulair ensured that each step of the air emission characterization program (including QA / QC program) will achieve the defined objectives, while respecting the deadline set by the customer.

4.3.1 Analytical laboratory

The particulate samples analysis was done in the laboratory of Consulair. This laboratory is accredited by the *Centre d'Expertise en Analyse Environnementale du Québec* (CEAEQ) for particulate matter (domain 400 of the air chemical section). The metals samples were analysed by Maxxam's laboratory, which is accredited by the *Centre d'Expertise en Analyse Environnementale du Québec* (CEAEQ) for metallic analysis (domain 404 of the air chemical section). The PCDD/F samples were analysed by AGAT's laboratory, which is accredited by the *Centre d'Expertise en Analyse Environnementale du Québec* (CEAEQ) for PCDD/F analysis (domain 510 of the air chemical section).

The analytical reports have been signed by a chemist and are presented in appendix 4. The laboratory also made available, in its report, the QA/QC program specific to the analysed contaminants.

4.3.2 Validation criteria – Particulate matter / Metals / HCl (PM/ME/HCl)

The following tables show the validation criteria of the methodology used.

Table 4-1 – QA/QC METHODOLOGY – PM/METALS/HCl

SPE 1/RM/8 METHODOLOGICAL INFORMATION				
TEST	ME-1	ME-2	ME-3	**CRITERIA**
CYCLONIC FLOW	0			≤ 15°

R: Reference conditions at 101.3 kPa et 25°C, and dry basis.				

The sampling time for the second run of SVOC is under the 180 minutes limit of the method because of a process malfunction and the sampling had to be stopped. However, since the sampling volume for this test run is higher than the 3.0 m^3 limit of the method, this should have no impact on the result.

5 RESULTS

The reference values are reported at a temperature of 25°C and an atmospheric pressure of 101.3 kPa, on a dry basis.

For the inorganic results, a laboratory analysis value preceded of "<" means that the laboratory result is less than the detection limit reported (LDR) and represents a maximum result. In this case, the detection limit reported (LDR) is the value used.

The PCDD / F result tables include all toxic congeners (17) calculated with TEF (Toxic Equivalency Factor). The term "toxic equivalency (TEQ)" is the sum of the 17 toxic congeners calculated according to the TEF and when a congener was not detected by the laboratory analysis, it was replaced by "zero".

Unless otherwise indicated, the averages indicated in the tables below are the average of all tests carried out to the same source for the same operating condition.

Computer compiled data is presented in Appendix 1.

6 CONCLUSION

According to the sampling methods and procedures combined with a rigorous quality control, the results of concentrations and / or emission rates presented in this report are valid and representative of the process operation conditions sampled for period test results.

The final results obtained are valid and representative of the operating conditions during the tests.

The sampling was made in compliance with the rules of the requirements of the Report No. EPS 3/UP/2, including methods recommended by “Environment and Climate Change Canada” (ECCC) of the Government of Canada inside “Environment Canada, The National Incinerator Testing and Evaluation Program: Air Pollution Control Technology”. Report No. EPS 3/UP/2, Ottawa, 1986.

Remarques:

Les laboratoires Maxxam sont certifiés ISO/IEC 17025:2005 pour certains paramètres précis des portées d'accréditation. Sauf indication contraire, les méthodes d'analyses utilisées par Maxxam s'inspirent des méthodes de référence d'organismes provinciaux, fédéraux et américains, tels que le CCME, le MDDELCC, l'EPA et l'APHA.

CERTIFICAT D'ANALYSES

 # DE DOSSIER MAXXAM: B847715
Reçu: 2018/10/19, 12:30

Toutes les analyses présentées ont été réalisées conformément aux procédures et aux pratiques relatives à la méthodologie, à l'assurance qualité et au contrôle de la qualité généralement appliqués par les employés de Maxxam (sauf s'il en a été convenu autrement par écrit entre le client et Maxxam). Toutes les données de laboratoire rencontrent les contrôles statistiques et respectent tous les critères de CQ et les critères de performance des méthodes, sauf s'il en a été signalé autrement. Tous les blancs de méthode sont rapportés, toutefois, les données des échantillons correspondants ne sont pas corrigées pour la valeur du blanc, sauf indication contraire. Le cas échéant, sauf indication contraire, l'incertitude de mesure n'a pas été prise en considération lors de la déclaration de la conformité à la norme de référence.

Les responsabilités de Maxxam sont restreintes au coût réel de l'analyse, sauf s'il en a été convenu autrement par écrit. Il n'existe aucune autre garantie, explicite ou implicite. Le client a fait appel à Maxxam pour l'analyse de ses échantillons conformément aux méthodes de référence mentionnées dans ce rapport. L'interprétation et l'utilisation des résultats sont sous l'entière responsabilité du client et ne font pas partie des services offerts par Maxxam, sauf si convenu autrement par écrit. Maxxam ne peut pas garantir l'exactitude des résultats qui dépendent des renseignements fournis par le client ou son représentant.

Les résultats des échantillons solides, sauf les biotes, sont rapportés en fonction de la masse sèche, sauf indication contraire. Les analyses organiques ne sont pas corrigées en fonction de la récupération, sauf pour les méthodes de dilution isotopique.
Les résultats s'appliquent seulement aux échantillons analysés. Si l'échantillonnage n'est pas effectué par Maxxam, les résultats se rapportent aux échantillons fournis pour analyse.
Le présent rapport ne doit pas être reproduit, sinon dans son intégralité, sans le consentement écrit du laboratoire.
Lorsque la méthode de référence comprend un suffixe « m », cela signifie que la méthode d'analyse du laboratoire contient des modifications validées et appliquées afin d'améliorer la performance de la méthode de référence.
Notez: Les données brutes sont utilisées pour le calcul du RPD (% d'écart relatif). L'arrondissement des résultats finaux peut expliquer la variation apparente.

Note : Les paramètres inclus dans le présent certificat sont accrédités par le MDDELCC, à moins d'indication contraire.

REMARQUES GÉNÉRALES

MÉTAUX (SOLUTION BARBOTEUR)

Les limites de détection indiquées sont modifiées en fonction du volume d'échantillon reçu.

MÉTAUX (TRAIN)

Les limites de détections indiquées sont multipliées par les facteurs de dilution utilisés pour l'analyse des échantillons.
Les limites de détection indiquées sont modifiées en fonction du volume d'échantillon reçu.

Les résultats ne se rapportent qu'aux échantillons soumis pour analyse

LDR = Limite de détection rapportée

MRC: Un échantillon de concentration connue préparé dans des conditions rigoureuses par un organisme externe. Utilisé pour vérifier la justesse de la méthode.

Blanc fortifié: Un blanc, d'une matrice exempte de contaminants, auquel a été ajouté une quantité connue d'analyte provenant généralement d'une deuxième source. Utilisé pour évaluer la précision de la méthode.

Blanc de méthode: Une partie aliquote de matrice pure soumise au même processus analytique que les échantillons, du prétraitement au dosage. Sert à évaluer toutes contaminations du laboratoire.

Réc = Récupération

(1) La récupération ou l'écart relatif (RPD) pour ce composé est en dehors des limites de contrôle, mais l'ensemble du contrôle qualité rencontre les critères d'acceptabilité pour cette analyse

Objet : **Explications de la demande d'analyses pour le projet de Agnico Eagle (Meliadine).**
Notre no de projet : #18-5528

Bonjour Argyro,

Voici la demande d'analyse concernant le dossier mentionné précédemment. Les mesures ont été effectuées du 22 au 29 septembre 2018. Les échantillons se retrouvent dans une glacière. À cela suivra plus tard les échantillons des métaux particulaires et les échantillons d'eau (# 304, 312, 320 et 328).

DEMANDE D'ANALYSES / MÉTAUX

Les fractions filtres et buse-sonde acétone vous seront envoyées un peu plus tard afin de faire l'analyse pour les métaux particulaires. Pour chacun des essais, nous voulons un résultat combiné des 2 fractions Buse-Sonde (Acétone et HNO_3) et le Filtre (donc 3 échantillons à combiner ex. éch.# 301, 302 et 303 – 309, 310 et 311 etc. Aussi, pour le Mercure d'un même essai, les fractions de $KmnO_4$ (BB56) et de HCl 8N (BB56-HCL) doivent être combinées (ex. éch.# 307 et 308). Il est important de respecter ces combinaisons exigées.

Il y a aussi les échantillons d'eau, # 304, 312, 320 et 328 qui vont arriver plus tard. L'analyse des métaux et du Hg sera également à faire.

Les métaux à analyser sont les suivants : Al, Sb, Ag, As, Ba, Be, Bi, B, Cd, Ca, Cr, Co, Cu, Sn, Fe, Li, Mg, Mn, Mo, Ni, Pb, K, Se, Na, Ti, V, Zn, Sr, Tl, Si (Silicium soluble), Hg

Il est important de ne pas jeter les échantillons et de nous les retourner après l'analyse.

Pour des renseignements supplémentaires n'hésitez pas à communiquer avec nous.

Envoyer les résultats à eric.trepanier@consul-air.com.

Salutations.

Eric Trépanier

CONSULAIR GESTION GLOBALE AIR ET ENVIRONNEMENT

F_12_V9 (2/2)

August/2018

Récupération finale du dispositif de prélèvement MÉTAUX USEPA 29

Date de récupération :	23-09-2018	Heure de récupération:	8Lxx
Pesée des barboteurs pour l'humidité:	✓	Nettoyage de l'extérieur des différentes pièces :	✓
Conditionnement des contenants de récupération :	✓		

Contenant 1 - Récupération du filtre (Séparateur principal)

Mettre le filtre dans un pétri propre et scellé (pince en polyéthylène ou teflon)	✓

Contenants 2 et 3 - Récupération de la buse et de la sonde

Items	Remarques	Brosser 100 ml Acétone	Rincer 100 ml HNO_3 0,1N	Niveau
de la buse à la partie avant du porte-filtre		✓	✓	✓

Contenant 4 - Récupération de la partie arrière du porte-filtre aux barboteurs métaux (Barb. 1-2 & 3)

Items	Remarques	Rincer 100 mL HNO_3 0.1N	Niveau	Volume (mL)
de la partie arrière du porte-filtre aux barboteurs métaux (Barb. 1-2 & 3)	BB 1234	✓	✓	334

Contenant 5 - Récupération barboteurs 4 seul

Items	Remarques	Rincer 100 ml HNO_3 0.1N	Niveau	Volume (mL)
barboteur 4	Avec 123	✓	✓	✓

Contenant 6 - Récupération barboteurs 5 et 6 ($KMnO_4$)

Items	Remarques	Rincer 100 ml $KMnO_4/H_2SO_4$	Rincer 100 ml eau	Niveau	Volume (mL)
du barboteur 5 au barboteur 6 (pot de verre ambré)		✓	✓	✓	390

Contenant 7 - Récupération barboteurs 5 et 6 ($KMnO_4$) avec HCl 8N

Items	Remarques	200 mL H_2O dans bouteille récup. Rincer 25 mL HCl 8N	Niveau	Volume (mL)
du barboteur 5 au barboteur 6		✓	✓	225

Remarques:

BB1 → HCl 180 cc

BB4 → Rincé avec BB 123 parce qu'il était vide après les tests

Blancs :

100 mL Acétone		Pour la demande d'analyse, voici les échantillons:
300 mL 0.1 N HNO_3		1a- Métaux sur contenants 1 + 2 + 3
100 mL H_2O		1b- Hg sur contenants 1 + 2 + 3
200 mL Solution H_2O_2 10% / HNO_3 5%		2a- Métaux sur contenant 4
100 mL KMnO4 4% / H2SO4 10%		2b- Hg sur contenant 4
200 mL H_2O + 25 mL HCL 8N		3a- Hg sur contenant 5
Filtre Quartz (x3)		3b- Hg sur contenant 6
		3c- Hg sur contenant 7

Appendix F-1

Toolbox presentations

Caribou Migration

- During late June to early July, herds of 1000 to 5000 Caribou cross the site for a period of 3 to 10 days.
- Environment technicians perform ground surveys 3 times per day (6:00 am, 12:00 pm, 6:00 pm) during the migration period.
- Information collected is presented on a map and a "Caribou Migration Alert" email is sent to all Meliadine Employees and Contractors.
- Alerts apply to a 5 km radius around the Project
- Alerts apply to a 100 m buffer zone along the AWAR road corridor.

When is an alert triggered?

When 50 or more Caribou are within 5km of site

What does the alert mean?

The following work must stop:

- Helicopter flights and drill operations off site*
- Surface mining/operations activities such as transportation to mining areas, hauling of material, and non-essential refueling of equipment. Non-essential light vehicle traffic will be suspended.
- Surface activities related to underground mining such as surface stockpiling of ore or waste with heavy equipment.
- Surface construction activities: outdoor construction development, earthworks, road construction, structural work, non-essential waste deposition, refueling, transportation of equipment.
- Water management activities, such as unauthorized pumping, piping installation and outdoor unapproved maintenance of water management facilities.
- Outdoor unapproved camp activities.
- Only essential light vehicle traffic (for crew changes and wildlife survey) will be authorized.
- All activities, not previously approved by the Environment Department, during a Migration Alert will require approval by the Mine Manager or acting Manager.

What activities are permitted?

Essential activities allowed:
↗ **Refueling of essential generator and power supplies;**
↗ **Operation/maintenance of water treatment systems;**
↗ **Critical inspections required in case of a malfunction;**
↗ **ERT deployment in case of a Code 1;**
↗ **Intervention in case of a reportable spill;**
↗ **Medical treatment or site evacuation of employee;**
↗ **Activity intended to prevent a health and safety or environmental risk.**

When can I resume work?

When the Environment Department notify the site by radio and email.

Please be patient during the migration period and refrain from calling the environment department for updates. During alert periods, environment staff continuously monitor the herd.

SPILL PREVENTION

What is a spill?

A spill is defined as, an accidental release of product into the environment that has the potential for adverse impacts to the receiving environment, Agnico Eagle property, or human health. This can include potential impacts to water, surface and groundwater, land, equipment, buildings, human health and the atmosphere.

Steps to follow when a spill occurs (***only if safe to do so)***

1- Stop the activity causing the spill (e.g. shut down the equipment, close the valve, etc.).
2- Contain the spill to avoid spreading the contamination (e.g. use secondary containment, build a berm or dig a trench, repair the leak, etc.)
3- Decontaminate the area (e.g. dig out the contaminated soil, pump out the contaminated liquid, etc.).
4- Segregate the material, put rags and booms in a container (quatrex or drum) and take contaminated soil to the appropriate location.
5- Complete the spill report (below), providing as much detail as possible, and send it to the environment department.

Depending on the substance and volume, the spill may need to be reported to the Government Spill Hotline within 24 hours of the incident. The *Spill Contingency Plan* outlines reportable spill volumes for specific substances. If unsure, please contact the environment department.

Spill >100 L need to be declared to Env. Dept. Immediately

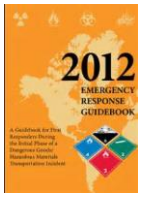
SPILL PREVENTION

How Meliadine deals with spills?

At Meliadine, all spills, regardless of size, quantity, location, or time, must be reported to the environment department, cleaned up and brought to the appropriate location.

1- Contaminated soils resulting from spills of petroleum products (motor oil, hydraulic oil, gasoline, fuel and lubricant) must be sent to the landfarm area.



2- Spills with chemical products (coolant, windshield washer, glycol, tailings, cyanide, sulfur, etc.) must be stored as Hazardous Material and shipped off site for proper disposal.

For other potentially life threatening substances & emergencies, call 3911 or radio CODE 1, CODE 1, CODE 1, or refer to the Emergency Response Plan.

AGNICO EAGLE

MONTHLY ENVIRONMENT TOPIC

SPILL PREVENTION

Preventing spills is much easier than cleaning them up. Examples of spill prevention include:

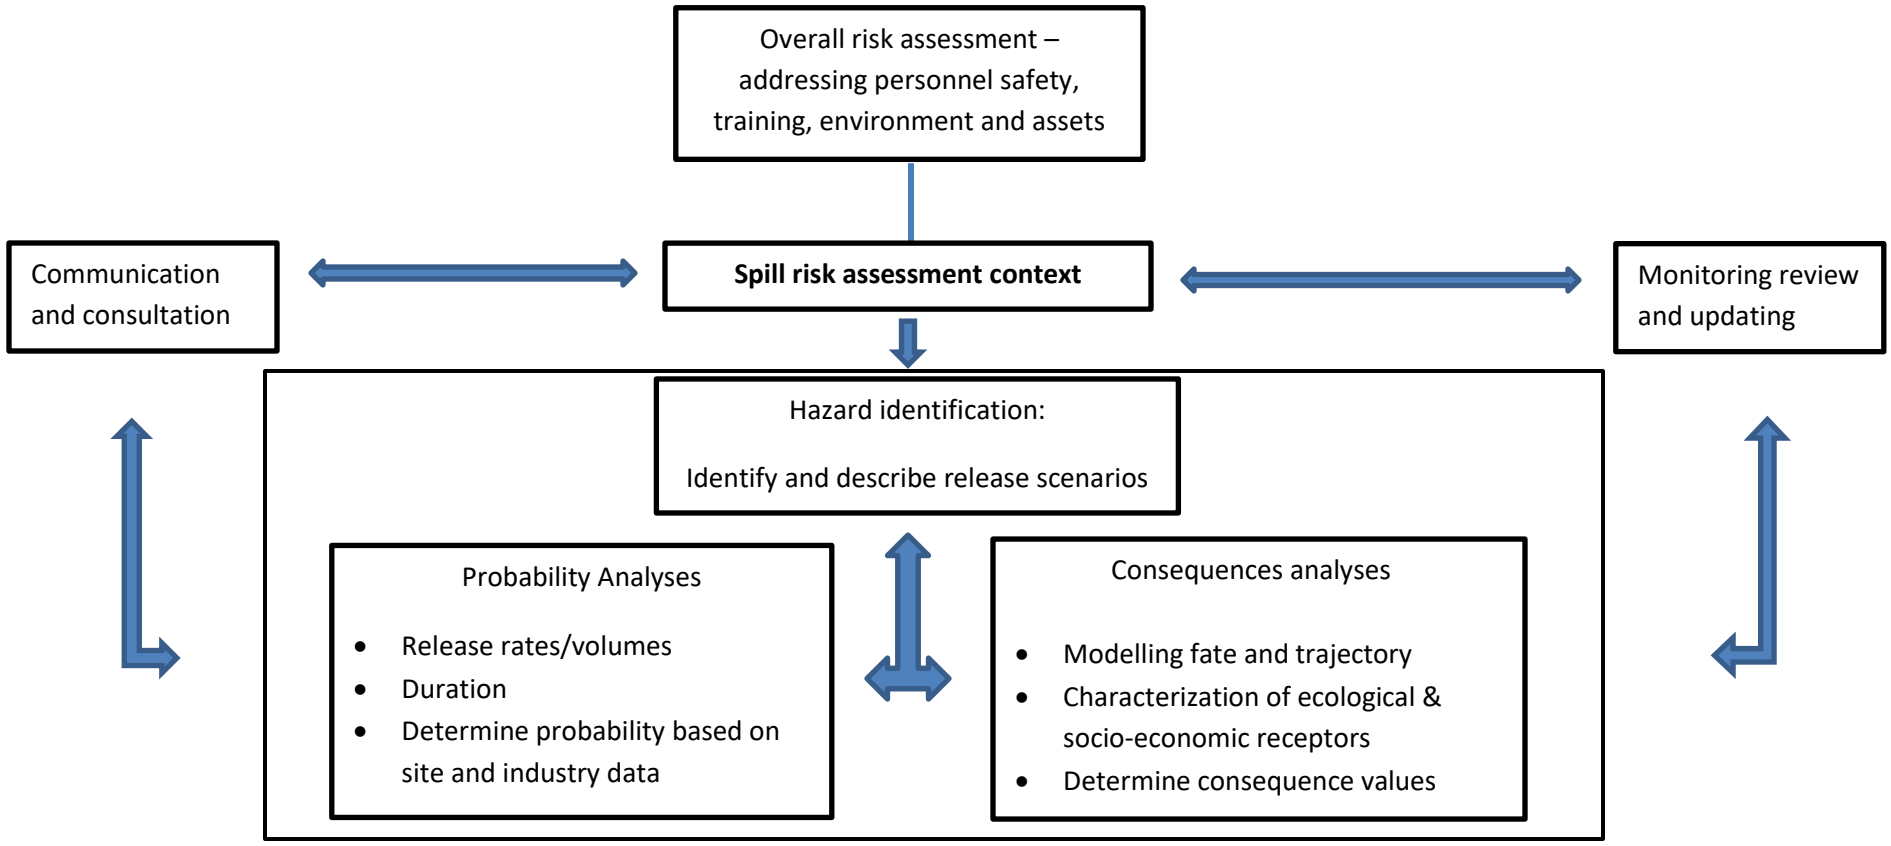
- Adhering to proper work methods and procedures

- Taking care when transferring fuel or sewage

- Maintaining equipment

- Using portable secondary containment for small containers

- Using portable secondary containment when refueling



- Installing lined secondary containment for large fuel tanks and chemical storage areas

Waste Management

WHY IS IT IMPORTANT TO BE MANAGED CORRECTLY?

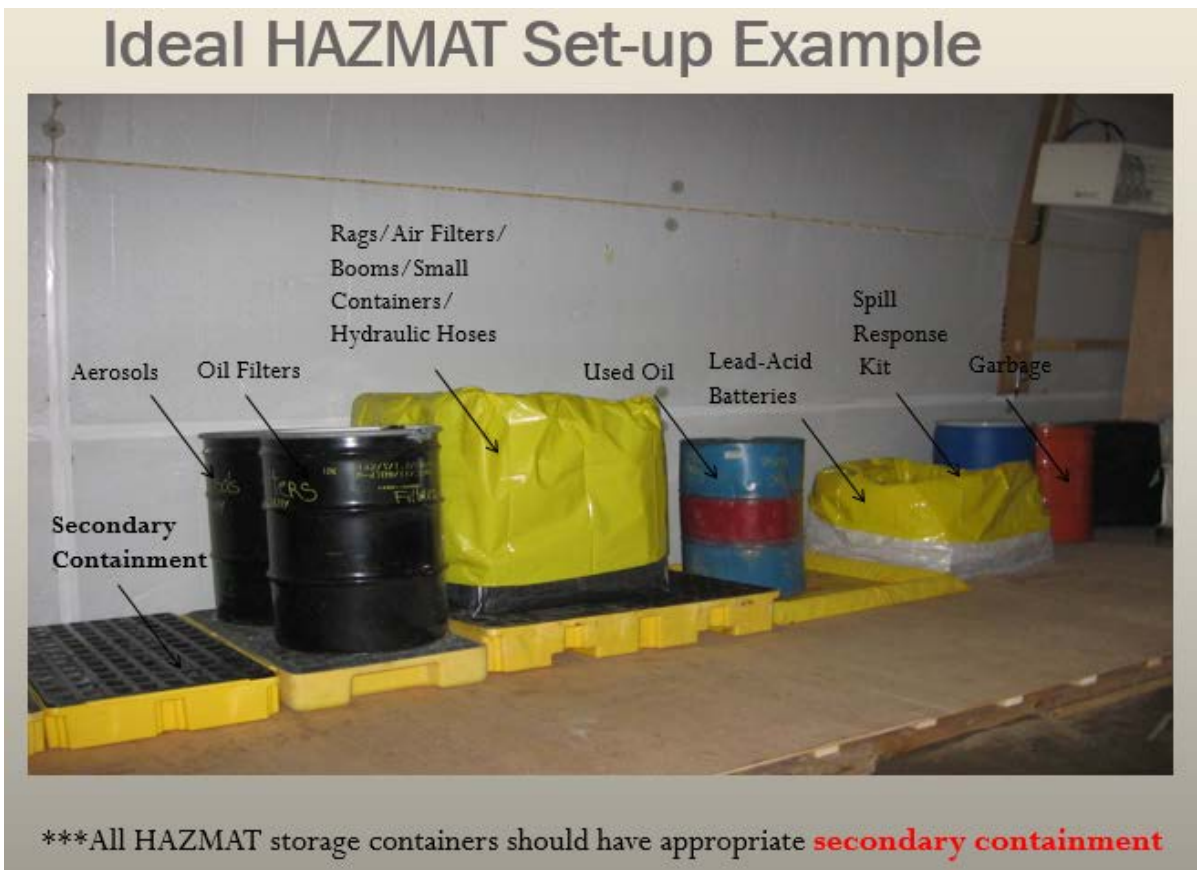
It is important to manage all waste at Site for the safety and protection of personnel, wildlife and the environment. It also saves time and improves efficiency if it is managed correctly at the source so that sorting and rework is not required.

WHO IS RESPONSIBLE FOR MANAGING WASTE?

You are all responsible! Similar to safety, all personnel at Meliadine are responsible for environment protection and this includes waste management.

HOW SHOULD IT BE MANAGED?

Segregation at the source is key to the success of any waste management program. Waste is required to be separated accordingly. This allows for increased efficiency and allows for appropriate disposal of materials.



Containment of domestic waste and hazardous waste is required. All domestic waste should be kept in a closed container with a lid to mitigate odors and access to wildlife. Secondary containment to mitigate any spills or leaking of hazardous materials is required.

Labelling all storage containers is required on Site, including seacans. →→→→→→→→→→→

Food and drinks should not be brought outside and should never be left outside.

Cigarette butts need to be disposed of inside the appropriate storage containers located at designated smoking areas and should never be disposed of on the ground, waterbodies, or on-stop of a disposal container. They need to be contained so that they will not be blown by wind where they may migrate to the ground or waterbodies nearby.

Example of Segregation, labelling and secondary containment:

WHAT IS WASTE?

Waste at the Meliadine Site includes garbage and food waste, construction materials, hazardous materials (HAZMAT) and recycling.

Examples of Waste and Segregation:

Domestic Waste, Garbage and Food Waste	Construction Waste	HAZMAT	Recycling
Paper Cardboard Food packaging Food wastes Drink boxes Food grease Coffee/coffee cups Sandwich wrappers	Air filters Cold ash Roofing materials Carpet Insulation Treated wood pallets Rubber Caulking tubes Non-contaminated: • Wood • Concrete • Metal • Plastics	Petroleum Products Waste oil Oil filters Oily solids Oil rags Paint/Paint cans Aerosol cans Batteries	Pop cans/bottles Scrap metal Electrical components Electric cable/wiring

WHAT CAN EVERYONE DO TO HELP?

In addition to segregating, labelling and keeping food and drinks inside, please ask questions. If you are unsure, ask your supervisor. If additional information is required or anything is unclear, do not hesitate to ask the Environment Department.

Take ownership and be proud to work at Meliadine. Everyone wants a clean, safe and environmentally compliant workplace to work.

Wildlife Memorandum

To all AEM employees and Contractors on the Meliadine Project and associated Facilities:

We are at time of year when our local wildlife will start being seen on a more frequent basis, such as it is every winter. Arctic Fox sightings have been on the rise over the last couple weeks.

We ask that no one tries to feed, take close-up pictures, get close to these wild creatures, or coax them to come closer. Animals that become habituated to humans generally end up being dispatched.

Arctic fox are generally timid, yet curious little animals. Naturally, these critters will not attack humans, and will be more afraid of humans than we are of them.

However, if protecting a food source, if surprised, or if cornered in a location they cannot get out of, these creatures, like any other wild animal, will defend itself. We again ask everyone on site to be sure to keep all sea cans, and doorways closed to avoid allowing access for these creatures. Please be sure to properly dispose of all food wastes in the appropriate containers to be sure there are no food attractants for these creatures.

If you are bit by an Arctic Fox, please contact the H&S Department. Offsite treatment to protect you against rabies will be required. Fox look cute and cuddly, but can carry disease and bacteria that can seriously harm humans.

When leaving a doorway and travelling outside, be sure to have a look around and proceed with caution to avoid walking up to an animal and startling it. Here are some simple rules to follow in the case of an encounter:

- Respect them – they are wild
- Be alert at all times
- If you encounter one, back away slowly
- Make noise – don't surprise animals
- Close Sea can doors
- Be cautious in noisy areas
- Do not approach them
- ABOVE ALL; NEVER FEED THEM!!!

IMPORTANT: Any person caught feeding or coaxing animals or disposing of food related waste in an improper manner, including not disposing of food waste in the proper containers or disposing at the landfill, will be met with disciplinary measures.

Please find the Meliadine Wildlife Pamphlet below as well.

If wildlife is seen, please call the Environment Department on camp channel or at extension 3903 or 3925.

Supervisors, please review with you crews.

Thank you for your cooperation,

Meliadine Environment Department

Mock scenario report

AGNICO EAGLE

On August 4, 2018 the AEM Environment Department conducted a mock spill event at the Itivia refueling station/tank farm with AEM emergency response (ERT) members, Orbit Garant Environmental/health and safety AEM warehouse staff, AEM Site Service/HTO vice president and AEM community relations personnel., Spill Training contractor, Nunatta Environmental was on site to assist and provide advice/training, The Rankin Inlet Fire Chief also attended the event as an observer.

An AEM ENV Tech documented the spill response actions and acted as the "Control Room" responder, Rankin Inlet dispatch and the ENV Tech/ENV Coordinator on site.

The mock scenario involved a broken fuel line fitting at the onshore receiving manifold during refueling (from offshore ship) of the fuel storage tanks at Itivia.

14:12 – Spill occurs (4000 L of leaking fuel towards the shoreline) Dave Loder spotted fuel leaking from the broken fitting/line

14:13 – ERT responder calls the vessel to stop transfer of fuel ASAP and relays the message of a leaking fitting to the Captain.

14:18 - Confirmation from the Captain that the transfer has stopped. During that time, AEM Site Service blocked the access to the area and called "CODE 1" to Rankin Inlet dispatch and requested to have environmental personnel contact ERT responder on the radio.

14:19- ERT responder asks ENV Coordinator to contact the coast guard
14:20 – ERT responder requested heavy equipment from construction/site services to dig a trench (no operators in area)

14:25 – Fire Marshall from Rankin Inlet arrived (did not participate but was ready with staff if assistance needed assistance)

14:25- AEM Warehouse staff from Itivia and started deploying booms along coast from emergency sea-can/ ERT responder supported.

14:38- Additional AEM Environment Dep't staff were travelling on the road to Meliadine site when the "CODE 1" was called (came to Itivia to provide support) and helped deploy absorbent booms and rags as ERT responder instructed.

15:50 – full ERT team arrived for assistance- First ERT responder (Commander) instructed immediate deployment of marine curtain (water was too rough 80 km/hr winds- did not want to put anyone's safety at risk; deployed on shore)

16:00 – More absorbent booms are placed in front of the marine barrier to collect spill and prevent it from going under marine barrier- no operators present for heavy equipment; ERT and environment staff attempted to make a trench – did not succeed due to bed rock

16:04 – Absorbent padding was placed on top of spill where visible product was observed behind marine barrier (wind blowing toward shore)

17:25 – ERT, ENV and Agnico staff declare the spill has been contained and absorbed; called off the ”CODE 1” and spill report prepared with follow up investigation of event.

Summary:

Nunatta - guided and assisted AEM staff (total 14 on site) to implement the correct procedures and equipment handling to successfully participate in the mock spill training event (fuel leak/water); the ERT commander did a great job of delegating responsibilities with everyone; all communication was satisfactory during the event. Heavy equipment (excavator) would be required as the area is underlain be bedrock – shovels and picks were not effective to dig a collection trench. It took 23 minutes for the spill to go from the pipe connection to the marine barrier- it would in a realistic scenario take ERT a minimum of 1 hour (It took 1.5hr) to get from Meliadine to Rankin Inlet (includes time to prepare) and Environment Dep’t staff members could mobilize within 50 minutes. In order to provide additional line of defense to capture fugitive oil/fuel spills the overburden on the inter-tidal zone should be removed so that loose absorbent can be spread. Nunatta advised that we contact Department of Fisheries and Oceans and ask if we can remove some rock along the beach in case of an emergency (this is fish habitat). A collection trench or sump would reduce the speed of any spill.

AEM and Nunatta Comments/Recommendations

- Buoys that can be attached to the maritime barrier or the fuel line were not blown up- these should be blown up prior to refueling season
- Sea-cans that contain Emergency environmental spill response should be placed together (one is placed on top of hill- these sea-cans should be placed as close to the shore manifold as possible)
- Shore line where fuel line connects should be cleaned of all obstructions to prevent injury to staff and damaging the containment booms
- Life jackets or mustang suits must be worn while working near the water and/or on boats
- It’s required that AEM warehouse staff working at Itivia area review the OPEP and Emergency Response Plan with ENV Tech prior to barge/fuel transfer season (both rotations)
- AEM observed that the OPEP and Spill Contingency plan was located in the Itivia warehouse office
- Follow up with DFO; if strip of overburden can be removed from inter-tidal zone to facilitate spill response and pro spill prevention measures
- Order more shackles
- OPEP should include the local municipality emergency numbers (I included this document in the PDF)
- AEM and ERT members will conduct annual training with Environment Dep’t staff.
- Lighter anchors (20 pound range) for the boat (ordered); currently have 60 pound anchors

On January 31st, a sewage spill occurred at a lift station by the Meliadine main camp STP. At approximately 15:00, a leak from the discharge pipe of a lift station was noticed by personnel and was immediately reported to the Site Services and Environment departments. It was determined that a leak from a rubber joint was the source of the spill. The lift station was shutdown and the joint is being replaced with a mechanical joint. Due to the extreme cold weather, the sewage froze immediately around the lift station. The impacted area is minimal and did not reach any water bodies.

A follow-up report will be submitted within 30 days.

Follow Up Report – January 31st 2018 Sewage Spill #18-027

Description of Spill:

On January 31st, a sewage spill occurred at a lift station by the Meliadine main camp STP. At approximately 15:00, a leak from the discharge pipe of a lift station was noticed by personnel and was immediately reported to the Site Services and Environment departments. It was determined that a leak from a rubber joint was the source of the spill. The lift station was shut down and the joint replaced with a mechanical joint. Due to the extreme cold weather, the sewage froze immediately around the lift station. Approximately 500L of sewage was spilt. The impacted area is minimal and did not reach any water bodies.

Spill Location:

The spill occurred at the Meliadine main camp sewage treatment plant. The fluid flowed from the lift station, pasted the sewage treatment plant, and ceased flowing approximately 20m from the source. The spill covered an area of approximately $10m^2$.

Figure 1: View from above – Main Camp: Location of lift station piping (source of leak) and spill area.

Spill cause:

A rubber joint on the sewage treatment plant piping failed. The equipment failure was likely due to the material fatiguing in frigid temperatures.

Spill response:

The spill froze to the immediate area and was excavated and disposed of appropriately. The joint has been replaced with a mechanical joint made of more suitable material. A third party review of the system was completed and recommendations have been provided to Agnico Eagle for implementation in order to improve the performance of the STP.

On February 2nd, during an inspection of the exploration camp retention tanks it was noticed by a member of the Site Services team that water was flowing on to Meliadine Lake near the discharge area of the sewage treatment plant. The environment department and site services supervisor were notified immediately and an inspection was conducted to determine the source of the water. it was discovered that a valve at the base of one of the retention tanks had been left open, resulting in the draining of the contents of all 4 tanks (connected in series). Discharge from the sewage treatment plant had been suspended since November 2017 due to exceedances. The quality of the substance is to be verified and is likely not deleterious.

Follow Up Report – February 2nd 2018 MEL-07 Treated Water Discharge

Description of Exceedance:

On February 2nd, during an inspection of the exploration camp retention tanks it was noticed by a member of the Site Services team that water was flowing on to Meliadine Lake near the discharge area of the sewage treatment plant. The environment department and site services supervisor were notified immediately and an inspection was conducted to determine the source of the water. It was discovered that a valve at the base of one of the retention tanks had been left open, resulting in the draining of the contents of all four tanks, which are connected in series. Discharge from the sewage treatment plant had been suspended since November 2017 due to exceedances.

Samples were collected from a melt channel in the ice, and sent for laboratory analysis. A spill report was issued on February 2nd 2018 through the NT-NU Spill Report. As a response to the spill report issued, Christine Wilson (INAC) visited the Meliadine Exploration Camp on February 2nd 2018, and was unable to collect a representative sample, as there was no pooling on the surface of the ice.

Jeff Tulugak (KIA) also inspected the spill area on February 2nd, 2018. A telephone inquiry was received by Craig Broom (Environment Canada) and Dan Gorton provided an account of the spill information available to date on February 5th, 2018.

Picture 1: Channel formed by release water flowing through ice into Meliadine Lake.

Picture 2: Release valve left open causing the spill.

Picture 3: Discharge hose connected to retention tank release valve.

Samples were collected from the STP release valve on February 2nd, shortly after the release occurred. The samples did not arrive at the laboratory within the recommended 24 hours timeframe for fecal coliform analysis. The delay was due to the delivery not being picked up at the airport by the receiving party. Total coliforms were expressed in MPN as opposed to CFU, which are the recommended units in the water license. Although these are not the preferred units, they can be converted.

Table 1: Laboratory analysis of retention tank treated water samples collected at spill site.

The sample collected from the retention tank discharge had **214 MPN/100mL fecals** and **285 MPN/100mL E.coli.**

Spill Discharge Location:

The MEL-07 effluent discharges to land at a location situated approximately 65 m from the ordinary high water mark of Meliadine Lake (see Figure 1). Once the effluent reaches the end of the pipe, it travels along a rock channel intended to reduce the flow and prevent erosion. The effluent will then follow the rock channel to Meliadine Lake. It is expected that with the extreme cold temperatures on February 2nd, and the fact that the effluent discharges to land first, the bacteria would likely not have survived.

Figure 1: View from above - MEL-07 discharge configuration with rock channel and flow path to Meliadine Lake

Spill cause:

Investigation into the release was inconclusive. However, it is believed that a water truck operator failed to close the release valve after transferring water to a truck.

Spill response:

The release was deemed to be caused by human error. The release valve is now fitted with a locking mechanism. A supervisor now keeps a register to record which operator is in possession of the key.

Dan Gorton, Environmental Coordinator, AEM

At around 16:45 pm on February 18th Richard Montreuil was passing by the fuel tank farm and notice that a flexible hose was spreading fuel on the ground. He inform Francis Lecours which stop immediately the fuel transfer to the raise ventilation tank (linked to the same pipe line). Richard called Environment on the radio to have support for the spill remediation.

Actions Taken: Stopped fuel transfer, called Environment Department, contained the fuel spill with spill kit available in the spill trailer, proceeded with pumping and collecting spilled fuel and absorbent materials

Actions to be Taken: As the cause of the spill is an human error by not respecting all steps included in a JHA, we did create a procedural check list to ensure that all steps are done and executed correct

Follow Up Report:
February 18, 2018 Fuel Tank Farm Spill

Description of Exceedance:

On February 18, 2018 a fuel spill was reported at the fuel tank farm. The spill occurred after the commissioning of the system, while transferring fuel to the Portal 1 fuel storage tank. A valve was left opened and not locked out at a connection that transferred fuel to the gas boy. Visual observations during the fuel transfer to the Portal 1 fuel storage tank showed that fuel was spilling out of the gas boy fuel line. Upon immediate observation of the spill, the system was shut down and no additional spill volumes occurred. During the fuel transfer, 1,022 liters of fuel were transferred to the Portal 1 fuel storage tank and approximately 6,500 liters were released to the environment in the area around the gas boy. This volume was calculated from instrumentation readings. No contaminants reached any water body.

Spill response:

E&I personnel were at the spill location during the occurrence. The Environment department was contacted immediately and straw logs and spill absorbent pads were mobilized to contain the fuel spill and to prevent the transport of contaminant away from the spill area. Due to the position of the fuel tanks located within the spill area near the gas boy, fuel spilled under the tanks was not easily accessed to be absorbed and disposed of as hazmat. There was extremely cold temperatures at this time (approximately -70 ^{o}C) and the ground where the spill occurred was frozen and the fuel also froze.

Spill Cleanup:

Once control of the spill site was obtained, spill cleanup activities were initiated. Approximately 4,500 l of free product was collected by pump to storage drums and totes. The collected free product is planned to be recycled as fuel for operating the incinerator at Site. Approximately 140 m^3 of snow and frozen fuel was removed and placed in the License A Landfarm. Since the area under the fuel tanks was not easily accessed for excavation, the tanks are currently being emptied so that they can be disconnected and removed so that equipment can access the area to complete the spill clean-up by excavating the area to remove any remaining fuel from the spill.

Spill Cause and Corrective Measures

The operator failed to close and lock-out a valve prior to initiating the fuel transfer. The spill was caused by human error, by not respecting all steps included in a JHA. A procedural check list was drafted to ensure that all steps are completed and executed correctly during future fuel transfers.

While conducting a routine inspection of the Itivia construction site on May 27th, turbid surface run-off water was observed crossing over a roadway and through a culvert into Melvin Bay. As per the obligations under the Nunavut Water Board License 2AM-MEL1631, Part D, item 18 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act., samples were collected for laboratory analysis to assess the TSS concentration and other water quality parameters. The laboratory results were received on June 15th and showed that TSS concentrations exceeded those outlined in the Type A water license for discharge/release into a water body.

License Limit = 100 mg/L (maximum concentration of any grab sample)
Analysis results = 500 and 1200 mg/L

Follow Up Report: #18-231
May 27, 2018 Itivia Surface Water Run-off

Description of Exceedance:

While conducting a routine inspection of the Itivia construction site on May 27th, turbid surface water run-off was observed crossing over a roadway and through a culvert into Melvin Bay.

Spill response:

As per the obligations under the Nunavut Water Board License 2AM-MEL1631, Part D, item 18 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act., samples were collected for laboratory analysis to assess the TSS concentration and other water quality parameters. The laboratory results were received on June 15th and showed that TSS concentrations exceeded those outlined in the Type A water license for discharge/release into a water body.

Spill Cleanup:

Clean up was not applicable as surface water run-off diluted into seawater.

Spill Cause and Corrective Measures

Run-off was caused by snow melting inside and outside the site disturbance area. A sediment trap was created using gravel and straw logs prior to the run-off event being sampled. The sediment traps were not effective enough to reduce TSS below acceptable levels. Improving the snow management plan and following the procedure will help reduce run-off volumes in the future.

Picture 1: Sampling location between access road and Melvin Bay.

Picture 2: Sample location immediately after sediment controls at culvert.

While conducting a routine inspection of the Itivia construction site on June 3rd, turbid surface run-off water was observed flowing into Melvin Bay from the eastern entrance to the bypass road. As per the obligations under the Nunavut Water Board License 2AM-MEL1631, Part D, item 18 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act., samples were collected for laboratory analysis to assess the TSS concentration and other water quality parameters. The laboratory results were received on June 21st and showed that TSS concentrations exceeded those outlined in the Type A water license for discharge/release into a water body.

License Limit = 100 mg/L (maximum concentration of any grab sample)
Analysis results = 420 mg/L

Follow Up Report: #18-247
June 3rd, 2018 Itivia Surface Water Run-off

Description of Exceedance:

While conducting a routine inspection of the Itivia construction site on June 3rd, turbid surface run-off water was observed flowing into Melvin Bay from the eastern entrance to the bypass road. This is an area of foreshore with a gentle gradient. The sampling location is referred to as SR11.

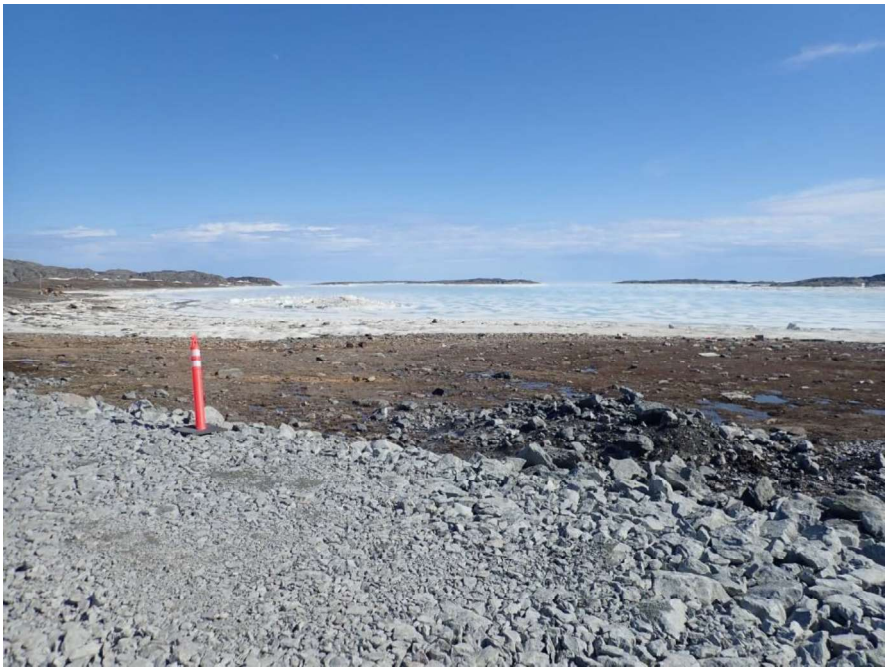
Figure 1: Sample location at Melvin Bay foreshore

Spill response:

As per the obligations under the Nunavut Water Board License 2AM-MEL1631, Part D, item 18 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act., samples were collected for laboratory analysis to assess the TSS concentration and other water quality parameters. The laboratory results were received on June 21st and showed that TSS concentrations exceeded those outlined in the Type A water license for discharge/release into a water body. The license limit for any grab sample is 100mg/L while the sample analysis reading was 420mg/L.

Spill Cleanup:

Clean up was not appropriate as surface water run-off diluted into seawater.



Spill Cause and Corrective Measures

Run-off was caused by snow melting inside and outside the site disturbance area. A sediment trap was created using straw logs prior to the run-off event being sampled. The sediment traps were not effective enough to reduce TSS below acceptable levels. Improving the snow management plan and following the procedure will help reduce run-off volumes in the future.

*Add a map showing the area and where SR-11 was taken. I think Justin has already produced this map.

Picture 1: Straw log sediment trap between Bypass Road entrance at Itivia and Melvin Bay.

Picture 2: Run-off area from Bypass Road entrance at Itivia to Melvin Bay.

Picture 3: Run-off area from Bypass Road entrance at Itivia to Melvin Bay.

Drilling activities have been underway near Lake B8 and a small drip from a hydraulic hose in the drilling shack was observed when the drill was being demobilized from the location. The hose was dripping for an unknown duration, however, maintenance and a hose change was conducted approximately 3-weeks prior to the spill report. Lake B8 is a non-fish bearing lake. Despite B8 being non-fish bearing lake, it remains a non-contact water body as part of Meliadine's Water Management Plan until the dike D-CP4 is constructed and B8 becomes containment pond CP4. At present moment, the impact to B8 is expected to be minimal; however, ongoing spill clean up and observations are planned as snow and ice thaws at this location (GPS UTM 83 Z015: 539096.07, 6988864.61, 1006.40). The drill will be inspected and repaired prior to starting at the next location and better secondary containment to be sought to reduce risks from hose drips. Spill report by Jennifer Brown 819-759-3555 ext. 3996

Follow Up Report – #18-213
June 8th 2018 Drill 3 Hydraulic Oil Spill at B8

Description of Exceedance:

Drilling activities have been underway near Lake B8 and a small drip from a hydraulic hose in the drilling shack was observed when the drill was being demobilized from the location. The hose was dripping for an unknown duration, however, maintenance and a hose change was conducted approximately 3-weeks prior to the spill report. Lake B8 is a non-fish bearing lake. Despite B8 being non-fish bearing lake, it remains a non-contact water body as part of Meliadine's Water Management Plan until the dike D-CP4 is constructed and B8 becomes containment pond CP4. At present moment, the impact to B8 is expected to be minimal; however, ongoing spill clean-up and observations are planned as snow and ice thaws at this location (GPS UTM 83 Z015: 539096.07, 6988864.61, 1006.40).

Spill response:

Booms were placed around the spill area to prevent hydrocarbon flow to B8. Some contaminated soil was removed and placed in the landfarm.

Figure 1: Booms placed downstream of spill location.

Spill Cleanup:

A shop-vac was used to remove hydraulic oil observed on surface and peat moss was placed to help remediate the area. The area was inspected on 22nd June, 2018. No flowing water was observed. Booms were removed and disposed of appropriately as Hazmat.

Spill Cause and Corrective Measures

The drill will be inspected and repaired prior to starting at the next location and better secondary containment to be sought to reduce risks from hose drips.

While conducting a routine inspection of the Itivia construction site on June 10th 2018, surface run-off water was observed flowing through a culvert into Melvin Bay. Samples were collected for laboratory analysis to assess the TSS concentration and other water quality parameters. The laboratory results were received on June 25th and 160 mg/L TSS was measured. This exceeds the license limit of 100 mg/L TSS as outlined in the Type A water license for discharge/release into a water body. Discharge and flow rate were minimal, and caused by light rain and snow melt.
A follow-up report with additional details will be provided.

The exceedance is being reported under the Nunavut Water Board License 2AM-MEL1631, Part D, item 18 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act
License Limit = 100 mg/L (maximum concentration of any grab sample)

Follow Up Report: #18-251
June 10, 2018 Itivia Surface Water Run-off

Description of Exceedance:

While conducting a routine inspection of the Itivia construction site on June 10, 2018, surface run-off water was observed flowing through a culvert into Melvin Bay. Samples were collected for laboratory analysis to assess the TSS concentration and other water quality parameters. The laboratory results were received on June 25, 2018 and a concentration of 160 mg/L TSS was measured. This exceeded the water quality criteria of 100 mg/L TSS, as outlined in part D, item 18 of the NWB Water Licence 2AM-MEL1631 for TSS discharge/release into a water body. Discharge and flow rate were minimal, and caused by light rain and snow melt.

The sampling location is referred to as SR1 and is shown in Figure 1.

Figure 1: Sample location SR-1 shown at Itivia Laydown

Spill Cleanup:

Straw logs were placed downstream of the culvert to reduce TSS.

Spill Cause and Corrective Measures

Run-off was caused by snow melting inside and outside the site disturbance area. Due to changes in the topography of the quarry, surface water is directed back towards the approved disturbance area, away from the quarry boundary. The decantation sump down-stream of the culvert had been repaired to minimize additional TSS flow during possible future rain periods. Silt fences and straw logs have been installed upstream of the site and are inspected weekly. A third party consultant has inspected the area to recommend improvements to mitigate and reduce erosion and sediment control. A final report on the consultant findings will be issued on August 24th.

As the ground started to thaw, the building sank into the ground which induced strain on the connection for the discharge line. This resulted in the line disconnecting and when the lift station level reached its preset level started the pumps and the effluent discharged inside the building and eventually leaked onto the ground. Sewage was removed with a hydro suction truck and stored for sewage treatment discharge.

Follow Up Report –
June 12th 2018 Sewage Spill #18-223

Description of Spill:

As the ground started to thaw, the building sank into the ground which induced strain on the connection for the discharge line. This resulted in the line disconnecting and when the lift station level reached its preset level the pumps started and the effluent discharged inside the building and eventually leaked onto the ground. The impacted area is minimal and did not reach any water bodies.

Spill Location:

The spill occurred at the Meliadine main camp sewage treatment plant. The fluid flowed from the lift station, pasted the sewage treatment plant, and ceased flowing approximately 20m from the source. The spill covered an area of approximately $10m^2$.

Figure 1: View from above – Main Camp: Location of lift station piping (source of leak) and spill area.

Spill cause:

The building housing the STP sunk into the ground due to thawing ground conditions causing the discharge line to disconnect from the lift station.

Spill response:

Sewage was removed with a hydro suction truck and stored for sewage treatment discharge.

On July 8, 2018, a sewage sludge spill occurred at the Main-STP at the Meliadine Site. During the night a pump failed on the membrane train #2. Approximately 200 L outside the STP onto the ground. The membrane #1 continue running normally, but the recirculating sludge was backfilling the membrane #2 tank as there is no check valve on the three way junction for the activated sludge recirculating pipe. This action overfilled the tank and caused overflow. A check valve will be installed. The impacted area is with the footprint of the mine and did not reach any water bodies.

A follow-up report will be provided.

Follow Up Report – 18-287
July 8th 2018 Sewage Spill

Description of Spill:

On July 8, 2018, a sewage sludge spill occurred at the Main-STP at the Meliadine Site. During the night a pump failed on the membrane train #2. Approximately 200 L overflowed outside the STP onto the ground.

Spill Location:

The spill occurred at the Meliadine main camp sewage treatment plant. The sewage flowed from the sewage treatment plant to the ground. The impacted area is within the footprint of the mine and did not reach any water bodies.

Figure 1: View from above – Main Camp: Location of Sewage Treatment Plant.

Spill cause:

The membrane #1 continue running normally, but the recirculating sludge was backfilling the membrane #2 tank as there was no check valve on the three way junction for the activated sludge recirculating pipe. This action overfilled the tank and caused overflow.

Spill response:

Sewage was removed with a hydro suction truck and stored for sewage treatment discharge.

Spill Mitigation:

A check valve was installed.

While conducting an inspection of the Itivia construction site on July 11th, it was noted that hydraulic oil from equipment spilled to road base material on the bypass road. The spill was cleaned up and reported internally as it was outside the 31m high water mark. After discussion with INAC it was explained that the spill should be reported as it was within 31m of a fish bearing waterway, which feeds into the bay. The volume was estimated at 5L. The spill was cleaned up before it had time to disperse into the road base.
This spill is being reported as per part H, item 9 of the 2AM-MEL1631 Water License.
A follow-up report will be issued.

Follow Up Report: #18-279
July 11, 2018 Itivia Hydraulic Hose Failure

Description of Incident:

While conducting an inspection of the Itivia construction site on July 11th, it was noted that hydraulic oil from equipment spilled to the road base material on the bypass road. The spill was cleaned up and reported internally as it was observed as outside the 31 m high water mark. After discussion with INAC it was explained that the spill should be reported as it was within 31 m of a fish bearing waterway, which feeds into Melvin Bay. The volume was estimated at 5 L.

Spill Cleanup:

The spill was cleaned up with absorbent pads before it had time to disperse into the road base.

Spill Cause and Corrective Measures

The spill was caused by equipment failure. Maintenance is scheduled regularly for all equipment at Site and spill kits are required to be stored inside all vehicles. The Environment Department conducts quarterly vehicle spill kit inventory audits to ensure availability and quick response to a timely and efficient cleanup to mitigate spill migration.

On July 20th, after loading a water truck with treated water from the retention tank at exploration camp's Sewage Treatment Plant, the operator proceeded to drive towards the discharge location at CP1. On his way a colleague contacted him informing that the truck was leaking water.
The truck driver stopped and found that the valve rear was opened, proceeded to closing the valve. Approximately 3000 L of treated effluent was spilled on the road between the exploration camp and CP1 for an estimated distance of 500m. The treated effluent did not extend beyond the road surface and had evaporated or seeped into the road making it difficult to clean it up. The treated effluent did not flow outside of the site's managed water area or into any waterbody. A follow up report with further details will be provided

Follow Up Report: #18-289
July 20, 2018 Treated Sewage Effluent

Description of Incident:

On July 20th, after loading a water truck with treated water from the treated retention tank at the Exploration camp's Sewage Treatment Plant, the operator proceeded to drive towards the discharge location at CP1. During transport, the operator was advised by an observer that the truck was leaking water.

Spill Response & Cleanup:

The truck driver stopped and found that the valve rear was opened and closed the valve.

Approximately 3000 L of treated effluent had drained from the water truck to the road, between the exploration camp and CP1, an estimated distance of 500 m. The treated effluent did not extend beyond the road surface and had evaporated or seeped into the road making it difficult to clean it up. The effluent was treated and did not flow outside the Site's managed water area or into any water body.

Spill Cause and Corrective Measures

The spill was caused by human error with the training and procedure not followed. The employee has been suspended from operating mobile equipment and is required to successfully complete additional equipment training prior to being assigned equipment operating tasks.

A sample of treated water from Mel-14 (final discharge point to Meliadine Lake) was collected on July 23, 2018. Upon receiving the sampling results, the total aluminum concentration was found to be 4.39 mg/L which exceeded the permitted discharge limit of 2 mg/L. When the exceedance was observed, the lab was requested to re-analyze the sample to determine if the result was an outlier; however, the sample had been disposed of and re-analysis was not possible at the date of the request.

This spill is being reported as per the 2AM-MEL1631 Nunavut Water Board License, part F item 3.

A follow up report will be issued.

AGNICO EAGLE
MELIADINE

Follow Up Report: #18-409
July 23, 2018 MEL-14 Aluminum Concentration Criteria Exceeded

Description of Incident:

A sample of treated water from MEL-14 (final effluent sampling port prior to discharge to Meliadine Lake) was collected on July 23, 2018. Upon review of the laboratory analysis results, the total aluminum concentration was found to be 4.39 mg/L which exceeded the permitted discharge limit of 2 mg/L.
As per the obligations under the Nunavut Water Board License 2AM-MEL1631, Part F, item 3 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act., samples were collected for laboratory analysis to assess the total metal concentrations and other water quality parameters during final effluent discharge at MEL-14. The laboratory results were received on August 8, 2018, however, the exceeded criteria for the total aluminum concentration was not observed at the initial time of the data review and data input. During the quarterly reporting for MDMER-EEM (RIIS) on October 1, 2018, the exceeded concentration was observed and reported immediately.

Exceedance Cause and Corrective Measures

The exceeded criteria for final effluent discharge criteria for total aluminum concentrations is assumed to be a laboratory error. When the exceeded criteria was observed, the lab was requested to re-analyze the sample to determine if the reported concentration was a result of laboratory error; however, the sample had been disposed of and re-analysis was not possible at the date of the request.

When comparing the total aluminum concentrations from a sample collected and analyzed on the same day from MEL-13 (the discharge location at Meliadine Lake), total aluminum concentrations were also elevated (6.64 mg/L). Results for total aluminum concentration were then compared to results from 2018 sampling events. The results from July 23, 2018 had the maximum concentrations for both MEL-13 and MEL-14. Table 1 presents a summary of laboratory analysis for MEL-13 and MEL-14 in 2018 and includes the minimum, maximum and average total aluminum concentrations for samples collected in 2018. Figure 1 shows the aluminum concentrations for MEL-13 and MEL-14 in 2018. No other samples collected and analyzed in 2018 have exceeded criteria concentrations for total aluminum at MEL-14.

The Environment Department at Meliadine is currently implementing a data management system for laboratory results. Once it has been fully commissioned, it should mitigate delays with reporting criteria exceedances and improve the timing for requests that may be made if re-analysis is required at the laboratory.

Table 1 Summary of MEL-13 and MEL-14 Total Aluminum Analysis:

MEL 13

On August 2, 2018, the water truck operator was collecting the treated STP effluent from the retention tanks at MEL-07 and the truck was overfilled and spilled out onto the road under the water truck. Some water spilled down the bank to the spillway that was previously used for the MEL-07 discharge. No water migration to Meliadine Lake was observed. An investigation is underway to determine the cause of the incident. Upon completion, a follow up report will be issued.

This spill is being reported as per part H, item 4 of the 2BB-MEL1424 Water Licence.

Follow Up Report: #18-308
August 2, 2018 Treated Sewage Effluent

Description of Incident:

On August 2, 2018, the water truck operator was collecting the treated STP effluent from the retention tanks at MEL-07. The truck was overfilled and spilled out onto the road under the water truck. Some water spilled down the bank to the spillway that was previously used for the MEL-07 discharge.

Spill Response & Cleanup:

When the truck operated observed that the treated effluent was overflowing, pumping was halted.

Approximately 1,600 liters of treated effluent water spilled to the access road behind wing “P” at the Exploration Camp and some observed spill towards the rock bed channel. No water migration to Meliadine Lake was observed and the treated water was quickly absorbed into the road or evaporated.

Spill Cause and Corrective Measures

The spill was caused by human error with the training and procedure not followed. The supervisor of the employee has discussed corrective measure with the operator.

Follow Up Report: #18-378
August 19, 2018 MEL-14 TDS Concentration Criteria Exceeded

Description of Incident:

A sample of treated water from MEL-14 (final effluent sampling port prior to discharge to Meliadine Lake) was collected on August 19, 2018. Upon review of the laboratory analysis results, the total dissolved solids (TDS) concentration was found to be 1,430 mg/L which exceeded the permitted discharge limit of 1,400 mg/L.

As per the obligations under the Nunavut Water Board License 2AM-MEL1631, Part F, item 3 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act., samples were collected for laboratory analysis to assess TDS concentrations and other water quality parameters during final effluent discharge at MEL-14. The laboratory results were received on September 13, 2018 and reviewed and reported on September 15, 2018. With regards to your question on reporting delay, due to the remote location and the extensive list of parameters that we sample for the Mel-14 sample, the delay in receiving results from the lab is generally 3-4 weeks. This is because the lab sub-contracts part of the analysis to their sister lab in Burnaby BC, so it can take a while for the sample to be received and processed.

Cause and Corrective Measures

The sample was collected at 10:30 am on August 19, 2018. During this time, there was an unscheduled power outage and effluent release had stopped at the effluent water treatment plant (EWTP). Water was not pumped through the sampling port located at MEL-14 during this time. The person that conducted the sampling was a summer intern student who has returned to school and the sampling conditions and confirmation of the location that the sample was collected has not been verified. Based on the field parameter monitoring, the power outage, review of laboratory results from previous and post sampling events, the TDS concentrations reported from the laboratory analysis for MEL-14 on August 19, 2019 are assumed to be not representative for the final effluent discharged the sampling port for MEL-14 to Meliadine Lake. It is possible that it was sampled from a port that was not treated and not discharging to Meliadine Lake.

Table 1 presents the operational report, which summarizes the monitoring results at the EWTP on August 19, 2018. Table 2 presents the daily volume effluents discharged at MEL-14 to Meliadine Lake in August 2018.

Training for all personnel responsible has been conducted to ensure that future MEL-14 sampling is always collected from the same location, after treatment when the power and pumps are working. In addition,

the Environment Department at Meliadine is currently implementing a data management system for laboratory results. Once it has been fully commissioned, it should mitigate delays with reporting criteria exceedances and improve the timing for requests that may be made if re-analysis is required at the laboratory.

Agnico eagle understands the importance to meet water quality discharge criteria without exceedances. All departments involved discussed the EWTP changes or updates daily in a morning water management meeting and the monitoring and comparisons of data was an important part of a decision-making process.

As sewage enters the lift station, pressure is applied on the fixed piping. The pressure caused the fixed piping to come uncoupled. This resulted in a spill of approximately 400 L at the lift station on the ground. The lift station was shut down and repaired. New flexible piping is being ordered for this application to prevent re-occurrence. Spilled sewage was cleaned up. No contaminants reached any water body. This spill is being reported as per the 2AM-MEL1631 Nunavut Water Board License, part H item 8.

A follow up report will be issued.

Follow Up Report: #18-344
August 25, 2018 Sewage Spill

Description of Incident:

On August 25, 2018 at approximately 10:00, a sewage spill was observed and reported at the MSB sewage lift station. As sewage entered the lift station, pressure was applied on the fixed piping. The pressure caused the fixed piping to come uncoupled. This resulted in a spill of approximately 200 L at the lift station and onto the ground. No contaminants reached any water body.

Spill Response & Cleanup:

The lift station was shut down and the sewage was removed from surface with a vacuum truck and surface soil was excavated and disposed of as HAZMAT.

Corrective Measures

Daily inspections were conducted at the lift station prior to receiving new parts to be installed. New flexible piping has been installed to prevent re-occurrence. Figures 1 and 2 show the flexible pipe installed and insulation of the piping that continues outside, respectively.

Figure 1: Newly installed flexible hose.

Figure 2: Insulated piping outside the MSB sewage lift station.

On September 20, 2018 during a site inspection with INAC and ECCC personnel, a spill was observed at three separate tanks (100,000 L tanks) used for treated sewage sludge storage. The storage tanks are located at the old fuel farm used under Licence 2BB-MEL1424 and is 219 m and 394 m up-gradient (0.91% 2.3%, receptively) from Lake J5 and Lake H20, respectively. Based on the distance, gradients and mine infrastructure located between the spill and the Lakes, migration of the spill material is not anticipated to meet any water bodies.

The spill is being reported as per NWB Licence 2BB-MEL1424, Part H, item 4.
The spill removal and cleanup is planned and follow up report will be issued.

Follow Up Report: #18-396
September 20, 2018 Treated Sewage Sludge

Description of Incident:

On September 20, 2018 during a site inspection with INAC and ECCC personnel, a spill was observed at a storage tank (100,000 L tanks) used for treated sewage sludge storage. The spill occurred at one tank during filling, however, overspray was observed on two adjacent storage tanks. The storage tanks are located at the old fuel farm used under Licence 2BB-MEL1424 and is 219 m and 394 m up-gradient (0.91% 2.3%, receptively) from Lake J5 and Lake H20, respectively. Based on the distance, gradients and mine infrastructure located between the spill and the Lakes, migration of the spill material is not anticipated to meet any water bodies.

Spill Response & Cleanup:

On the day of the spill observation, the ground froze and it snowed during the evening. Personnel were unable to excavate the material with a hand-shovel. Since the tanks are filled, the tanks cannot be mobilized to improve access for heavy equipment, until emptied. It is Agnico Eagle's intent is to empty the tanks and to discharge the material to the dry-stack tailings storage facility when operational (in compliance with the sludge disposal planning). The timeframe to have the tanks emptied is not defined at the moment.

Spill Cause and Corrective Measures

The spill was caused by human error and miscommunication between the pump operator and the person filling the tank with the treated sewage sludge. Spill reporting procedures have been reviewed with the personnel involved, since the procedure to report was not followed. Additionally, a procedure has been modified for the discharge of effluent to a storage tank. This procedure has been delivered to personnel and will continue to be communicated. The spill located under the storage tank will be excavated (by hand shovel or with heavy equipment) and disposed of as HAZMAT once the ground is thawed and prior to freshet to mitigate transport migration with surface flow.

While loading fuel truck, excess volume of fuel was programmed to be loaded into the truck, causing an overflow of diesel. Upon seeing the overflow operator immediately hit the kill switch, stopping flow of fuel. No water body were impacted by the spill and contaminated material will be send to the landfarm.

A follow up report will be issued.

Follow Up Report: #18-417
October 4th, 2018 Diesel fuel

Description of Incident:

On October 4th, while loading the fuel truck, excess volume of fuel was programmed to be loaded into the truck causing an overflow of Diesel. The fuel truck operator took a first dip and set the load to 8500L for the first sequence. The operator than carried out for the second sequence and reset a second load of 8500L without taking a second dip. The tanker started to overflow near the end of the second sequence.

The first estimation (400L) was a visual one during clean up to report as soon as possible the spill to the authority. During the investigation, the amount was corrected according to facts. A dip was performed prior to the first sequence showing 2800L remaining in the tanker. Two sequence of 8500L were set and 29L was left from the second sequence when the operator hit the emergency stop button. The fuel tank capacity is 18 927L which lead us towards a 844L spill

Spill Response & Cleanup:

As soon as the operator saw the overflow, he pressed the emergency stop button and called his supervisor. The supervisor immediately dispatched a grader and a loader for cleanup. Berms were established and absorbent pads deployed. The excess fuel was pumped to another truck. The grader and the loader began scrapping the surface material. Clean up efforts continued the next day, with an excavator excavating the contaminated material (10 to 12 inches deep). Approximately 20m3 of contaminated soil was taken to the landfarm A. Readings at the excavated site were taken following the completion of excavation with a MiniRAE Lite instrument. The values were below 25ppm and as such are deemed decontaminated.

Spill Cause and Corrective Measures

It was found during the investigation process that the spill was caused by human error. The operator didn't follow the procedure for which he was trained and didn't carry out a second dip before setting the load for the second sequence. Also, no spotter was use while fueling the tanker. For the corrective measures, the supervisor will meet with all employees to review procedure and discuss criticality of being sure to follow all step of fuel loading procedure. A warning system for fuel truck will be installed for high level alarm. A secondary containment will be built in this area in 2019.

On October 30th, 2018, a worker called E.I. supervisor regarding water coming out of the main camp lift station. Upon arrival, the system got shut down and material was put to contain the spill. The vaccum truck was use to remove extra liquid and the contaminated material was scrapped and will be disposed properly.

No water body was impacted by the spill, the closer water body is over 250 meters.
A follow up report will be issued.

The spill is being reported as per NWB Licence 2AM-MEL1631 Part H, item 8.

AGNICO EAGLE
MELIADINE

Follow Up Report: #18-440
October 30th, 2018 Lift Station Sewage Spill

Description of Incident:

On October 30th, pump #1 of the main lift station failed, causing untreated sewage to begin spilling out onto the gravel pad a few meters west of the main entrance of the camp. The current design of the lift station wiring works in such a way that when one pump goes into failure mode, the circuitry shuts off both pumps. Consequently, both pumps shut off within the effluent storage tank and it overfilled, resulting in sewage being released onto the ground.

Spill Response & Cleanup:

Initially, an employee who was outside at the time noticed the water flowing and called the E&I supervisor over the radio. The system was then shut down and E&I began using gravel to contain/absorb the spill, and a vacuum truck to remove as much standing water as possible. Peat moss was then used to further absorb any more saturated ground and was left to sit overnight.

The following day the contaminated material was scraped up with a loader and brought to the License A Landfarm (approximately 6m^3), and will later be spread over existing windrows to enhance the bio-remediation process. INAC was first contacted to ensure that this was a suitable plan of action for disposing of the sewage-contaminated material.

Spill Cause and Corrective Measures

An investigation was completed and the cause of the spill was determined to be a failed pump, which lead to an overflow of the effluent storage tank. A new pump is being brought in on a rush order to replace the broken one. The system's circuitry will be reconfigured so that when one pump fails, the other will remain operating. An alarm horn will be added to warn of high levels in the storage tank, and will send a signal advising central control.

Photo 1: Panorama showing the extent of the affected area.

Photo 2: Peat moss applied to contaminated area to absorb material.

Photo 3: Excavation of the contaminated material.

Photo 4: Contaminated material brought to the License A Landfarm (the dark material).

Due to a hole in a Sea-Can door and freezing of a hose and valve at the outlet of the Exploration STP retention tank, the retention tank could not be emptied, causing a spill from an overflow at the top of the tank. Following the overflow, water to the Exploration Camp was temporarily shut down, the hose and valve was thawed and the retention tank was emptied. As a preventative measure, a plywood door with insulation applied was installed to the Sea-Can to prevent freezing in the future. Treated water was frozen in place below the Mel-7 pipeline. The spilled water will be removed with ice picks and transported to CP1. The last Mel-7 results pertaining to the November 5th sample date showed a fecal coliforms concentration of <2 CFU/100ml and a total coliform concentration of <10 CFU/100ml. Results of November 12th & November 19th sampling events will be supplied in the follow-up report.

This spill is being reported as per part H, item 4 of the 2BB-MEL1424 Water Licence.

Follow Up Report: #18-455
November 17, 2018 Retention Tank Overflow

Description of Incident:

Due to freezing of an outlet hose and valve at the Exploration Camp Sewage Treatment Plant retention tank, the retention tank could not be emptied. The tank overflowed treated sewage effluent within the Sea-can housing and made contact with the ground via a hole in the door. The flow extended less than 5m from the spill source and the nearest water body, Meliadine Lake is approximately 78m from the source.

Spill Response & Cleanup:

Following the overflow, water to the Exploration Camp was temporarily shut down, the hose and valve was thawed and the retention tank was emptied. Treated effluent was frozen in place beneath the Mel-7 pipeline. The material was removed with ice picks and transported to CP1.

Spill Cause and Corrective Measures

The Sea-Can containing the retention tank had shifted in such a way that the door was not able to be closed completely, and had been left slightly ajar. Although a heater runs inside the Sea-Can, the outside temperature was less than -30°C, which led to the freezing of the hose and valve. As a preventative measure, an insulated plywood door was installed on the Sea-Can so that it can be closed completely and prevent freezing in the future.

Treated water at this location is sampled and tested weekly (MEL-7 sampling location). At the time of the spill, the most recent results were that of the November 5th sample, which indicated a fecal coliform level of <2 CFU/100ml reported in the original spill report. Following the spill, two further sets of results showed all parameters were well below the former Type B (1424) water license discharge limits (Table 1).

Table 1: Results of lab analysis from MEL-7 treated effluent and corresponding license discharge limits.

Parameter	Type B 1424 License Limits	2018-11-05 Results	2018-11-12 Results	2018-11-19 Results
pH	**6.0 to 9.5**	6.91	7.08	7.61

Due to failure of an expansion joint on the boiler recirculation system, approximately 200L of water with corrosion inhibitor (Drewgard 4109) spilled to ground. The water froze 8m3 of snow mixed with spilled material was taken to P3, a containment pond with the sites managed water system. Last analysis of Drewgard concentration was 0.195ppm. No water body was impacted. The nearest body of water is >300m away.

Follow Up Report: #18-477
December 11, 2018 Boiler Recirculation Loop Leak

Description of Incident:

Due to failure of an expansion joint on the boiler recirculation system, approximately 200L of water with corrosion inhibitor (Drewgard 4109) spilled to ground. The coordinates of the spill were, 63° 2'19.52"N, 92°13'39.97"W. The water froze and 8m^3 of snow and ice was transferred to P3, a containment pond within the site's managed water system. Most recently analyzed at 0.195ppm. No water body was impacted. The nearest body of water is >300m away.

Spill Response & Cleanup:

Site personnel shut off values preventing further release of water from the boiler recirculation system. Water followed through the floor of the Arctic corridor to ground and froze. Frozen water from the system was cleaned up with heavy equipment. Material was transported and contained in P3, part of the site’s water management system. A sample of the boiler system water was collected for analysis.

Spill Cause and Corrective Measures

The release occurred due to the failure of an expansion joint in the boiler recirculation system. The cause of the failed component is unknown. The expansion joint was replaced and the system inspected for leaks.

Plain Language Summary

Overview

The Meliadine Gold Mine (Mine) is located in the Kivalliq District of Nunavut near the western shore of Hudson Bay, in Northern Canada, approximately 25 km north of Rankin Inlet. Pre-construction activities were completed at the Mine between January 2015 and June 2017, and construction activities were initiated in July 2017. Dewatering of Lake H17 occurred in August to October 2016 to create Collection Pond 1 (CP1), with dewatering effluent discharged into the narrows between the east and west/south basins of Meliadine Lake. The first mine effluent discharge through the permanent diffuser (CP1 diffuser) into the east basin of Meliadine Lake occurred from June to September 2018.

Upon the discharge of dewatering effluent to Meliadine Lake, the Mine became subject to the Metal and Diamond Mining Effluent Regulations (MDMER). Under the MDMER, the Mine is required to conduct Environmental Effects Monitoring (EEM) studies, the results of which are used by Environment and Climate Change Canada (ECCC) to assess the effectiveness of the effluent regulations by evaluating effects on fish, fish habitat, and use of fisheries resources by humans.

The original objective of the Cycle 1 EEM study was to assess the effect of the dewatering discharge from Lake H17 on the benthic invertebrate community and fish population health in Meliadine Lake. In their comments on the EEM study design, the ECCC recommended that the EEM Near-field exposure area be relocated to better capture the effects of effluent release from the new permanent CP1 diffuser, which became operational in 2018. Therefore, the EEM Near-field area was relocated and is now aligned with the AEMP Near-field area. A plume delineation study was also conducted during the discharge period to describe effluent mixing in the Near-field area. The biological monitoring studies in 2018 included a benthic invertebrate community survey and a small-bodied fish health survey, with supporting water and sediment quality data collection.

The Aquatic Effects Monitoring Program (AEMP) is a requirement of the Type A Water Licence (2AM-MEL-1631, Part I, Item 3). The AEMP is intended to function as an integrated monitoring program, which considers pathways to potential effects of the Mine on the aquatic environment, including changes in surface water quality, sediment quality, lower trophic communities, fish habitat, and fish health due to release of mine water, physical alteration of watersheds, and air emissions during construction, operations, and closure. The AEMP was also designed to incorporate EEM requirements of the MDMER throughout the life of the Mine, with supplemental components included to fulfill the additional conditions and requirements of the Water Licence. Beginning in 2018, the Cycle 1 EEM biological monitoring program was conducted concurrently with the AEMP.

There are two distinct programs in the AEMP for the Meliadine Mine: the Meliadine Lake study and the Peninsula Lakes study. The Meliadine Lake study was designed around the key aspects of the EEM program, with the study design for the benthic invertebrate community survey and the fish population health survey based on the EEM requirements. The core components of the Meliadine Lake study are water quality, sediment quality, benthic invertebrate community, and fish health and fish tissue chemistry. A targeted plankton study was also included to investigate the potential for plankton as a useful monitoring tool to support interpretation of potential Mine effects on the aquatic environment. Whereas the Cycle 1 EEM study included two sampling areas in Meliadine Lake: Near-field area and Reference Area 1, the AEMP includes two exposure areas (Near-field and Mid-field areas) and up to three reference areas (Reference Areas 1, 2, and 3). The Peninsula Lakes study was

designed to detect potential indirect effects from deposition of aerial emissions or alteration of watersheds. Water quality is the core component of the Peninsula Lakes study, with the intent to add biological studies if the water quality results suggest Mine-related changes have occurred.

Data and results presented in this report were collected as per the approved AEMP and Cycle 1 EEM study designs for the Mine. This report documents data collected in 2018, with a detailed evaluation of all data collected from 2015 to 2018, and was designed to address the reporting requirements for both the EEM and the AEMP. This is the first combined AEMP/EEM interpretive report for the Mine, and the first evaluation of effects since the CP1 diffuser became operational.

This report also presents normal ranges for water and sediment quality parameters, benthic invertebrate community variables and phytoplankton variables including chlorophyll *a*. The normal range is intended to estimate the range of natural spatial and temporal variability, and the more reference data incorporated into the calculation, the more accurate the estimate becomes. The normal ranges provided in this report are considered provisional due to the limited sample sizes used in the calculations for some components. These normal ranges may be re-defined in future reports to allow for the inclusion of additional monitoring data from the reference areas.

Mine Development Updates

The mine plan proposes open pit and underground mining methods for the development of the Tiriganiaq gold deposit, with two open pits (Tiriganiaq Pit 1 and Tiriganiaq Pit 2) and one underground mine.

Water management activities that occurred in 2018 included transporting treated sewage effluent to CP1 (starting in November 2017), and initiation of mine effluent discharge through the CP1 diffuser to Meliadine Lake in June 2018. Water quality monitoring associated with the final discharge point MEL-14 and the receiving environment monitoring station above the CP1 diffuser (i.e., MEL-13) was conducted during the discharge period. The new freshwater intake was installed in winter 2018.

Water Quality

In 2018, water quality sampling was conducted in Meliadine Lake once during the ice cover season (March) and twice in the open water season (July and August) from up to 25 stations across five sampling areas. Beginning in the open-water season, four new stations were added in the Near-field area and four historical stations were discontinued. New stations in the Near-field area were selected based on the location of the CP1 diffuser, which was installed and became operational in 2018. Water quality monitoring was scheduled for four times in 2018, but the September water quality program was cancelled due to unsafe conditions that prevented safe access to sampling stations. Three peninsula lakes (i.e., Lakes A8, B7, and D7) were sampled during the open-water season (July and August), at three stations per lake. This report provides a summary of the water quality monitoring programs completed in 2018 at Meliadine Lake and at the Peninsula Lakes, analysis of data collected between 2015 and 2018, and an interpretation of the results per the requirements of the AEMP and EEM.

In general, water quality in Meliadine Lake in 2018 was characterized as consistent in temperature through the water column, well oxygenated, neutral to alkaline, clear water, low specific conductivity, soft water, oligotrophic (very low in nutrients), and very low in metals. This characterization was similar to previous AEMP monitoring years (i.e., 2015 to 2017) and baseline (pre-2015). Water quality data were analyzed to determine if there were differences between the two exposure areas (i.e., Near-field and Mid-field), and the pooled reference areas of Meliadine Lake. Differences in water quality were observed in the Near-field area compared to the Mid-field and

reference areas for the open water season for several conventional parameters (e.g., specific conductivity, hardness, TDS, and turbidity), major ions, nutrients (total Kjeldahl nitrogen), organic carbon and several total metals. Similar patterns among areas were observed during ice-covered conditions. Similar spatial patterns were observed in previous AEMP monitoring years (e.g., 2016 and 2018); however, for specific conductivity, hardness and major ions the relative difference in concentrations of chloride, magnesium, and sodium among areas appears to have increased in 2018, relative to 2016 and 2017.

The analysis of the 2018 water quality results included a visual comparison of 2018 and 2017 construction phase data to pre-construction phase data (i.e., 2015 and 2016) in the Near-field area, alongside an evaluation of trends in the Mid-field and reference areas. Increasing trends in the Near-field area over time and relative to trends over time in the reference areas, were observed for specific conductivity, hardness, TDS, major ions, TOC, DOC, total metals (i.e., aluminum, barium, lithium, and strontium). Concentrations of these parameters also fell outside of the normal range for the Near field area. Normal ranges were calculated using data collected during baseline conditions (i.e., 1995 to 2013) and from reference areas (2015 to 2018). The normal range was also exceeded for several of these parameters in the Mid-field area. The observed changes in water quality suggest a Mine-related effect on water quality in the Near-field and Mid-field areas. However, the effect is within the range of conditions predicted by the Final Environmental Impact Statement (FEIS) for the Mine, and all parameters were well below Canadian Water Quality Guidelines (CWQG) for the protection of aquatic life.

Water quality in the Peninsula Lakes in 2018 was similar to water quality from previous AEMP monitoring years (i.e., 2015 to 2017). In these lakes, water quality is characterized as having consistent water temperature through the water column, being well oxygenated with neutral to alkaline pH, and oligotrophic to mesotrophic in trophic status (of low to moderate level of productivity). Concentrations of water quality parameters in Peninsula Lakes remained below CWQGs for all parameters. Water quality in the Peninsula Lakes was outside of the normal range for a number of total metals; however, water quality was generally consistent with FEIS predictions.

A visual analysis to evaluate potential changes in water quality over time was conducted for the Peninsula Lakes, with the purpose of comparing 2018 construction phase data to pre-construction phase data (i.e., 2016 to 2017). Increasing trends in each consecutive year were observed for reactive silica (Lake A8), dissolved phosphorus (Lake B7 and D7), total aluminum (Lake A8 and B7), arsenic (Lake A8), and molybdenum (Lake D7), relative to previous AEMP monitoring years. A step-increase in concentrations in 2018 (relative to previous AEMP monitoring years) was observed for total manganese (Lake A8 and D7), total boron, lithium, and strontium (Lake B7), and total vanadium (Lake B7 and D7). However, given the limited dataset, there is uncertainty associated with trend detection, and potential sources of the temporal trends are not identified in this report.

Sediment Quality

Sediment quality sampling was conducted in Meliadine Lake concurrently with benthic invertebrate sampling. Concentrations of arsenic, chromium, and copper exceeded the Canadian Sediment Quality Guidelines (SQG) in 2018, as also observed under baseline conditions. These guidelines include two categories: Interim Sediment Quality Guidelines (ISQG) and Probable Effect Levels (PEL). ISQG represent the concentrations below which adverse effects on benthic organism are expected to occur rarely, and PEL represents the concentrations above which adverse effects are probable. Comparisons to SQGs are used to assess the potential for adverse effects to aquatic biota, but do not indicate that actual effects may occur, because these guidelines apply Canada-wide and do not necessarily account for site-specific factors, such as the natural geology of the study area. Thus, guideline exceedances can be indicative of naturally elevated concentrations due to site-specific factors, and are not necessarily mine-related.

Specifically, arsenic concentrations in the Near-field area exceeded the ISQG and concentrations at four of the five stations also exceeded the PEL. For chromium and copper, sediments at all five Near-field stations were above the ISQGs but were below their respective PELs. In the Mid-field area, arsenic and copper concentrations exceeded ISQG at the five stations sampled in 2018 but did not exceed PEL. Chromium concentrations were also above the ISQG but below the PEL at four of the five stations sampled in the Mid-field Area. In Reference Area 1, only one out of five samples exceeded the ISQG for arsenic and chromium, whereas for copper concentrations at three of the five stations were above the ISQG. In Reference Area 3, ISQGs were exceeded at four of the five stations sampled for arsenic and three of the five stations for copper. Other than the above exceptions, concentrations of metals and metalloids at exposure and reference stations sampled in 2018 were below sediment quality guidelines.

As observed in previous years, the reference area sediments had significantly more sand and the Near-field area sediments had significantly more silt. As proportion of fine sediment in a sample can influence the total concentration of metals, the sediment chemistry data were normalized to the percent of fines before evaluation of statistical comparisons of areas of Meliadine Lake, and calculation of normal ranges for Meliadine Lake. Percentages of silt and sand did not differ significantly between the Mid-field and pooled reference areas.

Normalized arsenic concentrations were higher in the Near-field area compared to the pooled reference areas. Both Near-field and Mid-field areas had higher concentrations of normalized cadmium relative to the pooled reference areas. The Mid-field area had significantly higher total organic carbon relative to the other areas and had greater normalized concentrations of chromium and copper relative to the Near-field and pooled reference area concentrations.

Differences between exposure and reference areas were mainly associated with natural variability, which was also observed in 2015 and 2016, prior to the Mine effluent discharge. For metals above sediment quality guidelines in the Near-field area, concentrations in 2018 were lower than those reported under baseline conditions in 2015 and 2016.

Benthic Invertebrate Community

Benthic invertebrates are small animals with no backbones that live within sediments, or on the sediment surface, for all or part of their life cycles, and are an integral part of Arctic ecosystem food webs. In August 2018, benthic invertebrate community sampling was conducted in Meliadine Lake in the two exposure areas (Near-field and Mid-field), and two reference areas (Reference Area 1 and 3). Reference Area 2 was not sampled due to logistical and weather limitations. This report summarizes benthic invertebrate community data obtained in 2018, analyses the 2018 data and compares to data collected in 2015 and 2016, and interprets the results as per the requirements of the AEMP and EEM programs.

Because the Near-field and reference areas were found to have different substrates in previous sampling programs, a Sediment Reconnaissance Survey was conducted in July 2018 to further investigate suitable and comparable stations for future benthic invertebrate and sediment sampling. New stations were selected to maintain alignment with water quality, and to avoid excessive sampling effort in retrieving acceptable grab samples. Four new Near-field stations and two new Mid-field stations were selected for the 2018 sediment sampling program.

Meliadine Lake benthic invertebrate communities were reflective of typical subarctic communities and were characterized by low densities and low to moderate family-level richness. Communities were dominated by the midge family Chironomidae, with fingernail clams (Pisidiidae) subdominant. Snails (Gastropoda) were observed

in the Near-field area at higher proportions than in other areas, and amphipods were only present outside of the Near-field area, which likely reflects differences in habitat between the Near-field area and other sampling areas, as a result of taxon-specific habitat preferences.

To assess the potential impacts from the Mine effluent discharge for the Cycle 1 EEM study, EEM benthic invertebrate community comparisons were conducted at the family level to detect differences between the Near-field area and Reference Area 1. No statistically significant differences were identified between the Near field area and Reference Area 1 for the EEM effect endpoints and supporting endpoints evaluated in the EEM study.

The 2018 AEMP data analysis compared data collected from the two exposure areas to two reference areas through statistical and visual comparisons, to evaluate potential changes in benthic invertebrate communities due to changes in water and sediment quality. Comparisons were made at the lowest taxonomic level. A significant difference was found between sampling areas for total invertebrate density but not for total richness. Density was found to be significantly lower in the Near-field area compared to the pooled reference areas. No significant differences in density were detected between the Mid-field area and the pooled reference areas, or between the two reference areas. Total richness values were similar among the Near-field area, Mid-field area, and Reference Area 1; richness was higher in Reference Area 3. Total density was lower in the Near-field area compared to Reference Area 1, but both areas had similar family level richness. Comparisons between the Near-field area and Reference Area 1 showed higher diversity, evenness, and dissimilarity in the Near-field area. Differences in these endpoints between the two sampling areas likely reflect pre-discharge differences in habitat, particularly differences in sediment substrate composition. Sediments sampled from the Near-field area had a higher proportion of fines (i.e., silt + clay) and less sand compared to the Mid-field and Reference areas. Thus, spatial differences in particle size distribution between the Near-field area and other sampling areas have the potential to confound the ability of the AEMP and EEM study comparisons made to evaluate whether benthic invertebrate communities were impacted by the Mine effluent discharge in 2018.

Overall, the 2018 AEMP results indicate that benthic community has not been measurably affected by potential Mine-related changes in water and sediment quality in Meliadine Lake. Benthic invertebrate variables in the Near-field area were within their respective normal ranges. Statistical comparisons among areas did identify some significant differences between Near-field and reference areas, but these appeared to reflect pre-discharge differences in sediment composition among areas.

Fish Population Health

The 2018 fish health survey was performed to meet EEM requirements and evaluated the potential differences in indicators of fish health (e.g., energy storage, energy usage, and survival) between the exposure area of Meliadine Lake (i.e., the Near-field area) and one reference area (i.e., Reference Area 1), resulting from the development and operations of the Mine. It was not intended to meet the specific requirements of the Mine's AEMP fish health or fish tissue components, because it did not include a second reference area, a large-bodied sentinel species (i.e., Lake Trout [*Salvelinus namaycush*) or a fish tissue chemistry component (as neither mercury or selenium concentrations in the mine effluent triggered a fish tissue study under the MDMER). Fish health and tissue chemistry sampling for the AEMP is currently scheduled for 2021.

Threespine Stickleback (*Gasterosteus aculeatus*) from the Near-field area were generally larger than those collected from Reference Area 1. Female Threespine Stickleback sampled from the Near-field area had greater condition than individuals sampled from Reference Area 1, which means that female fish from the Near-field area had higher body weight while adjusting for length of the fish. This finding suggests fish from the Near-field area

had increased energy storage; however, the magnitude of difference (i.e., 6%) was below the CES of 10%. A similar response was not observed in supporting energy storage endpoints (i.e., relative liver weight and relative egg weight). Statistical power was low for age and gonad weight comparisons, as age was not a strong predictor of fish size. Threespine Stickleback were encountered at multiple reproductive stages during sampling, which resulted in greater variability within the dataset.

The majority of Threespine Stickleback captured were infected by a tapeworm that competes with the host for available resources and decreases the energy allocated to storage and spawning. This represents a complicating factor that needs to be considered in the design and interpretation of future fish health and fish tissue monitoring programs.

Plankton

Plankton are small organisms that live suspended in the water column. Phytoplankton are small, free-floating algae and zooplankton are small, sometimes microscopic, animals (crustaceans) that eat algae.

Plankton monitoring was conducted as a targeted study in Meliadine Lake to characterize baseline conditions for the plankton community and to evaluate the usefulness of plankton as a potential long-term monitoring tool. Prior to the 2018 sampling program, the plankton study included sampling and analysis of depth-integrated nutrients, chlorophyll *a*, phytoplankton, and zooplankton over three years in Meliadine Lake (2015, 2016, and 2017) and two years in the Peninsula Lakes (2015 and 2016). Nutrients included total nitrogen (TN), total phosphorus (TP), nitrate, nitrite, ammonia, and orthophosphate. “Depth-integrated” means that nutrients were analyzied in a water sample that included water collected throughout the water column where plankton live.

Based on the data collected in 2017, it was determined that the phytoplankton dataset (i.e., chlorophyll *a*, and phytoplankton abundance, biomass, and composition of major taxonomic groups, along with supporting nutrient data collection) should be carried forward to future years for Meliadine Lake to further evaluate its usefulness as a monitoring tool. As a result, phytoplankton sampling during the summer season was carried forward for 2018 to evaluate potential changes in key monitoring endpoints (abundance, biomass, community composition) and to provide an indication of potential changes to trophic status in the lake. This report provides a summary of plankton data collected during the summer 2018 phytoplankton sampling program in Meliadine Lake, with a comparison against data collected during summer sampling events during the pre-construction and construction phases of the Mine (2015 through 2017). Phytoplankton sampling stations for 2018 were aligned with water quality stations, including those adopted in 2018.

Concentrations of most depth integrated nutrients were generally low in 2018 and consistent with concentrations observed in previous years (i.e., 2015 to 2017). The mean concentration of TN in the Near-field area was slightly higher than in previous years. Concentrations of TP in 2018 were generally above detection limits but were low and consistent with TP concentrations observed previously. Concentrations of nitrate, nitrite, ammonia, and orthophosphate were below detection limits in the majority of samples collected in 2018, consistent with previous years. Chlorophyll *a* concentrations in Meliadine Lake followed a similar spatial trend in 2018 as observed in previous years, with higher concentrations in the Near-field area than in the Mid-field and reference areas. Chlorophyll *a* concentrations had a significant, weak to moderately strong linear relationship with phytoplankton biomass. Given this relationship, the current results suggest chlorophyll *a* is a useful indicator of phytoplankton biomass in Meliadine Lake.

Higher phytoplankton abundance and biomass were observed in the Near-field area compared to other areas. Abundance, but not biomass, was higher in the Near-field area in 2018 than in previous years. Spatial trends were consistent with previous years; however, higher variability was observed among years in the reference areas with the inclusion of the 2018 data, which interfered with the evaluation of spatial trends in the phytoplankton community.

Based on the August phytoplankton dataset collected from Meliadine Lake since 2015, late-summer phytoplankton monitoring is considered a useful monitoring tool for Meliadine Lake to detect potential effects resulting from nutrient enrichment.

Conclusions

Results of the harmonized 2018 Cycle 1 EEM/AEMP study indicate that the Mine discharge to Meliadine Lake through the permanent diffuser (CP1 diffuser) has resulted in measurable effects on water quality and phytoplankton community, but no effects attributable to the Mine discharge were apparent on sediment quality, benthic invertebrates and small-bodied fish. The type of effect observed on water quality consisted of increased concentrations of TDS, major ions, nutrients, organic carbon and several total metals in the Near-field area compared to the reference areas. Concentrations of these parameters fell outside of the normal range, but remained well below Canadian Water Quality Guidelines (CWQG) for the protection of aquatic life. The observed effects were within the range of conditions predicted by the FEIS for the Mine. A mild enrichment effect was detected on phytoplankton in the Near-field area, as well as a spatial trend of decreasing primary productivity with increasing distance form the Mine discharge. No Mine-related effects were detected in the peninsula lakes.

Comparison of the 2018 water quality and benthic invertebrate results to Low Action Levels resulted in no Action Levels being triggered for toxicological impairment or nutrient enrichment.

Study Limitations

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by Golder for the sole benefit of Agnico Eagle Mines Limited (Agnico Eagle). It represents Golder's professional judgement based on the knowledge and information available at the time of completion. Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to Golder by Agnico Eagle, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by Golder are considered its professional work product and shall remain the copyright property of Golder. Agnico Eagle may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

Acknowledgements

Golder would like to acknowledge the support of Agnico Eagle (Martin Theriault, Jessica Huza) during the execution of the field program and preparation of this report. During the field programs, Agnico Eagle provided on-the-ground logistic support, provision of workspace, and provision of field personnel. In particular, Golder would like to recognize field and logistical support from Agnico Eagle (Dan Gorton, Jennifer Brown, Laura Sue Hanson, Justin MacMillan, Randy Schwandt, Sean Arruda) and Golder (Brian Linglebach, Kia Marin, Mike Hildebrand, Jarett Nevill, Carol Zastavniouk, Jaimie Weir).

Inuit involvement in monitoring included the following:

- Louis Ulayok for the first few months of 2018
- Peter Naitok for two weeks during the AEMP
- John Papak on though Sarliaq for a week or two during the EEM
- Other Inuit workers through Golder Nuqsana

The following people contributed to this report as primary authors or senior reviewers:

- Lindsey Felix, Ph.D. (Golder: Introduction, Site Characterization, Summary of Previous Biological Monitoring Studies, Study Design Overview, Supporting Environmental Data)
- Charity Beres, B.Sc. (Golder: Senior review of Introduction, Site Characterization)

s	seconds
“	
tpd	tonnes per day
y/yr	years

1.0 INTRODUCTION

The Meliadine Gold Mine (Mine) is located in the Kivalliq District of Nunavut near the western shore of Hudson Bay in Northern Canada (Figure 1.1-1) and is owned by Agnico Eagle Mines Limited (Agnico Eagle). The Mine is located within the Meliadine Lake watershed of the Wilson Water Management Area (Nunavut Water Regulations Schedule 4). The nearest community is Rankin Inlet (coordinates: 62°48'35''N; 092°05'58''W), which is approximately 25 km south of the Mine (coordinates: 63°01'03''N, 92°12'03''W).

The Mine is required to conduct aquatic monitoring under both federal and provincial legislation. This report documents the aquatic receiving environment monitoring activities as required by the Metal and Diamond Mining Effluent Regulations (MDMER; Government of Canada 2018) and the Type A Water Licence (2AM-MEL1631) (NWB 2016). These activities include the Environmental Effects Monitoring (EEM) program under the MDMER, and the Aquatic Effects Monitoring Program (AEMP) under the Water Licence. In 2018, the Cycle 1 EEM biological monitoring was conducted concurrently with the AEMP.

1.1 Background

1.1.1 EEM

The MDMER permits the deposit of mine effluent under certain conditions: 1) the effluent pH must be within a defined range, 2) the concentrations of deleterious substances must not exceed authorized limits as defined in the MDMER, and 3) the effluent must not be acutely lethal to rainbow trout. Mines that are subject to the MDMER are required to conduct EEM studies, the results of which are used by Environment and Climate Change Canada (ECCC) to assess the effectiveness of the effluent regulations by evaluating effects on fish, fish habitat, and use of fisheries resources by humans.

Effluent was discharged to Meliadine Lake from August to October 2016 during the dewatering of Lake H17, which triggered the Mine to be subject to the MDMER due to the volume of dewatering effluent discharged (i.e., more than 50 m^3/day). This discharge occurred through the discharge point MEL-D-1 into Meliadine Lake. The dewatering infrastructure was dismantled in October 2016 and a new diffuser was constructed in 2017 at a different location on Meliadine Lake, which will function as the permanent discharge structure for effluent discharge from the Mine. As per the MDMER, the first EEM study design was submitted to ECCC in August 2017, with the intention of conducting the required biological monitoring studies in August 2018 (Golder 2017a). Biological study components included benthic invertebrate community (BIC) survey and fish population survey, with supporting water and sediment quality.

1.1.2 AEMP

The AEMP is an annual requirement of the Type A Water Licence (2AM-MEL-1631; NWB 2016) and has been designed to function as an integrated monitoring program, which considers pathways to potential effects of the Mine on the aquatic environment (Golder 2016a). The AEMP was developed through consultation with communities, stakeholders, and regulatory authorities, and includes incorporation of Inuit Qaujimajatuqangit (IQ), plus scientific knowledge of aquatic ecosystems. The AEMP design incorporates EEM requirements of the MDMER throughout the life of the Mine, with supplemental components included to fulfill the additional conditions and requirements of the Water Licence (NWB 2016). The AEMP considers changes in surface water quality, sediment quality, lower trophic communities, fish habitat, and fish health due to release of Mine water, physical alteration of watersheds, and air emissions during construction, operations, and closure. The AEMP was also designed to provide an early warning system, whereby the results of aquatic monitoring are used to reduce or

prevent adverse environmental effects through a Response Framework and evaluation of the monitoring program at regular intervals.

As per the AEMP Design Plan, water quality monitoring in Meliadine Lake and the Peninsula lakes is an annual program, and monitoring of sediment quality, BIC, and fish health and fish tissue has been moved to the EEM schedule, because pre-operations data have been collected. The 2018 study components included water quality in Meliadine Lake and selected peninsula lakes (i.e., Lakes A8, B7, and D7), and sediment quality and BIC in Meliadine Lake. A special study on plankton was also conducted in Meliadine Lake to continue evaluating the usefulness of plankton as a monitoring tool for the AEMP.

1.2 Objectives

The focus of this report is to evaluate the effects of the Mine on the aquatic receiving environment in Meliadine Lake under the current Water Licence 2AM-MEL-1631 (NWB 2016).

1.2.1 EEM

The original objective of the Cycle 1 EEM study was to assess the effect of the dewatering discharge form Lake H17 on the BIC and fish population health in Meliadine Lake. As such, the Cycle 1 EEM Study Design proposed that the exposure area for the EEM be located within the vicinity of MEL-D-1 (Golder 2017a). In their comments on the study design, ECCC recommended that the exposure area be relocated to assess the effects of the mine effluent discharge from the permanent discharge point (MEL-14) instead of the dewatering discharge (ECCC 2018). This recommendation considered that dewatering discharge from MEL-D-1 would have occurred two years before the 2018 biological monitoring study and that the effluent discharged from MEL-14 starting in 2018 would be a more concentrated effluent with a higher potential for adverse effects on the receiving environment. Therefore, the EEM Near-field exposure area was relocated to better capture the effects of effluent release from MEL-14 and is aligned with the AEMP Near-field area.

The Cycle 1 EEM study design was reviewed by the Technical Advisory Panel (TAP), which consisted of representatives from ECCC, Nunavut Water Board (NWB), and Indigenous and Northern Affairs Canada (INAC). Other recommendations and requirements identified by the TAP following their review of the Cycle 1 EEM study design (ECCC 2018) were addressed and incorporated into the Cycle 1 EEM Study and into this first interpretative report.

This report presents the results of the Cycle 1 EEM study, which consisted of the following components:

- effluent and water quality monitoring
- effluent sublethal toxicity testing
- a BIC survey
- a lethal small-bodied fish survey

In addition to describing the methods and results of each of the EEM study components, this report provides an interpretation of those results with regards to potentially Mine-related effects. The study design (Golder 2017a) and the implementation of the field survey and data analysis followed, where appropriate, the guidance and recommendations provided in the Metal Mining EEM Technical Guidance Document (TGD; Environment Canada 2012).

1.2.2 AEMP

The overall objective of the AEMP is to assess potential Mine-related effects on the aquatic ecosystem and to meet regulatory requirements outlined in the Type A Water Licence (2AM-MEL1631; NWB 2016) while also meeting commitments made during the environmental permitting process (see Table 1-1 in the AEMP Design Plan [Golder 2016a]). In addition, the AEMP was designed to meet the MDMER requirements.

The specific objectives of the AEMP for the Mine are as follows:

- to determine the short- and long-term effects of the Mine on the aquatic receiving environment;

- to evaluate the accuracy of predictions made in the Final Environmental Impact Statement (FEIS; Golder 2014a), including the final significance statements regarding impact to the aquatic ecosystem;
- to assess the efficacy of planned mitigation incorporated into the Project design; and
- to collect data required to identify the need for potential additional mitigation of Project effects within a management response framework.

The specific objectives of this report were to document 2018 data collection and detailed analyses for the core components of the AEMP that were sampled in 2018 (i.e., water quality, sediment quality, and BIC), and to present the findings of the special study on plankton community monitoring. This report also includes a comparison of previous data collected during the construction phase of the Mine (2015 through 2017). Recommendations and requirements identified by ECCC, INAC, and Kivalliq Inuit Association (KIA) following their review of the 2017 AEMP Annual Report were addressed and incorporated into the the 2018 AEMP study and this report.

1.3 Structure of Report

This report presents the results of both the Cycle 1 EEM and the 2018 annual AEMP. This combined EEM/AEMP report also includes an updated summary of data collected in 2015 to 2017 for water quality. The document is organized as follows:

- Executive Summary
- Acknowledgements
- Introduction (Section 1)
- Site Characterization (Section 2)
- Summary of Previous Biological Monitoring Studies (Section 3)
- Study Design Overview (Section 4)
- Supporting Environmental Data (Section 5)
- Water Quality – Meliadine Lake (Section 6)
- Water Quality – Peninsula Lakes (Section 7)
- Sediment Quality (Section 8)
- Benthic Invertebrate Community (Section 9)
- Fish Health (Section 10)
- Plankton Targeted Study (Section 11)
- Overall Summary and Conclusions (Section 12)

1.4 Concordance Table

The report was designed to clearly address the reporting requirements of both the EEM and the AEMP. To failitate the review process, a concordance table is provided to cross-reference EEM requirements and AEMP commitments with the appropriate report section number (Table 1.4-1).

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
EEM Requirement[(a)]		
12(1)(a)	a description of any deviation from the study design that occurred while the biological monitoring studies were being conducted and any impact that the deviation had on the studies;	Study Design Overview, Section 4.1, Table 4.1-1 Water Quality, Section 6.2.1 Sediment Quality, Section 8.2.1 Benthic Invertebrate Community, Section 9.2.1 Fish Health, Section 10.2
12(1)(b)	the latitude and longitude of sampling areas and a description of the sampling areas sufficient to identify the location of the sampling areas;	Site Characterization, Section 2.5, Table 2.5-1 Water Quality, Section 6.2.2.1, Table 6.2-1 Sediment Quality, Section 8.2.2.1, Table 8.2-1 Benthic Invertebrate Community, Section 9.2.1, Table 9.2-1 Fish Health, Appendix 10A
12(1)(c)	the dates and times when samples were collected;	Water Quality, Table 6.2-1, Appendix 6D Sediment Quality, Table 8.2-1, Appendix 8B Benthic Invertebrate Community, Table 9-1 Fish Health, Appendix 10A
12(1)(d)	the sample sizes;	Water Quality, Section 6.4.2.1, Table 6.4-3 and Table 6.4-5 Sediment Quality, Section 8.4.2.1, Table 8.4-5 Benthic Invertebrate Community, Section 9.2.2 Fish Health, Sections 10.4.2 and 10.4.3
12(1)(e)	the mean, median, standard deviation, standard error and minimum and maximum values in the sampling areas	Water Quality, Section 6.4.2.1, Table 6.4-3 and Table 6.4-5 Sediment Quality, Table 8.4-5 Benthic Invertebrate Community, Appendix 9D Fish Health, Table 10.4-3 and 10.4-6
12(1)(e)(i)	in the case of the study respecting fish population, effect indicators of growth, reproduction, condition and survival that include, if practicable, the length, total body weight and age of the fish, the weight of its liver or hepatopancreas and, if the fish are sexually mature, the egg weight, fecundity and gonad weight of the fish	Fish Health, Table 10.4-3 and 10.4-6

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
12(1)(e)(ii)	in the case of the study respecting the benthic invertebrate community, effect indicators of the total benthic invertebrate density, evenness index, taxa richness and, if the study is conducted in an area where it is possible to sample sediment, total organic carbon content of sediment and particle size distribution of sediment	Benthic Invertebrate Community, Appendix 9D
12(1)(e)(iii)	in the case of the study respecting fish tissue mercury, the effect indicator of the concentration of total mercury (wet weight) in the fish tissue	Not applicable. See Study Design Overview, Section 4.1
12(1)(e)(iv)	in the case of the study respecting fish tissue selenium, the concentration — in the muscle or whole body and, if practicable, in the ovaries or eggs — of total selenium (dry weight) reported in µg/g and the percentage of the moisture content of the sample	Not applicable. See Study Design Overview, Section 4.1
12(1)(f)	in the case of the study respecting the benthic invertebrate community, a calculation of the similarity index effect indicator	Benthic Invertebrate Community, Table 9-5 and Appendix 9D
12(1)(g)	an identification of the sex of the fish sampled and of the presence of any lesions, tumours, parasites or other abnormalities and, in the case of the study respecting fish tissue selenium, the type of fish tissue studied and the scientific rationale for the selection of that tissue	Fish Health, Appendix 10B, Table 10B-3 and Table 10B-5
12(1)(h)	a determination as to whether there is a statistically significant difference between the sampling areas for the calculations under subparagraphs (e)(i) to (iii) and paragraph (f) taking into consideration the information identified under paragraph (g), with the statistical comparison made separately and independently for each effect indicator	Benthic Invertebrate Community, Table 9-6 Fish Health, Section 10.4, Table 10.4-4 and Table 10.4-7
12(1)(i)	a statistical analysis of the results of the calculations under subparagraphs (e)(i) to (iii) and paragraph (g) that indicates the probability of correctly detecting an effect of a pre-defined size and the degree of confidence that can be placed in the calculations	Benthic Invertebrate Community, Table 9-5 Fish Health, Section 10.4, Table 10.4-4 and Table 10.4-7
12(1)(j)	for an effect indicator referred to in paragraph (e) with an assigned critical effect size, a comparison of the magnitude of the effect — calculated in accordance with subsection (2) or (3), as the case may be — to its critical effect size	Benthic Invertebrate Community, Table 9-5 Fish Health, Section 10.4, Table 10.4-4 and Table 10.4-7

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
12(1)(k)	any supporting data, including raw data, for the information provided under paragraphs (e) to (j)	Benthic Invertebrate Community, Section 9.4.1, Section 9.4.2.1, and Appendix 9D Fish Health, Appendix 10A, Appendix 10B
12(1)(l)	a description of any quality assurance or quality control measures that were implemented and the data related to the implementation of those measures	Water Quality, Section 6.3, Appendix 6A Sediment Quality, Section 8.3, Appendix 8A Benthic Invertebrate Community, Section 9.3 and Appendix 9C Fish Health, Section 10.3 and Appendix 10B
12(1)(m)	based on the information referred to in paragraphs (e) to (k), the identification of	-
12(1)(m)(i)	any effect on the fish population	Fish Health, Section 10.5, Table 10.5-1 and Table 10.5-2
12(1)(m)(ii)	any effect on the benthic invertebrate community	Benthic Invertebrate Community, Section 9.4.2.1, Section 9.5.1 and Appendix 9D
12(1)(m)(iii)	any effect on fish tissue from mercury	Not applicable. See Study Design Overview, Section 4.1
12(1)(n)	for an effect indicator with an assigned critical effect size, a statement as to whether the absolute value of the magnitude of the effect is equal to or greater than the absolute value of its critical effect size	Benthic Invertebrate Community, not applicable, Table 9-5 Fish Health, not applicable, Section 10.5
12(1)(o)	a summary of the results of effluent characterization, sublethal toxicity testing and water quality monitoring reported under paragraph 8(e) beginning on the day on which the mine becomes subject to section 7 of these Regulations	Overall Summary and Conclusions, Section 12.1
12(1)(p)	the conclusions of the biological monitoring studies, and a description of how those conclusions will impact the study design for subsequent biological monitoring studies, taking into account	Overall Summary and Conclusions, Section 12.1
12(1)(p)(i)	the results of any studies referred to in paragraph 10(f)	Summary of Previous Biological Monitoring Studies, Section 3.0
12(1)(p)(ii)	the presence of anthropogenic, natural or other factors that are not related to the effluent under study and that may reasonably be expected to contribute to any observed effect	Site Characterization, Section 2.6
12(1)(p)(iii)	the results of the statistical analysis conducted under paragraphs (h) and (i)	Benthic Invertebrate Community, Table 9-5 and Table 9-6 Fish Health, Section 10.4, Table 10.4-4 and Table 10.4-7

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
12(1)(p)(iv)	the data referred to in paragraph (l)	Water Quality, Appendix 6A Sediment Quality, Appendix 8A Benthic Invertebrate Community, Appendix 9C Fish Health, Appendix 10B
12(1)(q)	the month in which the next biological monitoring studies will start, if any biological monitoring studies are required	Overall Summary and Conclusions, Section 12.3.1
12(1)(r)	the date when the next interpretative report is required to be submitted or would be required to be submitted but for the application of subsection 16(3)	Overall Summary and Conclusions, Section 12.3.1
12(2)	For the purpose of the study respecting fish population, the magnitude of the effect for an effect indicator is to be calculated using the following formula: (A – B)/B × 100 where A is (a) for the purpose of the age indicator, the mean value for the indicator in the exposure area, and (b) for the purpose of the indicators other than age, the adjusted mean value — obtained using the analysis of covariance (ANCOVA) statistical test method — for the indicator in the exposure area; and B is (a) for the purpose of the age indicator, the mean value for the indicator in the reference area, and (b) for the purpose of the indicators other than age, the adjusted mean value — obtained using the analysis of covariance (ANCOVA) statistical test method — for the indicator in the reference area.	Fish Health, Section 10.2.6

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
12(3)	For the purposes of the study respecting the benthic invertebrate community, the magnitude of the effect for an effect indicator is to be calculated using the following formula: (A – B)/C where A is the mean value for the indicator in the exposure area; B is the mean value for the indicator in the reference area; and C is the standard deviation for the indicator in the reference area.	Benthic Invertebrate Community, Section 9.2.4.5.2 and Table 9-5
AEMP Commitment[(b)]		
KIA 18 and 26	For the 2018 AEMP Annual Report, baseline and pre-construction statistics will be recalculated for the Near-field area, open-water conditions, using data from 2015 and 2016 only; statistics for the other areas will not be recalculated as all data used represent baseline conditions.	Water Quality, Appendix 6H
KIA 19	For the 2018 AEMP Annual Report, data from 1997, 1998, and 2008 will be reviewed and it will be determined if they should be included in the calculation of Normal Ranges of open-water and under-ice conditions in Meliadine Lake.	Water Quality, Appendix 6B
KIA 24	Action levels and the response framework will be provided in the 2018 AEMP Annual Report, based on the results of the 2017 AEMP Annual Report as the program moves from pre-construction to construction.	AEMP Action Level Assessment, Section 12.2
KIA 27	In 2018, updates will be made to the AEMP Design Plan with refined Action Levels (using baseline and pre-construction data) and a response framework. Data collected in 2018, the first full year of the Construction Phase, will be compared to these Action Levels, and the ecological relevance of each triggered parameter, if appropriate, will be discussed.	AEMP Action Level Assessment, Section 12.2
KIA 29	In the event that nutrient enrichment triggering a low Action Level is detected in 2018, and is attributed to effluent discharge from the diffuser, a response plan will be prepared during the appropriate time frame following the 2018 Annual Report.	AEMP Action Level Assessment, Section 12.2

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
INAC	INAC recommends that the annual report include a summary and discussion of the relevant AEMP results. Agnico Eagle committed to including a summary of the 2018 AEMP Annual Report findings within the annual report.	Executive Summary
ECCC 6	ECCC recommends that the Proponent identify reference areas with similar substrate to the Near-field exposure area. Agnico Eagle committed to providing the results of the 2018 sediment reconnaissance survey and the adjusted sediment sampling locations in the 2018 AEMP Annual Report.	Sediment Quality, Section 8.2.1 Benthic Invertebrate Community, Appendix 9A and Section 9.2.1
ECCC 7	Magnitude and direction of statistically significant differences between exposure and reference areas will be included in future reports when statistical results are presented.	Water Quality, Section 6.4.2.1.2, Table 6.4-3 and 6.4-4 Sediment Quality, Section 8.4.2.2, Table 8.4-6 Benthic Invertebrate Community, Table 9-5
ECCC 8	Normal Ranges will be recalculated and presented in the 2018 AEMP Annual Report. Inclusion of pre-2017 data from the Near-field exposure area in the calculation of the Normal Ranges will be evaluated and data will be excluded if determined to be different from reference area data.	Water Quality, Section 6.4.3 Sediment Quality, Section 8.4.4 Benthic Invertebrate Community, Section 9.2.4.4
ECCC 11	Further analysis of the water chemistry data for the pre-construction and construction phases will be completed for the 2018 AEMP Annual Report, and differences between areas and between mine phases will be identified, if any, and addressed in the 2018 report.	Water Quality, Section 6.4.5
ECCC 13	The magnitude of the difference in grain-size adjusted metal concentrations in sediment will be clarified in the 2018 AEMP Annual Report.	Sediment Quality, Section 8.4.2.2, Table 8.4-6
ECCC 14	The 2018 AEMP Annual Report will clarify what sediment data are included and excluded from the statistical analysis.	Sediment Quality, Section 8.4.2.2 and Appendix 8F
ECCC 17	ECCC recommends that the Proponent consider multivariate methods to assess the Bray-Curtis Index. NMDS multivariate analysis was used in the 2017 AEMP Annual Report and has been widely used in northern mining programs but following review of the 2018 benthic and supporting data, other methods, where appropriate, could be considered.	Benthic Invertebrate Community, Section 9.2.4.5.4
ECCC 19	Subsampling precision in the benthic invertebrate community samples will be evaluated in the 2018 AEMP Annual Report.	Benthic Invertebrate Community, Section 9.2.3 and Appendix 9B

Table 1.4-1: Concordance Table of EEM Requirements or AEMP Commitments

Item No.	EEM Requirement or AEMP Commitment	2018 EEM/AEMP Combined Report Section No.
ECCC 22	To support wholistic interpretations of fish tissue chemistry, a review of supporting data will be completed in future reports.	Not applicable – fish tissue chemistry was not collected this year
ECCC 24	The results for the plume delineation study will be incorporated into the discussion for the 2018 AEMP Annual Report.	Site Characterization, Section 2.5.3

a) Requirements for the first interpretative report as per the MDMER Schedule 5, Section 12.

b) Commitments made in response to comments made by reviewers on the 2017 AEMP Annual Report. References to the original comment are provided in the first column.

AEMP = Aquatic Effects Monitoring Program; EEM = Environmental Effects Monitoring; MDMER = Metal and Diamond Mining Effluent Regulations; No. = number.

2.0 SITE CHARACTERIZATION

2.1 Environmental Setting

The Mine is located in the Kivalliq Region of Nunavut, near the western shore of Hudson Bay, Canada. Continuous permafrost underlies the ground surface and the terrain is gently rolling with a mean elevation of 65 m above sea level. Drumlins (i.e., glacial till) and eskers (i.e., gravel and sand) are among the dominant land forms within the region. The climate is characterized by long, cold winters and short, cool summers. Total annual precipitation is less than (<) 30 cm and strong winds are prevalent due to the openness of the landscape.

Given that low lying areas are poorly drained, the landscape is characterized by a series of interconnected shallow ponds and lakes. Local watersheds include Meliadine Lake and the Chickenhead and Control sub-watersheds that drain to Meliadine Lake, Meliadine River, and several smaller watersheds. Aquatic habitats support a variety of fish species, including Arctic char (*Salvelinus alpinus*), Arctic grayling (*Thymallus arcticus*), Burbot (*Lota lota*), Cisco (*Coregonus clupeaformis*), Lake trout (*Salvelinus namaycush*), Ninespine stickleback (*Pungitius pungitius*), Round whitefish (*Prosopium cylindraceum*), Slimy Sculpin (*Cottus cognatus*), and Threespine stickleback (*Gasterosteus aculeatus*). Dominant benthic invertebrates previously documented in Meliadine Lake include insects (mostly midges [Chironomidae]), mollusks (fingernail clams [Pisidiidae]), aquatic worms (Oligochaeta), and amphipods (shrimp-like crustaceans) (Golder 2013b).

The region supports some of Canada's largest caribou (*Rangifer tarandus groenlandicus*) herds during the calving season and summer, including the Qamanirjuaq Caribou Herd, which is an important food source for the Inuit. Carnivores such as gray wolf (*Canis lupis*) and polar bear (*Ursus maritimus*) are also found in the region, as are nesting and breeding migratory birds. Protected areas of the Kivalliq region include Arvia'juaq and Qikiqtaarjuk National Historic Site of Canada, East Bay Migratory Bird Sanctuary, Fall Caribou Crossing National Historic Site of Canada, Harry Gibbons Migratory Bird Sanctuary, Iqalugaarjuup Nunanga Territorial Park, Inuujarvik Territorial Park, McConnell River Migratory Bird Sanctuary, and part of the Thelon Wildlife Sanctuary.

Over 80% of the human population in the Kivalliq Region is Inuit. The area is sparsely populated, and the local economy is dependent on subsistence hunting, trapping, and fishing. Other activities in the area include mineral exploration, mining, construction, tourism, and government services.

2.1.1 Meliadine Lake

Meliadine Lake has a water surface area of approximately 107 km^2, a maximum length of 31 km. The lake features a highly convoluted shoreline and has 243 islands (Golder 2014a). Unlike most lakes, Meliadine Lake has two outflows that drain into Hudson Bay through two separate river systems (Figure 1.1-1). It has a drainage area of 560 km^2 upstream of its two outflows. The majority of drainage occurs via the Meliadine River, which originates at the southwest end of the lake. The Meliadine River flows for a total stream distance of 39 km through a series of waterbodies, until it reaches Little Meliadine Lake and then continues to flow to Hudson Bay. The second, smaller outflow from the west basin of Meliadine Lake drains into Peter Lake, which discharges into Hudson Bay through the Diana River system (a stream distance of 70 km). At its mouth, the Diana River has a drainage area of 1,460 km^2.

Meliadine Lake has a long shoreline perimeter of 465 km (Golder 2014a). Meliadine Lake consists of three sub-basins: east, south, and west (Figure 2.5-1). The east basin of Meliadine Lake is 2,212 ha and contributes approximately 21% to the entire area of the lake. It is separated from the rest of the lake by a shallow and narrow area (up to 2.3 m deep, 100 to 300 m wide, and 800 m long) that features numerous rocky islands and reefs.

This constriction may result in isolation of the east basin from the rest of the lake during winter, which may limit movement of fish (Golder 2014a). The west basin, which contains proposed Reference Areas 1 and 2, represents approximately 68% of the lake area and connects the east and south basins. The south basin of Meliadine Lake is 1,135 ha and contributes approximately 11% to the entire lake area (Golder 2014a). The southeast end of the south basin is generally shallow (less than 4 m deep), and the northwest sections feature more extensive areas of water deeper than 8 m.

More than one third of Meliadine Lake volume is contributed by lake areas that are less than 2 m in depth, which indicates a considerable reduction in lake volume and overwintering potential during winter. Owing to the long shoreline perimeter and the shallow nature of the basins, the littoral zones (i.e., areas less than 6 m in depth) contribute approximately 66% and 72% of the east and south basins, respectively (Golder 2014a).

Substrate in Meliadine Lake is characterized by coarse materials, consisting of a boulder/cobble mix along the shallow areas close to shore. Transition areas, consisting of fine organic materials interspersed among cobble are common throughout most of the lake. Substrates within the deep sections of the lake are composed primarily of fine particulate organic material and silt (Golder 2014a).

2.1.2 Peninsula Lakes

Several small watersheds drain to Meliadine Lake from the peninsula between the south and east basins of Meliadine Lake. These peninsula watersheds comprise an extensive network of lakes, ponds, and interconnecting streams. The lakes within the peninsula are generally small (<90 ha in area) and shallow (between 2 and 5 m in maximum depth). They do not freeze to the bottom. They are connected to each other (and to Meliadine Lake) through short stream sections; however, they can often be isolated by limited flow during the summer/fall and frozen stream conditions during the winter.

Three peninsula lakes were selected for water quality monitoring as part of the AEMP: Lake A8, Lake B7, and Lake D7. These are headwater lakes in three different peninsula watersheds and are located close to the Mine footprint. Two of the lakes (Lakes B7 and D7) were previously fished by the Inuit during the winter (pers. comm. Wesley from Rankin Inlet Hunters and Trappers Organization). Some morphological characteristics of these peninsula lakes are provided in Table 2.1-1.

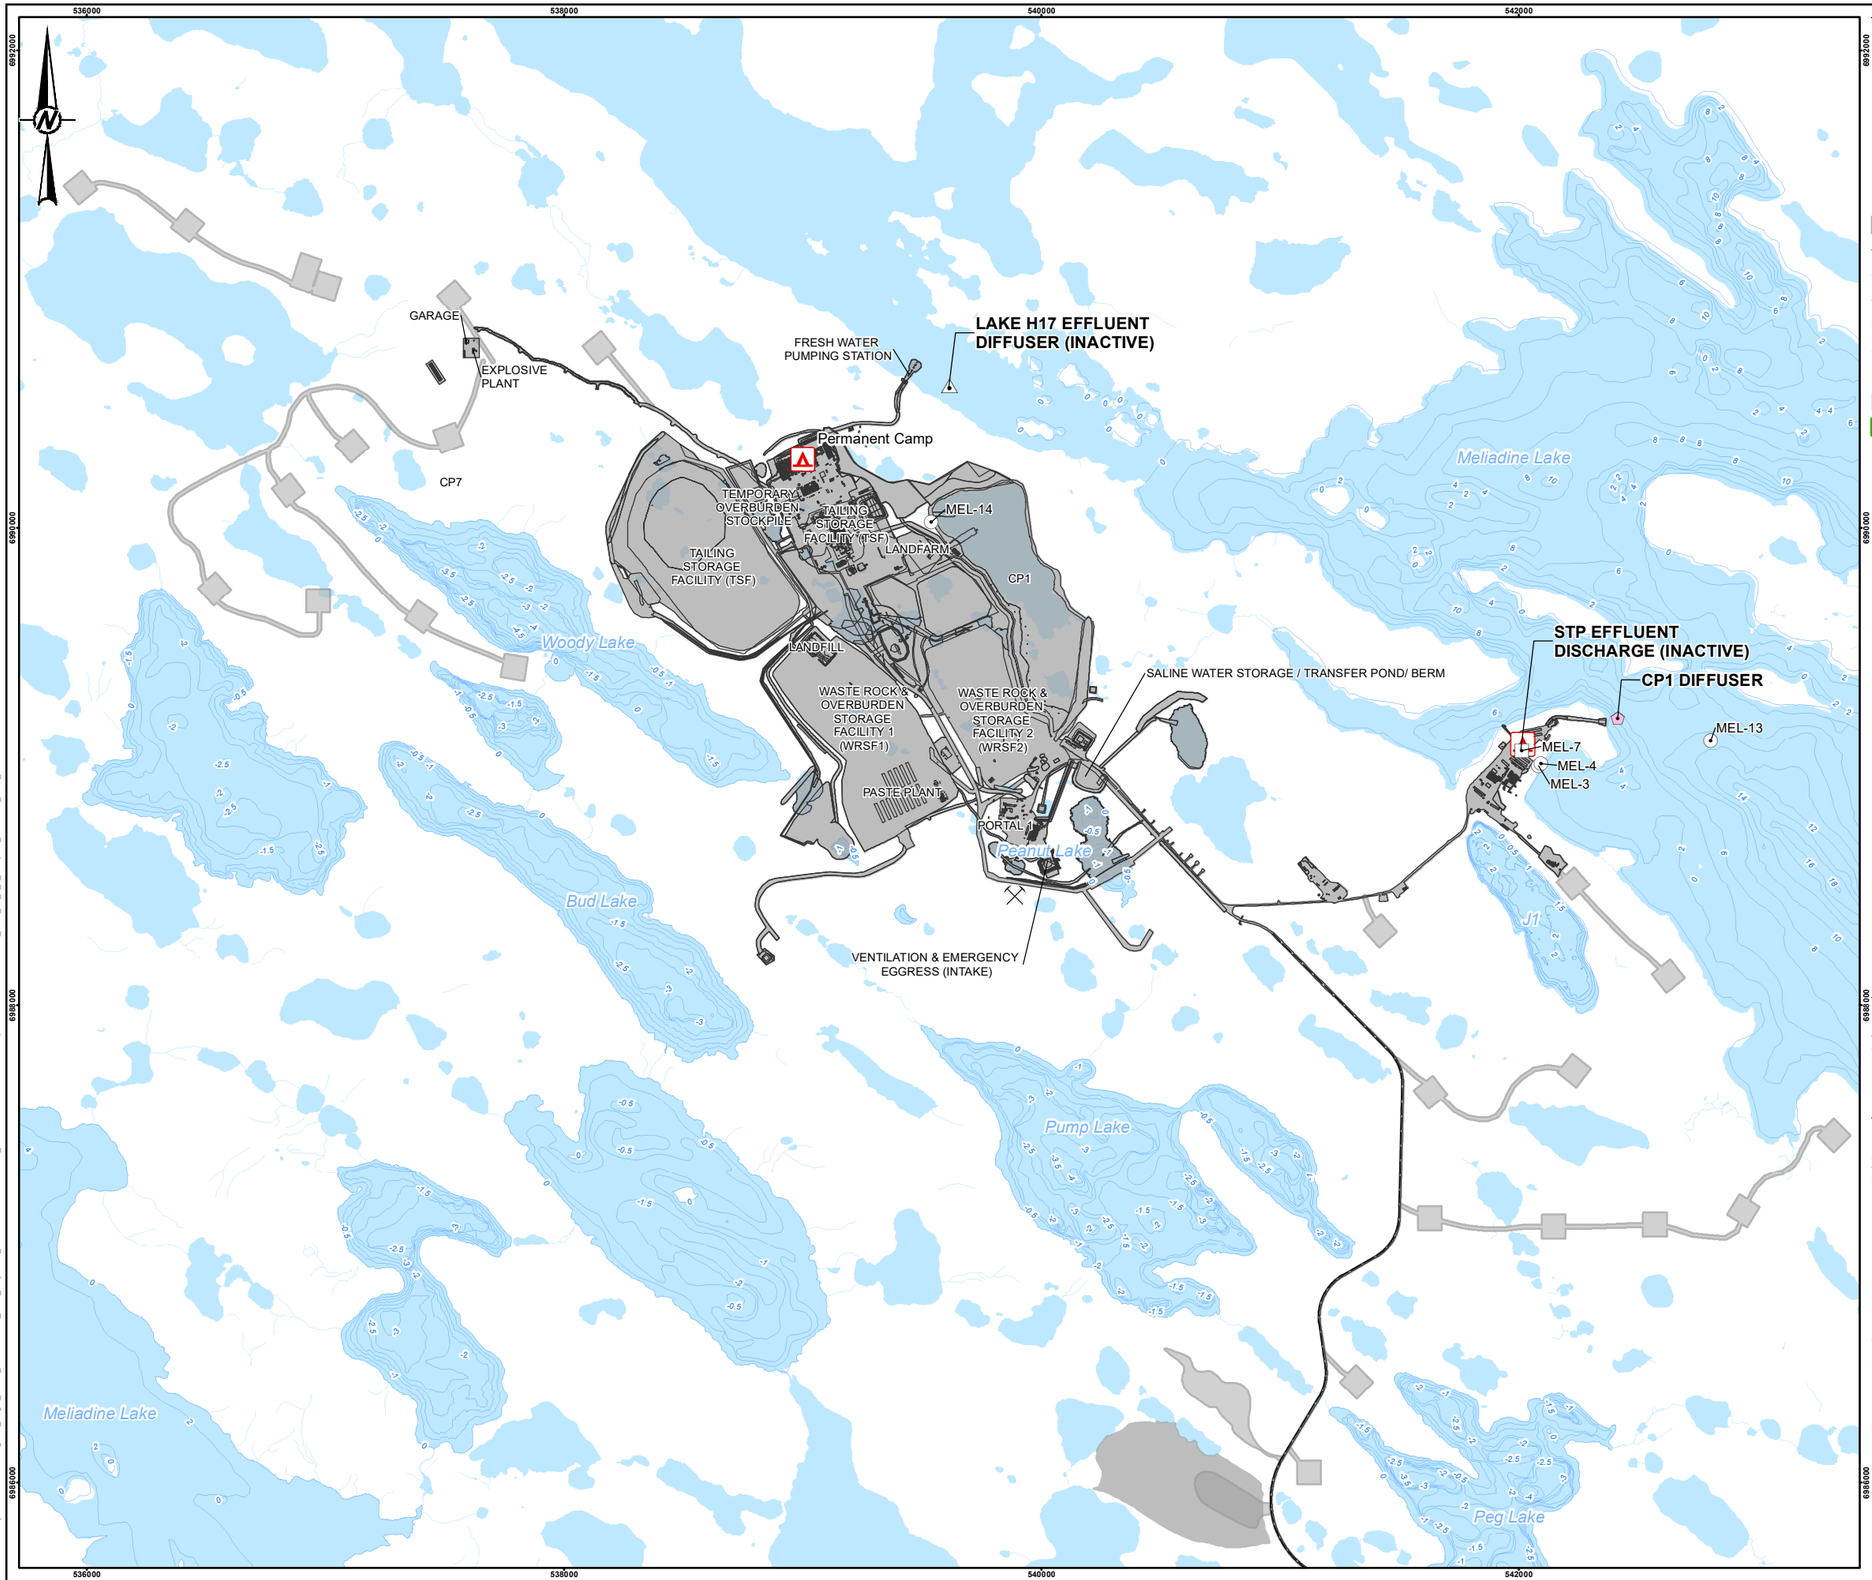
Table 2.1-1: Morphological Characteristics of AEMP Peninsula Lakes

Lake	Surface Area (ha)	Volume ($m^3 \times 10^3$)	Depth (m)		Total Shoreline Length (km)
			Mean	Maximum	
A8	89.7	1,419.3	1.6	4.2	7.5
B7	58.1	852.5	1.5	5.1	5.5[(a)]
D7	72.5	1,183.4	2.8	5.2	5.2

Source: Golder. 2009. Aquatic Baseline Synthesis Report.

(a) Includes shoreline length around two islands.

2.2 Mine Description and Summary of Activities from 2018



The Mine plan proposes open pit and underground mining methods for the development of the Tiriganiaq gold deposit, with two open pits (Tiriganiaq Pit 1 and Tiriganiaq Pit 2) and one underground mine (Figure 2.2-1). The Mine is expected to produce approximately 14.9 million tonnes (Mt) of ore. The produced ore will be milled over approximately eight years of Mine life at a rate of 3,000 tonnes per day (tpd) in Year 1 to Year 3 and 5,000 tpd in Year 4 to Year 8. Of the total 14.9 Mt of tailings produced, about 10.9 Mt of tailings will be placed in the tailings storage facility as dry stack tailings, while the remaining 4.0 Mt will be backfilled to the underground mine as cemented paste backfill. Approximately 31.4 Mt of waste rock will be mined from the open pits and underground mine operations. Approximately 7.1 Mt of overburden will be produced.

The four development phases of Tiriganiaq gold deposit include three and a half years of construction (Q4 Year-5 to Q2 Year-1), eight and a half years mine operation (Q2 Year 1 to Year 8), three years closure (Year 9 to Year 11), and post-closure (Year 11 forward; Agnico Eagle 2015; Table 2.2-1). Pre-construction activities were completed at the Mine between January 2015 and June 2017, and construction activities were initiated in July 2017 (Table 2.2-1).

Table 2.2-1: Timelines of Mine Phases

Mine Phase	Planned Timelines	Total Time (years)
Pre-construction	Beginning of Q1 2015 to end of Q3 2017	2.5
Construction	Beginning of Q3 2017 to end of Q4 2020	3.5
Operation	Q2 2019 to Q4 2027	8.5
Closure	Q4 2027 to Q4 2030	3.0
Post-Closure	Q4 2030 - Forward	-

Notes: Q = calendar quarter where Q1 = January, February, March; Q2 = April, May, June; Q3 = July, August, September; and Q4 = October, November, December.

Water management activities that occurred in 2018 included transporting treated sewage effluent to CP1 (starting in November 2017), and initiation of mine effluent discharge through the CP1 diffuser to Meliadine Lake in June 2018. Water quality monitoring associated with the final discharge point MEL-14 and the receiving environment station above the CP1 diffuser (i.e., MEL-13) was conducted during the discharge period (Figure 2.2-1). Water from landfarm A was treated with an oil/water separator; oil was disposed of as hazardous material and water was sent to CP1. While landfarm B contains material, no additional material was added in 2018. Water from landfarm B was also treated with an oil/water separator; oil was disposed of as hazardous material and water was sent to P1. The design report for the freshwater intake was submitted on June 8, 2018 and approved on July 5, 2018 (Tetra Tech 2017). In-water works associated with the freshwater intake causeway did not occur during the open water season of 2018; all work for the water intake occurred on ice.

Water quality monitoring outside of the EEM program and the AEMP occurs at Meliadine Lake as part of the requirements under MDMER and the WL. The MDMER requires monthly effluent discharge volume and loadings, weekly effluent monitoring of deleterious substances and pH, monthly acute lethality testing of effluent, expanded effluent characterization concurrently with the biannual sublethal toxicity testing, and quarterly surface water quality monitoring in an exposure and reference area. The data are provided in an annual MDMER report to ECCC by 31 March of each year. The monitoring stations are described in Table 2.2-1. The WL requires water quality monitoring at several locations related to dewatering discharge, freshwater intake, water treatment plant discharge, seepage, and receiving environment monitoring (Table 2.2-1). The data are provided in an annual report to the NWB by 31 March of each year. Note that this EEM/AEMP report focuses on monitoring conducted at the EEM and AEMP exposure and reference areas; see Section 2.5 for a description of these areas.

Table 2.2-2: Overview of 2018 Monitoring Stations at Meliadine Gold Mine

Monitoring Station	Description	Reporting Requirement
MEL-14	Effluent from the water treatment plant (post-treatment = water prior to discharge to the receiving environment)	MDMER and WL
MEL-13	Surface water quality monitoring location in the exposure area in Meliadine Lake	MDMER and WL
MEL-03-01	Surface water quality monitoring location in the reference area	MDMER
MEL-1	Raw water supply intake at Meliadine Lake for the exploration camp (only intake volume is monitored)	WL
MEL-2	Raw water supply intake at Pump, A8, or other Lakes (only intake volume is monitored)	WL
MEL-7	Treated sewage effluent from exploration camp	WL
MEL-11	Water intake from Meliadine Lake	WL
MEL-12	Influent from water treatment plant (pre-treatment = water coming from CP1)	WL
MEL-15	Lake E2 located west of the Mine site	WL
MEL-16	Lake G2 located northwest of the Mine site	WL
MEL-17	Lake H1 located east of the Mine site	WL
MEL-18	Lake B5 located southwest of the Mine site	WL
MEL-19	CP2, which is a pond that collects natural catchment drainage from the outer berm slopes of the landfarm and industrial pad. No sample collected in 2018 because no water accumulated in this pond in 2018.	WL
MEL-20	Lake B28, which will become CP3 once construction is completed. CP-3 will collect drainage from dry stacked tailings located west of the Mine site.	WL

Table 2.2-2: Overview of 2018 Monitoring Stations at Meliadine Gold Mine

Monitoring Station	Description	Reporting Requirement
MEL-21	Lake B8, which will become CP4 once construction is completed. CP-4 will collect drainage from the WRSF1 located west of the Mine site.	WL
MEL-22	CP5, which was previously Lake A54 and is now a collection pond consisting of drainage from WRSF1 and WRSF2. Located south of the Mine site.	WL
MEL-23	Lake H19, which will become CP6 once construction is completed. CP-4 will collect drainage from the WRSF3 located east of the Mine site.	WL
MEL-24	Seepage from the landfill between the landfill and Pond H3, as well as drainage from other nearby areas.	WL
MEL-25	Secondary containment area at the Itivia Site Fuel Storage and Containment Facility.	WL

WRSF = Waste Rock Storage Facility.

2.3 Interactions with the Aquatic Environment

The Project will interact with the aquatic environment throughout all phases of Mine development through the following pathways:

- the release of treated effluent;
- the release of air emissions (i.e., acidifying emissions, dust, and associated metals);
- the alteration of natural watersheds;
- potential accidental seepage and spills; and
- Influence from underground workings.

Project components specific to the Peninsula Lakes that may affect the aquatic environment include the altering watersheds through dewatering operations, diverting natural drainage paths, constructing new drainage channels, and changing the water balance.

2.4 Treated Mine Effluent

Mine effluent discharge to the receiving environment of Meliadine Lake is permitted under Type A Water Licence 2AM-MEL1631 (NWB 2016). Mine effluent consists of treated effluent from CP1. CP1 receives water from surface runoff from the project footprint and from another surface water runoff collection pond, CP5. Water from CP5 is highly saline and is treated to reduce dissolved solids by reverse osmosis (RO) membrane treatment prior to transferring to CP1. Prior to discharge into Meliadine Lake, water from CP1 is treated at the Effluent Water Treatment Plant (EWTP) with ActiFlow treatment. Treated effluent is discharged to Meliadine Lake through a permanent diffuser (CP1 diffuser; Figure 2.2-1) located in the AEMP Near-field area. MEL-14 is the final point of control for the treated effluent and is the effluent compliance point (Figure 2.2-1). MEL-13 is the receiving environment monitoring station that is located directly above the diffuser (Figure 2.2-1).

2.4.1 Discharge Volume

Effluent was discharged daily from the EWTP into Meliadine Lake from June to September 2018 (Table 2.4-1). A total volume of 642,521 m^3 was discharged into Meliadine Lake through MEL-14 during the 75-day discharge period (June 21 to September 3) (Appendix 2A).

Table 2.4-1: Monthly Discharge Volume into Meliadine Lake from MEL-14 in 2018

Month	Total Volume (m^3)
June	134,272
July	352,551
August	153,066
September	2,632
Total	**642,521**

2.4.2 Effluent Quality

Samples for effluent chemistry and toxicity were collected at the last point of control (i.e., MEL-14). Water quality was also collected in the receiving environment directly above the CP1 diffuser (i.e., at MEL-13 within the mixing zone). Additional details on monitoring at MEL-14 and MEL-13 are described in the Water Management Plan (Agnico Eagle 2016).

2.4.2.1 Chemistry

Discharge limits must be achieved to maintain compliance with the Type A Water Licence (2AM-MEL1631; NWB 2016) and the MDMER (Government of Canada 2018).

As per Part F, Item 3 of the Water Licence (NWB 2016), the discharge of effluent from the final discharge point at monitoring program station MEL-14 shall be directed to Meliadine Lake through the Meliadine Lake outfall diffuser (i.e., CP1 diffuser) and shall not exceed the effluent quality limits as presented in Table 2.4-2. Discharge chemistry is to be monitored prior to discharge and weekly during discharge and discharge volume is monitored weekly (Schedule I, Table 2 of the Water Licence; NWB 2016).

Table 2.4-2: Effluent Quality Limits for the Discharge of Effluent from MEL-14, as per the Water Licence (NWB 2016)

Parameter	Unit	Maximum Average Concentration	Maximum Concentration of Any Grab Sample
pH	-	6.0 to 9.5[(a)]	6.0 to 9.5[(a)]
Total Dissolved Solids (measured)	mg/L	1,400	1,400
Total Suspended Solids	mg/L	15[(a)]	30[(a)]
Total Phosphorus	mg/L	2.0	4.0
Total Aluminum	mg/L	2	3
Total Arsenic	mg/L	0.3	0.6
Total Cyanide	mg/L	0.5	1.0
Total Copper	mg/L	0.2	0.4
Total Ammonium	mg/L	14	18
Total Nickel	mg/L	0.5[(a)]	1.0[(a)]

Table 2.4-2: Effluent Quality Limits for the Discharge of Effluent from MEL-14, as per the Water Licence (NWB 2016)

Parameter	Unit	Maximum Average Concentration	Maximum Concentration of Any Grab Sample
Total Lead	mg/L	0.2[(a)]	0.4
Total Zinc	mg/L	0.4	0.8
Total Petroleum Hydrocarbons	mg/L	5	5

a) Adopted from Metal and Diamond Mining Effluent Regulations (Government of Canada 2018).

As per the MDMER (Government of Canada 2018), the Mine is permitted to discharge an effluent containing any deleterious substance if the concentration of deleterious substance in the effluent does not exceed the maximum authorized concentrations that are set out in columns 2, 3 and 4 (Table 2.4-3). Effluent chemistry is monitored weekly for these deleterious substances.

Table 2.4-3: Authorized Limits of Deleterious Substances as per the MDMER Schedule 4 (Government of Canada 2018)

Item	Column 1	Column 2	Column 3	Column 4
	Deleterious Substance	Maximum Authorized Monthly Mean Concentration	Maximum Authorized Concentration in a Composite Sample	Maximum Authorized Concentration in a Grab Sample
1	Arsenic	0.50 mg/L	0.75 mg/L	1.00 mg/L
2	Copper	0.30 mg/L	0.45 mg/L	0.60 mg/L
3	Cyanide	1.00 mg/L	1.50 mg/L	2.00 mg/L
4	Lead	0.20 mg/L	0.30 mg/L	0.40 mg/L
5	Nickel	0.50 mg/L	0.75 mg/L	1.00 mg/L
6	Zinc	0.50 mg/L	0.75 mg/L	1.00 mg/L
7	TSS	15.00 mg/L	22.50 mg/L	30.0 mg/L
8	Radium 226	0.37 Bq/L	0.74 Bq/L	1.11 Bq/L

TSS = total suspended solids; mg/L = milligrams per litre; Bq/L = becquerel per litre.

In addition to the above effluent monitoring, mines are required under the MDMER to analyze additional parameters in effluent as part of the effluent characterization (as per Schedule 5, Section 4). This effluent characterization is required quarterly, and samples must be collected at least one month apart.

Effluent quality for samples collected from MEL-14 in 2018 are presented in Table 2.4-4 and Appendix 2B. Effluent chemistry met the MDMER effluent limits (Table 2.4-4). Total dissolved solids (TDS) concentrations exceeded the Water Licence effluent limits in one sample collected in July 2018 (1,430 mg/L) and total aluminum concentration exceeded the effluent limit in one sample collected in August (4.39 mg/L) (Appendix 2B). While TDS concentrations were generally elevated in the effluent samples throughout the sampling period, the high total aluminum value in the 23 July sample was anomalous in comparison to results in other samples. Total aluminum concentrations in effluent were generally variable, with a large range of measured values (i.e., 5.0 to 1,320 mg/L; Appendix 2B). Concentration of TSS in the 23 July was slightly elevated at 21 mg/L, but not enough to explain the much higher total aluminum concentration (Appendix 2B). Dissolved aluminum concentration in this sample (i.e., 0.099 mg/L) was within the range of other values (i.e., 0.0043 to 0.22 mg/L; Appendix 2B).
Elevated aluminum concentration was also observed in the corresponding receiving environment sample,

despite relatively low TSS of 1.0 mg/L (see Appendix 2C). Overall, the total aluminum exceedance appears anomalous and should be interpreted with caution.

Water quality for samples collected from MEL-13 (i.e., receiving water directly above the diffuser) are presented in Table 2.4-5 and Appendix 2C. This station provides additional information about water quality within the mixing zone. Total aluminum, total copper, and total iron concentrations exceeded the Canadian Water Quality Guidelines for the Protection of Aquatic Life (CWQG-PAL; CCME 1999) in one sample collected in July 2018 (Appendix 2C). Aesthetic objectives for drinking water quality were exceeded for water temperature, iron, and manganese in this sample. All other concentrations were less than the CWQG-PAL, CDWQG (Health Canada 2017), and Site-Specific Water Quality Objectives (SSWQO; Golder 2013b).

mg/L = milligrams per litre; µS/cm = microSiemens per centimetre; mg-N/L = milligrams nitrogen per litre; mg-P/L = milligrams phosphorus per litre; Bq/L = becquerels per litre; + = plus; °C = degrees Celsius; NTU = nephelometric turbidity unit; $CaCO_3$ = calcium carbonate; SiO_2 = silicon dioxide; BTEX = benzene, toluene, ethylbenzene, and xylene; Min = minimum; Max = maximum; SD = standard deviation; nd = not detected; <= less than ; % = percent; MDMER = Metal and Diamond Mining Effluent Regulations; - = parameter below water quality guideline or objective, or no guideline/objective or no data.

2.4.2.2 Acute and Sublethal Toxicity

As per Schedule I Table 2 of the Water Licence (NWB 2016), acute lethality testing of mine effluent is required prior to discharge and monthly thereafter. Effluent must not be acutely lethal to Rainbow Trout (Part F, Section 4). Monthly acute lethality testing is also required under the MDMER, with the same prohibition of discharge of acutely lethal effluent.

Sublethal toxicity testing is required as part of EEM. Tests are conducted twice per year on aliquots of the same effluent sample submitted for effluent characterization.

Methods

Acute lethality testing was performed using the following test protocols:

- Environment Canada (2000a): Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Rainbow Trout (EPS 1/RM/13)
- Environment Canada (2000b): Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to *Daphnia magna* (EPS 1/RM/14)

An acutely lethal effluent is defined as an effluent at 100% concentration that kills more than 50% of the rainbow trout exposed during a 96-hour period (Government of Canada 2018). Testing with *Daphnia* was performed to provide additional information of acute toxicity. The effluent samples were submitted to Eurofins Environmental Testing, Saint-Augustin-de-Desmaures, Quebec, for acute lethality testing.

Sublethal toxicity testing was performed using the following test protocols:

- Environment Canada (2011): Biological Test Method: Test of Larval Growth and Survival Using Fathead Minnows (EPS 1/RM/22)
- Environment Canada (2007a): Biological Test Method: Test of Reproduction and Survival Using the Cladoceran *Ceriodaphnia dubia* (EPS 1/RM/21)
- Environment Canada (2007b): Biological Test Method: Test for Measuring the Inhibition of Growth Using the Freshwater Macrophyte, *Lemna minor* (EPS 1/RM/37)
- Environment Canada (2007c): Biological Test Method: Growth Inhibition Test Using a Freshwater Alga (EPS 1/RM25)

The effluent samples were submitted to AquaTox Testing & Consulting Inc., Puslinch, Ontario, for sublethal toxicity testing.

Results

Monthly mine effluent samples collected from MEL-14 from June to September 2018 were not acutely toxic to Rainbow Trout or *Daphnia magna* (Table 2.4-6; Appendix 2D).

Three mine effluent samples collected from MEL-14 in August and September 2018 did not adversely affect Fathead Minnow (*Pimephales promelas*) survival and growth, or green algae (*Pseudokirchneriella subcapitata*) growth. Stimulation of growth was observed in the green algae tests. Sublethal effects were observed on growth of common duckweed (*Lemna minor*) in two of the three samples, and on reproduction of the water flea (*Ceriodaphnia dubia*) in one sample (Table 2.4-7). Sublethal toxicity test reports are provided in Appendix 2E.

Table 2.4-6: Summary of Acute Lethality Data for MEL-14, 2018

Date	Acute Toxicity to Rainbow Trout		Acute Toxicity to *Daphnia magna*	
	% Mortality in 100% Effluent	LC50 (%v/v)	% Mortality in 100% Effluent	LC50 (%v/v)
24-Jun-2018	10	>100	0	>100
1-Jul-2018	0	>100	0	>100
5-Aug-2018	0	>100	0	>100
3-Sep-2018	0	>100	0	>100

LC50 = median lethal concentration; %v/v = percent volume by volume; > = greater than.

Table 2.4-7: Summary of Sublethal Toxicity Data for MEL-14, 2018

Species	Endpoint	Test Results (%v/v)		
		07-Aug-2018	13-Aug-2018	03-Sep-2019
Pimephales promelas	LC50	>100	>100	>100
	IC25 (Growth)	>100	>100	>100
Ceriodaphnia dubia	LC50	>100	-[(a)]	>100
	IC25 (Reproduction)	>100	-[(a)]	90.1 (23.3 to 96.3)
Lemna minor	IC25 (Weight)	>97.0	42.0 (26.5 to 63.2)	>97
	IC25 (Frond Yield)	72.3 (36.4 to 86.5)	38.2 (26.6 to 52.1)	>97
Pseudokirchneriella subcapitata	IC25 (Growth)	>90.91	>90.91	>90.91

Note: The 95% confidence limits, if available, are presented in parentheses. Due to the addition of nutrient spikes, the maximum effluent concentration that can be tested using *Lemna minor* and *Pseudokirchneriella subcapitata* is 97%v/v and 90.91%v/v, respectively.

(a) Test failed laboratory control validity criteria.

LC50 = median lethal concentration; IC25 = inhibition concentration at 25%; %v/v = percent volume by volume; > = greater than.

2.4.2.3 Loadings

As per Part 2, Division 2, Section 20 of the MDMER (Government of Canada 2018), the Mine shall record the loading of deleterious substances (in kg or megabecquerel [MBq]) that are contained in the effluent deposited from each final discharge point (i.e., MEL-14) for each month during which there was a deposit and during which a sample is collected. Monthly loadings are calculated using Equation 1:

$$ML = C \times V / 1{,}000 \quad \text{(Equation 1)}$$

Where ML is the loading for a month in kg, C is the monthly mean concentration of the deleterious substances in mg/L, and V is the total monthly volume of effluent deposited from each final discharge point (i.e., MEL-14) in m^3. The monthly loadings of effluent quality parameters are shown in Table 2.4-8. Loadings of each effluent quality parameter discharged from MEL-14 in July were generally higher than those reported in August and September due to a higher effluent volume (352,551 m^3) released into Meliadine Lake. Daily discharge volumes and concentrations of effluent quality parameters are presented in Appendices 2A and 2B, respectively.

Table 2.4-8: Monthly Loadings of Effluent Quality Parameters Discharged from MEL-14, 2018

2.4.3 Delineation of the Mine Effluent Mixing Zone

A plume delineation study was conducted in July and August 2018. This report section provides a summary of the results. Details of the sampling design are available in Golder (2018c). The plume delineation study was based on previous experience at mines in Northern Canada (Golder 2013a, 2015). Coordinates of the plume delineation study sampling stations are shown in Table 2.4-9.

2.4.3.1 Background Information

Turbulent mixing caused by the diffusers results in an initial effluent plume adjacent to the diffusers. The term “plume” in this section refers to the mixture of treated effluent and lake water that is chemically distinguishable from the surrounding ambient lake water.

A submerged diffuser was installed in Meliadine Lake in August 2017 to disperse the water discharged from CP1. The diffuser is 30 m long, 400 mm diameter, nearly north-south oriented, and connected to the pipelines through a T-connection. Ten 51 mm ports are evenly spaced at every 3 m along the diffuser (Tetra Tech 2017). The as-built diffuser differed from the project design (see Tetra Tech 2017) in terms of its horizontal position and depth of diffuser system at T-connection (42 m horizontal shift and a 3.2 m shallower depth). Therefore, the performance of the diffuser system was reassessed by Tetra Tech in 2018. Despite the deviations from the original design, the predicted minimum dilution of 23:1 was achieved at the edge of the mixing zone, and water quality criteria were met (Tetra Tech 2018).

Based on previous experience in low conductivity subarctic lakes, conductivity was considered an appropriate tracer to delineate the effluent plume in Meliadine Lake, because effluent conductivity (i.e., specific conductivity, temperature-corrected to 25°C) is higher than the conductivity of natural lake water.

CP1 receives water from surface runoff from the project footprint and from another surface water runoff collection pond, CP5. Water from CP5 is highly saline and was treated for TDS by RO membrane treatment prior to transferring to CP1. Specific conductivity in CP1 ranged from 1,100 to 2,500 µS/cm in 2017 and 2018 (Appendix 2F) and in EWTP (MEL-14) results ranged from 1,600 to 2,100 µS/cm (Appendix 2B).

2.4.3.2 Methods

The sampling design selected for the plume delineation in Meliadine Lake is a modified radial grid design that allows measurement of plume dispersion in all directions. According to the MVLWB/GNWT Guidelines for Effluent Mixing Zones (GNWT 2017), the regulated mixing zone is defined as an area where concentrations of some substances may not comply with Site-Specific Water Quality Objectives for the receiving environment. For lakes in the Mackenzie Valley, regulated mixing zones should have a maximum of 100 m radius from the discharge point (GNWT 2017). As per the MDMER (Government of Canada 2018) a description of the manner in which the effluent mixes within the exposure area at 100 m and 250 m from each final discharge point is required for site characterization. Taking this information as starting points, a modified radial grid containing 16 sampling stations was designed (Figure 2.4-1); from these, two stations were sampled in 19 and 23 July 2018 by Golder staff as per the July AEMP field work and fourteen were sampled on 10 August 2018 by Agnico Eagle's staff. Coordinates and dates of all sampling stations visited are given in Table 2.4-9. Although provided in Appendix 2G, the July data were not incorporated in this report because differences in pH (average pH of 7.6 and 8.5) between the July and August data were observed, possibly as a result of different environmental conditions during collection time. The July data were not considered to be reasonably similar enough to the August data to allow inclusion in the final dataset for the plume delineation.

As described by Golder (2018a), the plume delineation was based on vertical profiles of specific conductivity in the Near-field area of Meliadine Lake. Vertical profiles of the lake water column were measured using water quality meters (Eureka Manta II) equipped with a 20 m long cable. The water quality meters were calibrated before going out in the field, and the water quality probe was placed in lake water for at least one minute to allow readings to stabilize. The results obtained during the field work were stable and in the expected range of results.

At each sampling station, profile measurements were taken from surface (i.e., 0.3 m) and at 1-m intervals, starting from 1 m below surface to 1 m above the bottom. Temperature, specific conductivity, dissolved oxygen (DO) concentration, oxygen saturation, and pH were recorded on field data sheets and later transcribed to an Excel spreadsheet by a Golder or Agnico Eagle staff.

Data were plotted using R v. 3.4.2 environment (R Core Team 2018). All data obtained are presented as vertical profile plots, but because of the high number of sampling stations (fourteen), they were grouped based on their distance to the diffuser (50, 100, 175 and 250 m). The locations of these stations are provided in Figure 2.4-1. This approach aimed to simplify the legends and improve readability while retaining the information on distance. Water quality results obtained under the AEMP were used for comparisons with pre-discharge conditions.

The dilution factor provides a result of the mixing characteristics of the discharge; a higher value typically indicates a larger degree of dilution of the discharge in the lake water. Following a conservative approach, the dilution factors were calculated according to the Equation 2.

$$DF = \frac{[C_{eff}]-[C_{amb}]}{[MC_{dif}]-[C_{amb}]} \quad \text{(Equation 2)}$$

Where DF is the dilution factor, $[C_{eff}]$ is the average specific conductivity in the treated effluent (MEL-14) in August 2018, $[MC_{dif}]$ is the maximum specific conductivity at a given plume delineation sampling station, and $[C_{amb}]$ is the average specific conductivity in the Near-field area characterizing pre-discharge conditions during the open water season.

The most recent results for specific conductivity in the treated effluent (MEL-14) were collected on 5 August and 13 August (1,900 and 2,100 µS/cm respectively; Appendix 2B). As the stations for plume delineation measurements were visited on 10 August, the effluent chemistry for these two dates were averaged for use in the dilution factor calculations. The maximum specific conductivity of each sampling location was used to yield the minimum dilution factor possible.

Water quality data collected as part of the AEMP during the open water season were used to characterize pre-discharge conditions in the Near-field area. Discharge from MEL-14 started in June 2018; therefore, data collected before this date can be used to characterize pre-discharge conditions (i.e., July 2015 to July 2017, Golder 2016b; 2017a). Specific conductivity in the Meliadine Lake Near-field area ranged from 49 to 99 µS/cm between 2015 and 2017 (Golder 2016b; 2017a; 2018a). However, average values were slightly higher in 2017 (i.e., 81.3 µS/cm) than in 2015/2016 (i.e., 69.3 µS/cm) (see Figure 2.4-8). The apparent increase in specific conductivity may be due to the discharge of treated sewage effluent into a channel that eventually flows into the bay with the Near-field area.

As stated in the response to comments on the 2017 AEMP Annual Report (Golder 2018a), water quality data collected from July 2017 to present is considered part of the “construction” phase, and data collected prior to July 2017 are considered “pre-construction.” Given the observed slight increase in specific conductivity between the two periods, two different scenarios were calculated based on different estimates of average specific conductivity in the Near-field area:

- Scenario A: near-field average specific conductivity for 2015 to 2016; and
- Scenario B: near-field average specific conductivity for 2017.

2.4.3.3 Results and Discussion

2.4.3.3.1 Physicochemical Profiles

The compiled dataset of vertical profiles measured in July and August 2018 is presented in Table 1 of Appendix 2G. Vertical profile plots are displayed below in Figure 2.4-2 through Figure 2.4-6. Temperature, pH and DO were nearly homogeneous among sampling stations within the same sampling event and within the water column.

Temperature in the August profiles were between 12.5 and 13.2°C, with temperature decreasing with depth (Figure 2.4-2).

In August, DO concentrations were between 9.8 and 10.0 mg/L and oxygen saturation in the water ranged from 92 to 95%. The water column was well oxygenated with small differences between surface and bottom concentrations (Figure 2.4-3 and Figure 2.4-4).

Results for pH obtained in August ranged from 8.4 to 8.6, with very little vertical variation and low variability across sampling stations (Figure 2.4-5).

Specific conductivity results were more variable, ranging from 86 to 106 µS/cm in the profiles taken in August. The variation occurred both horizontally and vertically (Figure 2.4-6). Being the only parameter in which a spatial pattern in variability was observed, corroborates the choice of specific conductivity as the effluent tracer and illustrates the dilution of effluent in the water column at various distances from the diffuser.

2.4.3.3.2 Plume Characterization

In terms of depth, the increases in specific conductivity were observed roughly between 3 and 7 m. Maximum specific conductivity was 106 µS/cm, observed at station 50-03 at a depth of 3 m, followed by station 100-03 at a depth of 4 m. The results for specific conductivity at stations 50-03 and 100-03 at surface and close to the bottom were restricted to a limited range (85 to 90 µS/cm), which is the same specific conductivity range observed for the measurements taken at all depths up to 250 m away from the diffuser. The presence of plume at mid-depth indicates that the receiving water and the effluent have similar densities and/or intense mixing.

Stations where the plume was more noticeable were to the south-west of the diffuser, which indicates a preferential direction of plume advection during the time the field work was completed (Figure 2.4-7). Changes in wind speed and direction are key factors determining the plume dispersion direction.

By analyzing the results of the specific conductivity measurements taken on previous open-water AEMP field campaigns (July 2015 to July 2018, Golder 2016b; 2017a; 2018a), the plume was discernible by the greater variability observed in July 2018. Whereas in previous sampling events, little or no variation among stations was observed, more variation among and within stations was observed in 2018 (Figure 2.4-8). Even in 2017 prior to effluent discharge, water column conductivity was nearly homogeneous. Comparison of these results to the plume delineation results from Figure 2.4-6 clearly shows how effluent discharge affected specific conductivity in the water column of the Near-field area in 2018. Nevertheless, the effect was limited to the stations closer to the diffuser. Evidence of the plume was noticeable at most sampling stations located 100 m away from the diffuser, while 250 m away from the diffuser the plume was no longer evident.

2.4.3.3.3 Dilution Factors

The diffuser was designed to maximize initial mixing of the effluent discharged to Meliadine Lake. The dilution factor provides an assessment of the mixing characteristics, where larger values are indicative of more efficient mixing. The results for the different scenarios of dilution factor calculations are given below in Table 2.4-10.

Table 2.4-10: Dilution Factors in the Near-Field Exposure Area at Meliadine Lake

Sampling Station	Maximum Specific Conductivity in 2018 (µS/cm)	Dilution Factor – Scenario A	Dilution Factor – Scenario B
50-01	99.8	63	104
50-03	105.5	53	79
100-01	93.4	80	159
100-03	104.0	56	85
100-04	102.6	58	90
100-05	98.9	65	109
100-06	88.5	101	266
100-08	96.6	71	125
175-01	94.3	77	148
175-03	91.2	88	194
250-01	88.2	102	278
250-03	88.6	100	263
250-05	87.8	104	295
250-06	86.9	110	343

DF = dilution factor.

Under Scenario A (average specific conductivity for 2015 and 2016), which is the more conservative approach, a minimum dilution factor of 53 was obtained. This scenario used the average specific conductivity 2,000 µS/cm for effluent in August 2018 and 69.3 µS/cm for lake water conductivity between 2015 and 2016. Larger dilution factors were obtained under Scenario B, which used the average specific conductivity for lake water in the Near-field area as observed in 2017.

As a general rule, the dilution factor tended to increase as distance to the diffuser increased, even though there were a few exceptions (e.g., station 100-03 and 100-04). For the sampling stations 250 m away from the diffuser the minimum dilution factor was 100 while at 100 m from the diffuser the lowest dilution factor was 56 at 100-03 (Scenario A). This result was nearly two times higher than the lowest results obtained at 50 m. The calculated dilution factors suggest efficient mixing of the effluent in the Near-field area within 50 m from the diffuser.

2.4.3.4 Conclusions

Plume delineation was successful in that the effluent plume could be measured and characterized in the Near-field area in Meliadine Lake. Evidence of an effluent plume was observed between 50 and 100 m from the diffusers, with slight preference for south-west orientation. Vertical influence of the effluent mixing was restricted to 3 to 7 m depths. Based on the specific conductivity results, the effluent was rapidly diluted in the surrounding water, with a minimum dilution factor of 53 at 50 m from the diffuser. The results indicate that maximum effluent concentration observed at 250 m away from the diffuser was 1%, and less than 2% at 100 m.

2.5 Description of the Exposure and Reference Areas

The exposure area is defined as “all fish habitat and waters frequented by fish that are exposed to effluent,” and the reference area is defined as “water frequented by fish that is not exposed to effluent and that has fish habitat that, as far as practical, is most similar to that of the exposure area (Schedule 5, Section 1; Government of Canada 2018).”

The exposure and reference areas are both located within Meliadine Lake. Within-lake reference areas were selected for the following reasons:

- The quantity of effluent to be released is small (maximum annual water volume of 729,000 cubic metres during operations; Agnico Eagle 2016) relative to the volume of Meliadine Lake (east and south basins estimated at 98,851,000 cubic metres and 48,429,000 cubic metres, respectively).
- Concentrations at the edge of the mixing zone (100 m from the diffuser) were predicted to be at or less than CWQG-PAL and CDWQG (FEIS, Volume 7; Golder 2014a).
- The effluent discharge point is approximately 20 km from the outlet in the northwest basin (secondary outlet) and 48 km from the outlet in the southwest basin (main outlet).
- The target small-bodied fish species for the Fish Population study is Threespine Stickleback (*Gasterosteus aculeatus*), based on presence and abundance in the areas studied in Meliadine Lake (Golder 2014). This species is not found in any other regional lake studied to date (Golder 2016a), and individual fish home-range sizes in the exposure area do not overlap with the proposed reference areas.
- No alternative nearby reference lakes with a similar large size and fish assemblage, and accessibility that meets health and safety needs, have been identified (Golder 2014a).

Information on the geology, hydrology, and limnology of Meliadine Lake is provided in Section 2.1. Information on water and sediment quality, and characteristics of BIC and fish populations are provided in Section 3.0.

The Near-field area and at least one Reference area are consistent between the Cycle 1 EEM study and the AEMP. An additional Mid-field exposure area and two additional Reference areas are included in the AEMP. Further description of the exposure and reference areas for each program are provided below.

2.5.1 EEM

2.5.1.1 Exposure Area

The TGD recommends that exposure area sampling be carried out in an area closest to the effluent discharge that ideally supports habitat for both BIC and fish populations, and where effects may be found (Environment Canada 2012). The Near-field area for the Cycle 1 EEM study is located in the vicinity of the CP1 diffuser (Figure 2.6-1). As stated on Section 1.2.1, the Near-field area was relocated to match that of the AEMP (i.e., MEL-01). The coordinates for the Near-field area are provided in Table 2.5-1.

2.5.1.2 Reference Area

The TGD recommends that "where feasible, the reference area should be located in the same waterbody as the effluent discharge, upstream of or beyond any influence from the discharge (Environment Canada 2012)."

The reference area for the Cycle 1 EEM study were located within the northeast bay of Meliadine Lake's West basin (Reference Area 1; MEL-03) (Figure 2.6-1). It is located outside the zone of influence of the mine effluent discharge. The coordinates for the Reference Area 1 (MEL-03) are provided in Table 2.5-1.

2.5.2 AEMP

2.5.2.1 Meliadine Lake

The AEMP study area for the Mine was selected based on the spatial extent of effects predicted in the FEIS (Agnico Eagle 2014c), concerns raised through the FEIS process about potential far downstream effects, and requirements under the federal MDMER requirements (Government of Canada 2018). Reviewers of the FEIS were concerned about potential far-field changes in Meliadine Lake and potential changes as far downstream as Peter Lake. To verify the prediction from the FEIS, address concerns about extent of potential changes, and meet EEM requirements, Meliadine Lake will be monitored in the Near-field area (MEL-01), a Mid-field area (MEL-02), and three downstream reference areas (Figure 2.5-1 and Table 2.5-1). Two reference areas will be located near the two lake outlets (Reference Area 4 [MEL-04] and Reference Area 5 [MEL-05]). One reference area is located within the northeast bay of the lake's west basin (Reference Area 1 [MEL-01]). The reasons for selecting reference areas within Meliadine Lake rather than separate reference lakes are provided above.

2.5.2.2 Peninsula Lakes

Monitoring of Peninsula Lakes is intended to assess indirect effects from the Mine, such as alteration of natural watersheds and potential effects from dust deposition. Headwater lakes (Lake A8, Lake B7, Lake D7) in three peninsula watersheds were selected (Table 2.5-1). The selected peninsula lakes include two lakes close to the proposed mine footprint that were previously fished by the Inuit (Lakes B7 and D7) during winter (Golder 2016a).

Table 2.5-1: Exposure and Reference Areas in Meliadine Lake, 2018

Waterbody	Area	Monitoring Program	UTM Coordinates (NAD 83, Zone 15V)		Geographic Coordinates	
			Easting (m)	Northing (m)	Latitude	Longitude
Meliadine Lake	Near-field Exposure (MEL-01)	EEM and AEMP	542657	6989124	92° 9'25.24"W	63° 1'45.14"N
	Mid-field Exposure (MEL-02)	AEMP	537611	6992659	92°15'21.25"W	63° 3'41.38"N

2.6 Additional Considerations – Potential Confounding Factors

Under Schedule 5, Section 12 of the MDMER, the first interpretative report is required to describe "the presence of anthropogenic, natural or other factors that are not related to the effluent under study and that may reasonably be expected to contribute to any observed effect" (Government of Canada 2018). Due to the remote location of the Mine, there are limited anthropogenic influences other than the Mine (e.g., public recreational areas, infrastructure, or industrial developments) that could contribute to effects in the study area beyond those associated with the Mine itself (e.g., dust and associated local aerial deposition). The following sub-sections outline potential Mine-related factors other than mine effluent discharge and dust deposition that may confound the determination of effects of the mine effluent on the receiving environment in Meliadine Lake or the Peninsula Lakes.

2.6.1 Greywater

Under Water Licence 2BB-MEL0709 (NWB 2007), exploration camp greywater was discharged to a wetland, which then discharged into Meliadine Lake from 2007 to 2010. Water chemistry was monitored at station MEL-03 in the wetland (UTM 542083E, 6989004N) and at station MEL-04 in Meliadine Lake (UTM 542092E, 6989012N) (Figure 2.2-1).

Greywater samples collected in July and October 2007 showed elevated total phosphorus concentration (3.1 to 3.2 mg/L), which was attributed to the use of phosphate-containing detergents in the kitchen and dry wash activities (Comaplex 2007). Total phosphorus was not detected (detection limit = 0.02 mg/L) in the MEL-04 samples. Total phosphorus was also elevated in 2008 greywater samples, with concentrations of 4.2 mg/L (June 30) and 2.9 mg/L (August 19) (Comaplex 2008a). Total phosphorus was detected at the detection limit of 0.02 mg/L in the concurrent MEL-04 samples. No additional MEL-03 samples were collected in October 2008; one sample was collected at MEL-04 (total phosphorus was not detected at 0.02 mg/L) (Comaplex 2008b).

Greywater volume was not reported in the 2007 and 2008 annual reports. However, water intake related to camp use was reported for part of October and for November 2007; daily average use was 3.8 m^3 in October and 4.3 m^3 in November (Comaplex 2007). Total volume used for camp use from October 2007 to December 2008 was estimated to be 2,007 m^3 (Comaplex 2008b).

2.6.2 Sewage

Under Water Licence 2BB-MEL0914 (NWB 2009), a BIODISK wastewater treatment system (sewage treatment plant; STP) was approved for use at the exploration camp to treat sewage. The camp was typically open from the beginning of April to the end of November. Prior to this, sewage (i.e., human waste) was bagged and incinerated or transported off site to a suitable disposal facility.

In 2009, the BIODISK system and associated wash car (with flush toilets) was in the process of being commissioned or was put into use. The two BIODISK system in operation could handle 125 workers. Treated sewage discharge was monitored at MEL-07 (in the STP) starting in July 2010. There is no mention of a monitoring station in Meliadine Lake associated with MEL-07 (STP) discharge. At some point, greywater was diverted to the STP for treatment instead of discharging through the wetland. At the end of October 2010, the camp entered care and maintenance with two people remaining on site to maintain the microbes in the BIODISK system over the winter. Prior to this, the camp was presumed to be closed over the winter.

Issues with the STP were observed in 2012, and a consultant was hired to help with recurring fecal coliform exceedances. TP concentration in the MEL-07 final effluent discharge from the BIODISK treatment system was as high as 24.7 mg/L in some samples in May 2012, with TKN as high as 116 mg/L. Effluent discharge volume was not reported, nor was camp use intake volumes. In June 2012, camp use intake was 20.6 m^3, and intake declined to ~10 m^3 in November. A report to the inspector with regards to the STP in November 2013 stated "During the quarter, number of people on site decreased from 78 to 45 persons. The flow at STP decreased from 17 to 10 m^3 at the end of the quarter". From 2015 to 2016, additional ultraviolet treatment was added, and the STP was further upgraded to accommodate an increased number of workers at the exploration camp. In April 2016, camp population was between 115 to 137 people, and was as high as 220 people in October 2017. Over the past few years, TP concentration in the STP effluent was relatively consistent around 11 to 16 mg/L.

Starting in November 2017, exploration camp STP effluent was trucked to the main camp STP for treatment due to recurring issues with fecal coliforms. All treated sewage discharge was diverted to CP1, and therefore further treatment occurred through the wastewater treatment plant prior to discharge through the Meliadine Lake main diffuser (MEL-14). Discharge through the main diffuser into Meliadine Lake did not occur until June 2018.

The estimated annual loadings of nutrients directly or indirectly discharged from MEL-07 from the exploration camp STP indirectly into Meliadine Lake in 2013, 2015, 2016, 2017, and 2018 is shown in Table 2.6-1. Physicochemical characteristics and monthly loadings of sewage discharged from MEL-07 in previous years are provided in Appendix 2B. Total phosphorus loadings were similar in 2013 (52.4 kg) and 2015 (52.9 kg), then doubled in 2016 (100.7 kg) and maintained a similar amount in 2017 (96 kg), before declining in 2018 (22.9 kg). Note that no STP was discharged directly to Meliadine Lake in 2018, so the loadings for 2018 represent those discharged to CP1 and not to Meliadine Lake.

The higher TP loadings in STP discharge aligns with 2016 observations of the BIC showing a nutrient enrichment response pattern that was not present in 2015. Loadings of nitrogen compounds (i.e., nitrate, nitrite, total Kjeldahl nitrogen, and total nitrogen) showed a similar pattern, but nitrogen loadings did not decline in 2018, which could be attributed to mine activities (i.e., increase in use of nitrogenous compounds for blasting, and the resulting nitrogen loading to CP1).

Table 2.6-1: Annual Loadings of Nutrients Directly or Indirectly Discharged from MEL-07 into the Near-field Area, 2013, 2015 to 2018

Year	Project Phase	Type of Effluent Discharge	Nitrate (kg)	Nitrite (kg)	TKN (kg)	TN (kg)	TP (kg)
2013	Baseline	Sewage/grey water	58.7	5.4	86.7	150.8	52.4
2015	Baseline	Sewage/grey water	48.3	10.3	127.6	186.1	52.9
2016	Construction	Sewage/grey water	155.2	14.0	211.2	380.4	100.7
2017	Construction	Sewage/grey water	171.2	17.6	221.0	409.8	96.0
2018[a]	Construction	Mine effluent[b]	3,018	114	1,172	4,304	22.9

a) Discharge occurred from July through to September.

b) Mine effluent under the MDMER (Government of Canada 2018) and Type A Water Licence (NWB 2016).

kg = kilogram; TN = total nitrogen; TP = total phosphorus; TKN = total Kjeldahl nitrogen; MDMER = Metal and Diamond Mining Effluent Regulations.

2.6.3 Spills

One spill and two effluent limit exceedances were reported in 2018.

On February 2, 2018, during an inspection of the exploration camp retention tanks, it was noticed by a member of the Site Services team that water was flowing into Meliadine Lake near the discharge area of the STP. The environment department and site services supervisor were notified immediately, and an inspection was conducted to determine the source of the water. It was discovered that a valve at the base of one of the retention tanks had been left open, resulting in the draining of the contents of all four tanks, which are connected in series. Discharge from the STP had been suspended since November 2017 due to exceedances. Additional information regarding the spill can be found in Appendices 2P and 2Q.

A sample of treated water from MEL-14 (final effluent sampling port prior to discharge to Meliadine Lake) was collected on July 23, 2018. Upon review of the laboratory analysis results, the total aluminum concentration was found to be 4.39 mg/L, which exceeded the permitted discharge limit of 2 mg/L. As per the obligations under the NWB License 2AM-MEL1631, Part F, item 3 pursuant to subsection 12(3) of the Nunavut Waters and Nunavut Surface Rights Tribunal Act, samples were collected for laboratory analysis to assess the total metal concentrations and other water quality parameters during final effluent discharge at MEL-14. The laboratory results were received on August 8, 2018; however, the exceeded criteria for total aluminum concentration was not observed at the initial time of the data review and data input. During the quarterly reporting for MDMER-EEM (RIIS) on October 1, 2018, the exceedance was observed and reported immediately. Further details regarding the exceedance are provided in Appendices 2R and 2S.

A sample of treated water from MEL-14 was collected on August 19, 2018. Upon review of the laboratory analysis results, the TDS concentration was found to be 1,430 mg/L which exceeded the permitted discharge limit of 1,400 mg/L. Further details regarding the exceedances are provided in Appendices 2T and 2U.

3.0 SUMMARY OF PREVIOUS BIOLOGICAL MONITORING STUDIES

This report section provides a summary of the results from the 2017 AEMP Annual Report for water quality, sediment quality, BIC, fish health and fish tissue, and plankton biological monitoring studies conducted at Meliadine Lake and/or the Peninsula Lakes. Baseline sampling programs carried out in 2015 and 2016 reflect conditions prior to discharge of the Type A Water Licence (NWB 2016) effluent to the Near-field area of Meliadine Lake. Additional details can be found in the final 2017 AEMP Annual Report (Golder 2018c).

3.1 Water Quality

3.1.1 Meliadine Lake

Water quality data were collected from Meliadine Lake in 2015 (Near-field and Mid-field areas, during the open-water season), 2016 (Near-field and Mid-field areas during open-water and under-ice; reference areas during open-water), and 2017 (Near-field and Mid-field areas during open-water and under-ice; reference areas during open-water). Based on the analyses conducted as part of the 2017 AEMP Annual Report (Golder 2018c), there were differences in water quality of the Near-field area for open-water conditions in 2017 as compared to 2015 and 2016. Under-ice water quality of the Near-field area in 2016 and 2017 was similar (under-ice data were not collected in 2015). Open-water season water quality of the Mid-field and reference areas in 2015, 2016, and 2017 was similar.

Water quality in Meliadine Lake characterized during ice-covered and open-water conditions lacked stratification within the water column and was generally well-oxygenated. Concentration of TDS, hardness, alkalinity, specific conductivity, nutrients, and metals were low and none of the relevant CWQG-PAL, CDWQG, or SSWQO developed for the Mine were exceeded. Specific conductivity, major cations, chloride, sulphate, and some metals (e.g., total arsenic, barium, cobalt, copper, nickel, silicon, and strontium) concentrations were slightly higher in the exposure areas than the reference areas; the Near-field area tended to have slightly higher concentrations compared to the Mid-field area. In addition, specific conductivity, hardness, chloride, major cations, ammonia, and some metals (e.g., barium, boron, copper, strontium) had slightly higher concentrations during ice-covered conditions compared to open-water conditions.

3.1.2 Peninsula Lakes

In general, water quality in the Peninsula Lakes was similar in 2017 compared to 2015 and 2016, and thus all data were considered to be representative of baseline (Golder 2018c). The Peninsula Lakes were well-oxygenated, with pH values indicative of slightly basic conditions, low sensitivity to acid deposition, and low to moderate ionic strength. Parameter concentrations in the Peninsula Lakes were low and none of the relevant guidelines or site-specific objectives were exceeded. Specific conductivity, hardness, and concentrations of TDS (including chloride and sulphate) and some metals (including arsenic, barium, and strontium) in Lake A8 were slightly higher than in the other two Peninsula Lakes. Concentrations of phosphorus, major ions (i.e., bicarbonate and fluoride), and several metals including boron, lithium, molybdenum, selenium, uranium, and vanadium were slightly higher in Lake D7 compared to Lake A8 and Lake B7. Specific conductivity, hardness, alkalinity, TDS, major ions, and some metals including arsenic, barium, lithium, and strontium were generally slightly higher in the Peninsula Lakes compared to Meliadine Lake.

3.2 Sediment Quality

In 2015 and 2016, a total of 35 sediment quality samples from Meliadine Lake, five samples from Lake A8, four samples from Lake B7, and three samples from Lake D7 were collected and analyzed for particle size, total organic carbon, nutrients, and metals. These data form a baseline dataset for comparisons to future monitoring of sediment quality trends during the life of the Mine.

Under baseline conditions, concentrations of arsenic, chromium, and copper exceed guideline values. Arsenic concentrations in Meliadine Lake were generally highest in the Near-field area (MEL-01). Due to the strong relationship between fine sediment content and metal concentrations in Melidine Lake sediments, data were normalized to fine sediment content prior to running statistical tests. Even after normalization, some sediment quality parameters (arsenic, iron, mercury, strontium, and sulphur) were higher in the Near-field area compared to the reference areas. The Mid-field area had similar particle size distribution to the reference areas, but concentrations of some parameters (arsenic, chromium, cobalt, lead, manganese, molybdenum, nickel, uranium, and zinc) were higher in the Mid-field area than in reference areas.

Sediment samples from the Peninsula Lakes were also relatively sandy, with concentrations of arsenic, chromium and copper that exceeded SQGs. The lowest concentrations of these three parameters were observed in Lake B7.

3.3 Benthic Invertebrate Community

Benthic invertebrate communities sampled in Meliadine Lake exposure and reference areas during 2015 and 2016 baseline sampling programs were representative of subarctic systems (Golder 2018c). Benthic invertebrate communities were characterized by low total density and low to moderate richness. Simpson's Diversity Index and evenness values suggested that baseline benthic invertebrate communities sampled at most stations in the reference and exposure areas had moderate to high diversity with few taxa that were overly dominant. Benthic communities were dominated by midges (family Chironomidae), with the tribe Chironomini being the most dominant chironomid group in all areas sampled within Meliadine Lake. Spatial and temporal differences in community structure among Near-field and Mid-field exposure areas and the reference areas were observed during evaluation of the 2015 and 2016 data. In particular, the BIC of the Near-field area was found to differ from communities in the three reference areas in 2016. These differences may have been attributed to potential differences in the physical habitat sampled (i.e., due to substrate type variation), or possibly, mild nutrient enrichment in the Near-field area from the exploration camp STP discharge. Overall, the BIC of the Near-field area was most similar to the community in Reference Area 1.

3.4 Fish Health and Fish Tissue

Baseline fish health and tissue chemistry data were collected in 2015 for Threespine Stickleback (*Gasterosteus aculeatus*) and Lake Trout (*Salvelinus namaycush*) from the Near-field area of Meliadine Lake (Golder 2016a). Threespine Stickleback were subsequently sampled from two reference areas (Reference Areas 1 and 2) in 2017 to complete the fish health and tissue chemistry baseline dataset (Golder 2018c). Threespine Stickleback were captured in sufficient numbers from the Near-field area and reference areas of Meliadine Lake to meet sampling requirements for the fish health and tissue chemistry components of the AEMP. Threespine Stickleback were abundant throughout shallow areas (i.e., less than 3 m) of Meliadine Lake, and susceptible to capture using minnow traps and backpack electrofishing. The majority of Threespine Stickleback captured in Meliadine Lake (i.e., 76% of fish sampled) were infected by the tapeworm *Schistocephalus solidus* that competes with the host for available resources. In general, Threespine Stickleback were similar between the Near-field and reference areas;

however, differences were observed in population structure and tissue chemistry parameters. Threespine Stickleback sampled from the Near-field area were generally larger and exhibited lower metal concentrations in carcass tissue relative to fish sampled from the reference areas.

3.5 Plankton

Plankton monitoring was conducted as a targeted study during the open-water seasons of 2015, 2016, and 2017 (Golder 2018c). Samples of phytoplankton, zooplankton, chlorophyll *a*, and nutrients were collected in five areas of Meliadine Lake (i.e., Near-field and Mid-field areas, and three reference areas). Trophic status calculations indicated conditions in Meliadine Lake were oligotrophic in all areas and years. Higher chlorophyll *a* concentrations and phytoplankton biomass, and unique phytoplankton community structure (based on multivariate analysis) in the Near-field area was suspected indicate the potential effects of nutrient enrichment originating from the exploration camp STP effluent outfall. Although total phosphorus (TP) concentrations were not unusually elevated in the Near-field area, they were highest in this area in September during each year of monitoring. Zooplankton biomass was primarily dominated by cladocerans and rotifers in all areas of Meliadine Lake. This targeted study provided useful information to characterize plankton communities in Meliadine Lake and to inform selection of monitoring tools for incorporation into the AEMP.

4.0 STUDY DESIGN OVERVIEW

The AEMP was designed to harmonize with the EEM requirements of the MDMER throughout the life of the Mine. The Cycle 1 EEM study design (Golder 2017a) and AEMP Design Plan (Golder 2016a) are summarized below.

4.1 EEM

An overview of the Cycle 1 EEM study design is provided in Table 4.1-1. The biological monitoring studies in 2018 included a BIC survey and a small-bodied fish health survey with Threespine Stickleback (*Gasterosteus aculeatus*), with supporting water and sediment quality data collection. A fish tissue survey was not conducted because concentrations of mercury and selenium in effluent did not meet the criteria for initiating a survey as per Schedule 5, Section 9c and 9d of the MDMER. A plume delineation study was conducted during the discharge period to describe effluent mixing in the Near-field area. Effluent quality samples (chemistry and toxicity) were collected by Agnico Eagle as per MDMER requirements (Government of Canada 2018).

Component-specific deviations from the Cycle 1 EEM study design are summarized in Table 4.1-1; additional details and descriptions of how the deviations affected the results interpretations are provided in the corresponding report sections. A key deviation was the change in the Near-field area location. In the Cycle 1 EEM study design (Golder 2017), the exposure area was proposed to be near MEL-D-1. In their comments on the EEM study design, ECCC recommended that the exposure area be relocated to assess the effects of the permanent discharge point (MEL-14), which was implemented during the Cycle 1 EEM study.

Table 4.1-1: Summary of Cycle 1 EEM Study Design

Component	Description	Measurement Endpoints	Target Sample Sizes	Deviations from Study Design	Report Section with Detailed Methods/ Results
Effluent Quality (Chemistry and Toxicity)	Description of effluent quality since the Mine became subject to the MDMER	■ Chemistry: ▪ Deleterious substances as per Schedule 4 of the MDMER ▪ Effluent Characterization as per Schedule 5 of the MDMER ■ Toxicity: ▪ Acute Lethality to Rainbow Trout and *Daphnia magna* ▪ Sublethal toxicity to Fathead Minnows, *Ceriodaphnia dubia, Lemna minor, Pseudokirchneriella subcapitata*	Weekly and quarterly monitoring as per MDMER	Not applicable	Section 2.4.2
Effluent Plume Delineation	Distribution of the effluent plume and percent effluent concentration in the Near-field exposure area	Concentration of effluent at 100 m and 250 m from final discharge point	not applicable	None	Section 2.4.3
Benthic Invertebrate Community	Structure and composition of the benthic invertebrate assemblage	Total invertebrate density, total taxonomic richness, Simpson's diversity index, Simpson's evenness index (SEI), Bray Curtis Index (BCI)	Five stations in each of exposure and reference area	■ Change in Near-field area ■ Petite Ponar grab was used instead of an Ekman grab ■ Change in station where discrete samples were collected for within-station variability assessment	Section 9.0

Table 4.1-1: Summary of Cycle 1 EEM Study Design

Component	Description	Measurement Endpoints	Target Sample Sizes	Deviations from Study Design	Report Section with Detailed Methods/ Results
Fish Population	Lethal and non-lethal fish health survey of Threespine Stickleback	■ Size at age, relative gonad size, condition, relative liver size, age, length-frequency distribution, young-of-the-year abundance ■ Additional supporting endpoints including sex, maturity, life stage, egg weight, fecundity, internal and external abnormalities	■ Lethal survey: 20 males, 20 females, and 20 juveniles from each exposure and reference area ■ Non-lethal survey: an additional 100 fish from each exposure and reference area	■ Change in Near-field area ■ Ages were assigned based on otoliths instead of length-frequency distributions (TAP request) ■ No YOY were captured	Section 10.0
Supporting Data - Water Quality	Physical and chemical characteristics of surface waters	■ Field-measured vertical profiles (dissolved oxygen, pH, water temperature, specific conductivity) ■ Laboratory-measured chemistry (conventional parameters, total metals, radium-226, cyanide)	At least two stations in each of exposure and reference area	None	Section 6.0
Supporting Data - Sediment Quality	Physical and chemical characteristics of bottom sediments	Total organic carbon, particle size, total metals	Five stations in each exposure and reference area	None	Section 8.0

MDMER = Metal and Diamond Mining Effluent Regulations; SDI = Simpson's diversty index; SEI = Simpson's evenness index; BCI = Bray-Curtis Index.

4.2 AEMP

The AEMP consists of two distinct programs: the Meliadine Lake study and the Peninsula Lakes study, with the study design based on Project design, IQ, consultation, and regulatory requirements (Golder 2016a). Based on IQ and community consultation, the importance of clean water and the health of fish and birds were emphasized by the Elders and other people in the communities who rely on these resources for traditional use. Elders have expressed concerns regarding potential Project-related adverse effects on drinkability of water and fish populations in waterbodies of the Meliadine watershed. Key questions were developed for each monitoring component in both studies to focus the study design and to analyze the results in the annual monitoring reports.

The Meliadine Lake study was designed around the key aspects of EEM requirements (e.g., number of stations per area, sample sizes, measurement endpoints and supporting variables), as Meliadine Lake will receive direct effluent discharge. The core components of the Meliadine Lake study are water quality, sediment quality, benthic invertebrate communities, and fish health. A targeted plankton study is also included to investigate the potential for plankton monitoring. For the Meliadine Lake study, up to three within-lake reference areas are included in the study design. Within-lake reference areas were chosen because a different small-bodied fish assemblage was found in Meliadine Lake compared to other lakes in the region, and effects on water quality are expected to be localized; this allows use of reference areas at some distance downstream from the diffuser.

The Peninsula Lakes study was designed to detect potential indirect effects of the Mine (e.g., aerial deposition and physical alteration of watersheds). The core component of the Peninsula Lakes study is water quality. Water quality is monitored on a regular basis, with biological or other studies (i.e., targeted studies) added if the water quality results suggest Mine-related changes have occurred.

Key questions for the Meliadine AEMP are proposed for each core component to focus the study methods, data analyses, and interpretation. The key questions for each study, by component, are provided in Table 4.2-1.

Table 4.2-1: Key Questions Addressed by the Aquatic Effects Monitoring Program

Study	Component	Key Questions
Meliadine Lake	Water Quality	■ Are concentrations of key parameters in effluent less than Water Licence limits? ■ Are concentrations of key parameters in Meliadine Lake consistent with FEIS predictions and less than AEMP Action Levels? ■ Are concentrations in the exposure area increasing over time relative to the reference areas?
	Sediment Quality	■ Are concentrations of sediment quality parameters in Meliadine Lake less than benchmarks? ■ Are concentrations in the exposure area increasing over time relative to the reference areas?
	Benthic Invertebrate Community	■ Is the benthic invertebrate community affected by potential Mine-related changes in water and sediment quality in Meliadine Lake?
	Fish Health	■ Is fish health affected by changes in water and sediment quality in Meliadine Lake?
	Fish Tissue Chemistry	■ Are tissue metal concentrations in fish from Meliadine Lake increasing due to mining activities? ■ Are tissue metal concentrations in fish from Meliadine Lake increasing relative to reference areas or baseline?

Table 4.2-1: Key Questions Addressed by the Aquatic Effects Monitoring Program

Study	Component	Key Questions
Peninsula Lakes	Water Quality	■ Are concentrations of key parameters in the Peninsula Lakes consistent with FEIS predictions and less than AEMP Action Levels? ■ Are concentrations of key parameters in the Peninsula Lakes increasing over time relative to baseline or reference conditions?

An overview of the AEMP study design is provided in Table 4.2-2. In Meliadine Lake, the field programs in 2018 included water quality sampling in Near-field and Mid-field areas during the ice-cover season and in all areas during the open-water season, and sediment quality sampling and benthic invertebreate community surveys in both exposure areas and two reference areas during the open-water season. Additional studies included effluent plume characterization, and a plankton survey as part of the plankton targeted study. Water quality sampling during the open-water season was also conducted in the Peninsula Lakes.

Table 4.2-2: Summary of Aquatic Effects Monitoring Program Study Design

Area	Component	# Stations per Area	# Samples per Station	Parameters	Sample Type	Sampling Frequency	Sampled in 2018?	Report Section with Detailed Methods
Meliadine Lake Exposure Area (Near-field and Mid-field)[a]	Water Quality	5	1	major ions, nutrients, metals	composite; from specific depth	once during under-ice; monthly during open-water discharge period	Yes	Section 6.0

Table 4.2-2: Summary of Aquatic Effects Monitoring Program Study Design

Area	Component	# Stations per Area	# Samples per Station	Parameters	Sample Type	Sampling Frequency	Sampled in 2018?	Report Section with Detailed Methods
Meliadine Lake Reference Area 3 (southwest bay)	Water Quality	5	1	major ions, nutrients, metals	composite; from specific depth	monthly during open-water discharge period	Yes	Section 6.0
		5	1	chlorophyll *a*	composite; from specific depth or depth-integrated	monthly during open-water discharge period	Yes	Section 11.0
	Benthic Invertebrates	5	5	benthic invertebrate taxonomy	composite from 5 grabs	as required		Section 9.0
	Sediment Quality	5	5	particle size, total organic carbon, nutrients, metals	composite grab	as required	Yes	Section 8.0
	Plankton[(b)]	5	1	phytoplankton taxonomy	composite; depth-integrated	as required	Yes	Section 11.0
		5	1	zooplankton taxonomy	composite; vertical tow of water column	as required	No	not applicable
Peninsula Lakes: Lake B7 Lake A8 Lake D7	Water Quality	3	1	major ions, nutrients, metals	composite; from specific depth	twice during open-water season	Yes	Section 7.0

Notes:

(a) Only the Near-field area, and Reference Areas 1 and 2 are planned for sampling fish health and fish tissue chemistry.

(b) Plankton monitoring is not a core component of the AEMP but was planned as a targeted study to evaluate the usefulness of plankton monitoring for future monitoring.

(c) Fish health and tissue chemistry sampling for the AEMP is currently scheduled for 2021.

(d) Sample size is for Threespine Stickleback; Lake Trout sample sizes will be determined prior to next AEMP Fish Health/Tissue Chemistry program.

(e) Lake Trout will not be collected from the Reference Areas.

(f) Reference Area 2 was sampled to provide additional baseline data; further sampling will depend on triggering by water quality results from the Mid-field area or Reference Area 1.

"Metals" include non-metals (e.g. selenium) and metalloids (e.g., arsenic).

6.0 WATER QUALITY – MELIADINE LAKE

In support of the AEMP and Water Licence (2AM-MEL1631) requirements of the Mine, water quality monitoring was completed from 2015 to 2018 in Meliadine Lake (Figure 6.1-1) and Peninsula Lakes (Section 7.0). Beginning in 2018, water quality monitoring was completed at address EEM requirements of the MDMER (Schedule 5, Section 7).

This report section provides a summary of the water quality monitoring programs completed in 2018 at Meliadine Lake, analysis of data collected between 2015 and 2018, and an interpretation of the results per the requirements of the AEMP and EEM. Data analyses presented in this report are based on the AEMP Design Plan (Golder 2016a), and response to comments from ECCC, INAC and KIA during review of the 2017 AEMP Annual Report (Golder 2018a).

6.1 Objectives

The specific objective of monitoring under the AEMP is to characterize water quality conditions in Meliadine Lake so that water quality trends and adaptive management strategies can be identified, as required, during the life of the Mine. The primary objectives of the water quality component of the AEMP, as defined in the AEMP Design Plan (Golder 2016a) are as follows:

- characterize and interpret water quality within Meliadine Lake for the purpose of identifying Mine-related effects and meeting Part 2, Section 7 of the MDMER requirements (Government of Canada 2018)
- verify FEIS predictions (Agnico Eagle 2014), and update them if applicable based on monitoring results
- assess the efficacy of mitigation strategies proposed in the AEMP Design Plan (Golder 2016a) and the Environmental Management and Protection Plan to minimize the water quality effects of the Mine
- recommend appropriate changes to the water quality component of the AEMP for future years
- provide data to inform adaptive management intended to reduce or eliminate Mine-related effects to water quality in Meliadine Lake

As per the EEM (Environment Canada 2012), water quality monitoring was conducted to:

- monitor for changes in environmental conditions in the receiving environment
- provide an indication of temporal or seasonal trends
- evaluate supporting environmental variables to help interpret results from biological monitoring

To meet the primary objectives of the water quality component, analysis and interpretation of water quality data in 2018 were focused on answering two key questions, as defined in the AEMP Design Plan (Golder 2016a):

1) Are concentrations of key parameters in Meliadine Lake consistent with FEIS predictions and less than AEMP Action Levels?

2) Are concentrations in the exposure area increasing over time relative to the reference areas?

The field survey and data analysis methods used to answer the key questions are described in Section 6.2. A summary of quality assurance and quality control (QA/QC) assessment on the 2018 data is provided in Section 6.3. Results and discussion are presented in Section 6.4, where results to meet AEMP requirements are discussed first, followed by results to meet EEM requirements. A summary of the water quality results and conclusions is provided for both the AEMP and EEM in Section 6.5.

6.2 Methods

6.2.1 Sampling Design

The 2018 water quality program was designed to align with the AEMP Design Plan (Golder 2016a) and Cycle 1 EEM Study Design (Golder 2017). The program consisted of one sampling program during ice-covered conditions and two sampling programs during open-water conditions (Table 6.2-1). As a result of a number of site-related factors and field-related occurrences, a few adjustments were made to each program. These included the following:

- Water quality monitoring was not conducted at the former exposure area MEL-D-2 as per the Cycle 1 EEM Study Design (Golder 2017a). In response to ECCC comments on the Cycle 1 EEM Study Design, the EEM exposure study area was relocated to the current AEMP Near-field area to better capture the effects of effluent released from the permanent effluent discharge location (i.e., MEL-14) (Golder 2018d).
- Beginning during the open-water program, four new stations were added in the Near-field area and four historical stations were discontinued (Table 6.2-1). New stations in the Near-field area were selected based on the location of the diffuser, which was installed in 2018. Station locations were redefined based on the as-built location of the diffuser and the results observed during the plume delineation study (Section 2.4.3), with the objective of capturing the water quality within the vicinity of the edge of the mixing zone. Specifically, MEL-01-01 was retained because it had the most historical data, relative to other Near-field stations. The locations of sampling stations MEL-01-06 and 01-07 were selected to meet sampling requirements for stations near the diffuser (i.e., within 100 m) as per ECCC comments on the Cycle 1 EEM Study Design (Golder 2018d). Additional stations MEL-01-08 and 01-09 were selected because they were closer to the mid-basin and away from rocky outcrops that occur closer to shore.
- During the August open-water program, water quality samples were not collected at Mid-field area stations MEL-02-01 or 02-04. Instead, samples were collected at MEL-02-06 and 02-08, which were sediment sample locations. Stations MEL-02-06 and 02-08 are also located within the defined Mid-field exposure area and therefore, this deviation is not expected have affected classification of water quality within this zone.
- Field DO measurements collected at all stations during the ice-cover season and field pH measurements collected at stations MEL-01-01, 01-06, 01-07, 01-08, 01-09, 02-03, 02-05, 03-01, 03-02, 03-03, 03-04, 03-05, 05-03, and 05-05 during the August program were deemed unreliable during the data quality review (i.e., data were anomalous, being well outside the range of previously measured data within exposure and reference areas; Appendix 6A), and were subsequently invalidated. These data were excluded from the analysis. For invalidated pH field data, laboratory pH was used as a surrogate measurement to characterize open-water water quality and in water quality guideline calculation at individual stations. However, as laboratory pH was measured outside the holding time requirement, it is acknowledged that these laboratory pH data have corresponding uncertainty.
- The sampling frequency in 2018 deviated from the frequency requirements of four programs per calendar year as specified under the AEMP Design Plan and MDMER (Section[2][a]) because only three water quality programs were completed (Golder 2016a; Government of Canada 2018). In 2018, water quality monitoring was scheduled for four times per calendar year, but the September water quality program was cancelled due to unsafe boating conditions (i.e., high winds) that prevented safe access to sampling stations.

- Radium-226 was erroneously omitted from the chain-of-custody form for the Travel Blank (T-18-07-01) collected on 23 July 2018 during the July open-water program.

QA/QC procedures described in Section 6.3 and Appendix 6A were followed during the 2018 water quality monitoring program.

6.2.2 Field Methods

6.2.2.1 Sample Location and Sampling Frequency

As per the AEMP Design Plan, five stations in each of the proposed Near-field and Mid-field areas, and Reference Areas 1, 2, and 3 of Meliadine Lake, at a target water depth of 8 to 10 m, were included in the water quality program (Figure 6.2-1). EEM stations included the Near-field area as the EEM exposure area and Reference Area 1 as the EEM reference area. Near-field and Mid-field stations were sampled once during ice-covered conditions and twice during open-water conditions, whereas Reference Area 1 was sampled during each open-water program and Reference Areas 2 and 3 were sampled once during the open-water season (in August). The location and timing of sample collection in 2018 are summarized in Table 6.2-1.

Notes: Samples were analyzed for the required parameters listed in Table 6.2-2, except where noted otherwise. Samples were collected during daylight hours. EEM study areas included the Near-field area and Reference Area 1.

✓ = Sample collected.

A = Station could not be accessed due to weather, no sample collected.

D = Station was discontinued for the 2018 water quality program.

N = New station added for the 2018 water quality program.

E = Water quality samples were collected at the same location as sediment samples resulting in collection of water quality samples at two unplanned locations.

F = Field data were measured but no water chemistry sample was collected.

(a) The total depths recorded during each sampling program were averaged for individual stations, when stations were sampled on more than one occasion.

(b) The average Secchi depth (a measure of water clarity) was calculated based on Secchi depths recorded during each of the open-water (i.e., late spring and summer) sampling programs.

(c) Blank samples (i.e., travel and equipment) were collected.

(d) Sample collection at these locations was missed due to time constraints and/or technical error.

(e) Station MEL-01-06 was sampled approximately 230 m south of the planned location at UTM coordinates of 542907 E, 6988767 N.

(f) Station MEL-02-05 was sampled approximately 140 m north of the planned location at UTM coordinates of 537845 E, 6992831 N.

QC = duplicate quality control samples were collected; - = the site was not included in the sampling plan for a particular field program or was discontinued from the program.

ID = identifier; UTM = Universal Transverse Mercator; NAD = North American Datum.

6.2.2.2 Collection of Supporting Field Measurements

At each sampling station, water depth and physicochemical measurements were collected. Total depth of the water column was measured either by using a sounding line or a boat-mounted sonar unit; during the ice-cover program a sounding line was used to measure total depth. Prior to collecting surface water samples, field measurements of the following four parameters were recorded using a Eureka Manta II multiprobe:

- water temperature (degrees Celsius [°C])
- pH
- DO (in mg/L and percent [%])
- specific conductivity (in microSiemens per centimetre [µS/cm])

In situ physicochemical measurements were taken just below the surface (or below the ice during ice-covered conditions), at 0.5 m below the surface, at 1.0 m below the surface and every 1 m thereafter throughout the water column ending at approximately 0.5 m above the lake bed. During open-water conditions, Secchi depth was measured using a Secchi disk at each station. Secchi disk data were used to provide a coarse estimate of the euphotic zone depth for the purposes of the depth-integrated nutrient sample collection to support the plankton special study (Section 11.0). During ice-covered conditions, ice thickness was measured.

6.2.2.3 Water Sample Collection

Surface water samples were collected as grab samples in accordance with Golder's technical procedures, the Standard Operating Procedures for Water Quality Sampling prepared by Golder, and specific laboratory instructions. Discrete water samples were collected at each sampling station from mid-depth (approximately 4 m) using a Kemmerer sampler. Water for filling ultra-low metals and ultra-low mercury sample bottles were collected with a Teflon Kemmerer sampler, whereas the remaining bottles were filled with water from the polyvinyl chloride (PVC) Kemmerer sampler. At each station, the Kemmerer was triple-rinsed with surface water representative of the station, and then lowered to the required depth (i.e., mid-depth in the water column), triggered by the messenger to collect a sample, returned to the surface, and used to fill the lab-supplied sample bottles. This procedure was repeated until all sample bottles for the station were filled. For the ice-cover program, a pump with tubing extended to the required samples depth was used to collect the samples because the Kemmerer could not be lowered and/or retrieved through the ice.

6.2.3 Laboratory Analysis

Water quality samples collected during the 2018 Meliadine Lake study, with the exception of the radium-226, were analyzed by ALS Environmental Laboratory (ALS; Edmonton and Winnipeg locations). Analysis of radium-226 was subcontracted by ALS Edmonton to ALS in Fort Collins, Colorado, USA. ALS is an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation Inc. (CALA). Specific ALS analytical methods and reported detection limits (RDL) for the required analyses are provided in Appendix 6A.

Water sample bottles were provided by ALS (Section 6.2.2.3). Water samples were processed (i.e., filtered and/or preserved as required, and refrigerated) at site according to the instructions provided by the laboratory. Water samples requiring filtration were filtered through a 0.45 micrometre (µm) Millipore filter in a Nalgene filter tower using a vacuum pump before being preserved with laboratory-provided preservative based on the required analysis. Water samples were kept refrigerated before shipping; ice packs were added to the coolers to keep the samples as cool as possible during transport. Samples were shipped to ALS as soon as possible after sample collection and processing.

Water quality samples were analyzed for the following suite of parameters:

- routine parameters: pH, specific conductivity, hardness, total alkalinity, total dissolved solids [TDS], total suspended solids [TSS], and turbidity
- major ions: bicarbonate, carbonate, chloride, fluoride, sulphate, calcium, magnesium, potassium, sodium, and silica
- nutrients and organics: nitrate, nitrite, total ammonia, total Kjeldahl nitrogen [TKN], total phosphorus [TP], total dissolved phosphorus [TDP], orthophosphate, total organic carbon [TOC], and dissolved organic carbon [DOC]
- total and dissolved metals, metalloids, and non-metals[1]: aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, and zinc
- cyanide (i.e., weak acid dissociable, total, and free)
- radium-226 collected during open-water programs only at the Near-field area and Reference Area 1

The samples were analyzed using laboratory test methods with analytical detection limits (DLs) less than the Canadian Council of Ministers of the Environment (CCME) CWQG-PAL (CCME 1999), and Health Canada CDWQGs (Health Canada 2017). Specific ALS analytical methods and RDL for the required analyses are provided in Appendix 6A.

6.2.4 Data Analysis

Comparisons of key parameters to FEIS predictions, water quality guidelines and normal ranges are provided in this section. Descriptive statistics were calculated and presented for the 2018 dataset by area at the Near-field, Mid-field and reference areas (pooled). Descriptive statistics included the sample size, mean, median, minimum, maximum, and standard deviation. Field data (physicochemical) profiles were compared graphically within each lake area (by showing results for each station) and by season (ice-cover and open-water) to qualitatively evaluate seasonal and vertical patterns. Water temperature, DO concentration and percent saturation, pH, and specific conductivity, were plotted against measured depth. The field measured physicochemical parameters and general water chemistry in each area are discussed for ice-cover and open-water conditions in Section 6.4.2.A quantitativetemporal analysis was conducted for the Near-field area data and discussed in Sections 6.2.4.3.3 and 6.2.4.3.4.

6.2.4.1 Summary Statistics and Comparison to Water Quality Guidelines

Water quality guidelines for the protection of aquatic life are numerical limits or narrative statements based on the most current, scientifically defensible toxicological data available for the parameter of interest, and are designed to be protective of all forms of aquatic life including the most sensitive life stage of the most sensitive species. An exceedance of a guideline does not necessarily imply the likelihood of an adverse environmental effect. Exceedances of guidelines at reference areas indicate naturally elevated concentrations relative to other sites and suggest that resident aquatic biota have adapted to these concentrations. Similarly, water quality results can

[1] Metals, metalloids (e.g., arsenic), and non-metals (e.g., selenium) are referred to as “metals” in this document.

be compared to drinking water guidelines to evaluate if water is safe for consumption by humans or if there is potential risk to human and wildlife health.

Descriptive statistics were calculated from the chemistry data collected from the Near-field, Mid-field and pooled reference areas sampled in 2018. Specifically, mean, median, minimum, maximum values were calculated and compared to acute and chronic CWQG-PAL (CCME 1999) and drinking water quality guidelines and aesthetic objectives (Health Canada 2017). Water quality results from Meliadine Lake stations were also compared to the SSWQO developed for the Mine (Golder 2013). For the mean and standard deviation calculation results below the DL were replace with half DL, when more than 50% of the results were below DL the standard deviation was not calculated.

These guidelines and objectives are summarized in Table 6.2-2; these guidelines, in addition to baseline data, form a starting point for the future monitoring benchmarks.

Table 6.2-2: Water Quality Guidelines and Objectives

Parameter[a]	Unit	CCME Aquatic Life [b]		Health Canada Drinking Water Guideline[c]	Health Canada Aesthetic Objective[c]	Site-specific Water Quality Objective[d]
		Acute	Chronic			
Field Parameters

Other						
Cyanide	mg/L	-	0.005	0.2	-	-

(a) Only parameters with water quality guidelines or an SSWQO are included in this table.

(b) CCME 1999.

(c) Health Canada 2017.

(d) SSWQO developed for the Meliadine Gold Mine (Golder 2013). SSWQOs supersede generic guidelines for review of monitoring and determination of effects.

(e) Lowest acceptable for cold water biota (CCME 1999).

(f) The guideline shown corresponds to a temperature of 10°C and pH of 7.5. For individual samples, the guidelines were calculated based on the specific temperature and pH measured from the sample (CCME 2010).

(g) The list of elements reported for metals analysis includes metalloids such as arsenic and non-metals such as selenium, which are collectively referred to as "total metals" or "dissolved metals" in this table.

(h) The guideline is pH dependent. The 5 µg/L guideline correspond to a pH<6.5 and 100 µg/L corresponds to a pH≥6.5. Guidelines were applied to individual sample based on specific pH measurement taken from the sample.

(i) The guideline is hardness dependent (value shown corresponds to a median hardness of 22.5 mg/L as $CaCO_3$). For individual samples, the guideline was calculated based on the specific hardness measurement taken from the sample.

(j) The acute dissolved zinc guideline is hardness and DOC-dependent. The guideline value shown is the minimum acute guideline calculated using the minimum validated hardness of 13.8 mg/L (as $CaCO_3$) and DOC of 0.3 mg/L. For individual samples, the guideline was calculated based on the specific hardness and DOC measurement taken from the sample. Hardness and DOC values falling outside of the validated range (i.e., hardness 13.8 to 250.5 mg/L as $CaCO_3$ and DOC 0.3 to 17.3 mg/L) were constrained to within the validated range as per CCME guidance (CCME 2018).

(k) The chronic dissolved zinc guideline is hardness, DOC and pH-dependent. The guideline value shown is the minimum chronic guideline calculated using the minimum validated hardness of 23.4 mg/L (as $CaCO_3$) and DOC of 0.3 mg/L and the maximum pH of 8.13; zinc toxicity increases with increasing pH. For individual samples, the guideline was calculated based on the specific hardness, DOC and pH measurement taken from the sample. Hardness, DOC and pH values falling outside of the validated range (i.e., pH 6.5 to 8.13, hardness 23.4 to 399 mg/L and DOC 0.3 to 22.9 mg/L) were constrained to within the validated range as per CCME guidance (CCME 2018).

CCME = Canadian Council of Ministers of the Environment; SSWQO = site-specific water quality objective; DOC = dissolved organic carbon; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; - = no guideline; mg-N/L = milligrams nitrogen per litre; µg/L = micrograms per litre; - = not available.

6.2.4.2 Normal Ranges

The methods for estimating normal ranges for the water quality component of the AEMP follow the methods of Barrett et al. (2015) and are consistent with the approach used for calculating normal ranges for other AEMP components (i.e., sediment, benthos, and plankton). When the baseline data were normally distributed, the normal range was estimated as the 80% prediction interval (PI) of the dataset. Normality was assessed using the Shapiro-Wilk test, using $\alpha = 0.05$ to indicate a significant departure from normality. When the baseline data were not normally distributed, but normality could be achieved after Box-Cox transformation (Box and Cox 1964), the normal range was calculated on the Box-Cox transformed data and the upper and lower bound of the normal ranges were back-transformed. If neither the untransformed data or Box-Cox transformed datasets were normally distributed, the normal range boundaries were defined as the 10th and 90th percentile of the baseline data. In cases where the percentile method was used, a dataset of 1,000 samples was randomly generated from the normal range dataset and the 10th and 90th percentile were calculated from this distribution of 1,000 samples to estimate the normal range. In cases where the lower bound was below the analytical DL, the lower bound was set at the DL.

Prior to calculating the normal range, statistical outliers were identified using studentized residual, which provide a measure of the difference between observed and expected values (i.e., residuals), normalized to the variance of the dataset. Data points with studentized residuals (SR) greater than |3.5| (i.e., more than 3.5 standard deviations from the sample mean), were omitted from analysis. All values at the DL were set to half the DL for the purposes of calculating the normal range.

The provisional normal range concentrations were calculated for Meliadine Lake open-water conditions from pooled reference area (MEL-03, MEL-04, and MEL-05) data collected during the AEMP Monitoring Program between 2016 and 2018 and baseline data collected in Meliadine Lake between 1995 and 2013 (Agnico Eagle 2014). Near-field and Mid-field data collected between 2015 and 2017 were not included in the normal range calculation. Near-field and Mid-field data were screened, and it was determined that they were not suitable for inclusion in the normal range calculation. For ice-covered conditions, provisional normal range concentrations were not calculated because adequate reference and baseline data were not available for the calculation. Additional detail on data screening as part of the normal range calculation is provided in Appendix 6B.

The normal ranges provided in this report are considered provisional during initial monitoring under the AEMP due to the limited sample sizes used in the calculations. The normal range is intended to estimate the range of natural spatial and temporal variability, and the more reference data incorporated into the calculation, the more accurate the estimate becomes. These normal ranges may be re-defined in future reports to allow for the inclusion of additional monitoring data from the reference areas. Normal ranges were not calculated for water quality constituents that were represented by other constituents (e.g., turbidity was not included because it is represented by TSS), or for dissolved metals.

Each calculated normal range was evaluated for representativeness. For example, some parameters had variable RDLs, or parameters with low detection frequency could have calculated normal range upper bound values that were less than the RDL, whereas actual concentrations could be anywhere between zero and the RDL. Therefore, the calculated normal ranges for parameters with non-detect concentrations in the dataset were revised according to the following criteria:

- If all values were less than the RDL, then the lower bound of the normal range was set to zero and the upper bound was set to the RDL value.
- If the lower bound of the normal range was less than the RDL, then it was set to zero.

- If the upper bound of the normal range was less than the RDL, then it was set to the DL value.
- If the dataset included a mix of RDLs and all the values were non-detect, then the normal range was set to zero (lower bound) and the most common used RDL (upper bound).
- If the dataset included a mix of RDLs, and the upper bound of the normal range was between the lowest and highest RDL, then the upper bound of the normal range was set to the highest RDL.
- If the dataset included a mix of RDLs, and the RDLs varied by more than an order of magnitude, then the data with the higher RDL was removed from analysis and the normal range was re-calculated.

The normal ranges are presented in Section 6.4.3.

6.2.4.3 Statistical Analysis

6.2.4.3.1 Overview

Concentrations of water quality parameters in Meliadine Lake were analyzed spatially for 2018 to determine if concentrations in the exposure areas (i.e., Near-field and Mid-field) differed from reference areas (Section 6.2.4.3.2). A qualitative temporal analysis was also conducted to determine if water quality in the Near-field area has changed over the period of the AEMP water quality monitoring program (Section 6.2.4.3.4). A qualitative analysis was also conducted with 2018 Near-field data to determine if there was spatial variability among Near-field stations (Section 6.2.4.3.3).

As part of EEM requirements, water quality in the exposure areas was compared to the references areas to determine if concentrations differed by greater than a factor of two (Section 6.2.4.3.2.2).

6.2.4.3.2 Exposure versus Reference Area Comparison

6.2.4.3.2.1 AEMP Approach

Spatial patterns in 2018 were qualitatively and statistically examined to determine if water quality differed among Near-field and Mid-field exposure areas, and reference areas. Dissolved metals were excluded from spatial analysis because they followed similar trends to total metals. Box plots of water chemistry parameters from Near-field, Mid-field exposure and pooled reference areas for 2018 were visually evaluated for spatial patterns. Additionally, a statistical analysis was conducted to determine if there were significant differences in the concentration of key parameters between exposure and reference areas.

Prior to completing statistical analyses, values below the RDL were substituted with one-half of the RDL. Parameters with greater than 50% of data below RDL were not included in the analysis. Statistical outliers were evaluated using SRs from the analysis of variance (ANOVA) model. A magnitude of |3.5| for the SR was used to identify observations that may be unusual. When an outlier was detected, the validity of the data point was examined. If the outlier was determined to be the result of a data entry error, it was corrected. If the outlier was not the result of data entry errors and could not be resolved otherwise, the analysis was completed with and without the outlier included.

Statistical analysis was conducted separately on ice-cover and open-water datasets. To compare the water quality parameters among areas at Meliadine Lake, an ANOVA test was completed in SYSTAT Version 13.1 (Systat Inc. 2009), followed by post-hoc pairwise comparisons (Tukey's tests; Zar 1999) if the ANOVA test result was significant. Prior to analysis, the water quality data were checked for statistical assumptions (i.e., normality, and homoscedasticity; Zar 1999). If data did not meet the statistical assumptions, the equivalent non-parametric

test (e.g., Kruskal-Wallis [K-W test] with post-hoc Conover-Inman tests; Systat Inc. 2009) were completed. Data were considered significantly different at α (alpha) of 0.1.

Open-water post-hoc statistical comparisons were conducted for Near-field versus Mid-field, Near-field versus pooled reference areas and Mid-field versus pooled reference areas. Open-water data were collected in July and August and pooled for the purposes of the statistical analysis. Ice-cover data statistical comparisons were conducted between Near-field and Mid-field areas.

When significant differences in water quality parameters were observed between sampling areas, the magnitude of difference among the areas (i.e., Near-field, Mid-field and pooled reference) was calculated by expressing the difference as a percentage of the reference mean or median. The area farthest away from the Mine was set as the denominator in the calculation of magnitude of difference. For example, to calculate the magnitude of difference between Near-field and pooled reference areas for a parameter the equation was as follows:

Magnitude: $$Magnitude = \frac{\bar{x}_{NF} - \bar{x}_{Reference\ Areas}}{\bar{x}_{Reference\ Areas}}$$

where $\bar{x}$ is the median or mean (dependent on the statistical analysis). If the statistical comparison between sampling areas was conducted using the K-W test, the data were not considered to be normally distributed and the magnitude was calculated using medians. As the K-W test is a non-parametric method for testing whether samples originate from the same distribution (i.e., it is not a comparison of sample medians), there were instances where the overall K-W test was significant, but no differences in medians were observed.

When spatial patterns were detected (i.e., as significant statistical test results), concentrations of parameters that increased with distance from the Near-field area were categorized as being positive patterns, while parameters with declining concentration with increasing distance were categorized as negative patterns.

6.2.4.3.2.2 EEM Approach

As per the EEM TGD (Environment Canada 2012), a spatial comparison between exposure (Near-field) and Reference Area 1 (EEM reference area) was conducted to identify parameters that differed by more than a factor of two between the two areas. Comparisons were made using the median.

6.2.4.3.3 Spatial Patterns in the Near-field Area

Prior to evaluating if conditions within the Near-field area have changed over time (Section 6.2.4.3.4), the 2018 water quality data at each Near-field station were qualitatively examined for spatial patterns:

- Scatter plots for water chemistry parameters from AEMP stations in the Near-field area were evaluated to identify spatial patterns and trends. The scatter plots were developed to illustrate station data relative to distance from the CP1 diffuser and by station.

Parameters that markedly differed among stations (i.e., by more than a factor of two based on median concentrations) were identified as key parameters and discussed in-text. Detection limits were set as one-half DL when comparing median concentrations. Concentrations of key parameters that increased with distance within the Near-field area were categorized as being positive patterns, while key parameters with declining concentration with increasing distance were categorized as negative patterns. Parameters with greater than 50% of data below RDL were not included in analysis.

6.2.4.3.4 Identification of Temporal Trends

Time series plots of parameter concentrations were completed (Appendix 6F) for Meliadine Lake Exposure and Reference Areas and qualitatively examined to identify increasing trends in 2018 relative to previous AEMP monitoring years (i.e., 2015 to 2017). Temporal trends were first evaluated in the Near-field area and if identified, were further analyzed on temporal box-and-whisker plots by area (Appendix 6G). This analysis was conducted separately for ice-covered and open-water conditions.

6.2.4.4 Comparison to FEIS Predictions

Comparison of Near-field area data for 2018 were compared to applicable model predictions in the FEIS for Meliadine (Agnico Eagle 2014). The FEIS predictions for water quality included an evaluation of water quality in the mixing zone of Meliadine Lake to evaluate potential contaminants of concern. The results of the model predictions indicated that background concentrations of cadmium exceeded CCME guidelines for the protection of aquatic life. It was predicted that the addition of effluent would not increase concentrations of cadmium at the edge of the mixing zone to above background.

Within the mixing zone of Meliadine Lake, FEIS predictions indicated that several parameter concentrations would increase above baseline: TDS, major ions (i.e., chloride, sodium, fluoride and sulphate) and several total metals. To examine this prediction, concentrations at the edge of the mixing zone in the Near-field were compared to FEIS predictions.

In the east bay of Meliadine Lake, the FEIS predictions indicated that TDS and major ions would gradually increase during the construction and operations phases of the Mine; the maximum concentrations are predicted to occur in the last year of the operations phase (i.e., 176, 66, and 19 mg/L TDS, chloride, and sodium, respectively). These predicted maximum concentrations do not exceed guidelines for TDS, chloride and sodium but exceed the range of concentrations observed in Meliadine Lake during baseline.

Concentrations of DO in Meliadine Lake were modelled under construction, operations and closure phases. Predictions indicate that DO concentrations in Meliadine Lake are expected to be above CCME guidelines for the protection of aquatic life (i.e., 6.5 mg/L; CCME 1999) under most conditions. In the mixing zone, it is predicted that DO will fall below the guideline in late summer during the operations phase.

Overall, based on the conceptual diffuser design, the predicted Mine water quality and quantity discharged to Meliadine Lake, and the physical mixing attributes in Meliadine Lake in the vicinity of the diffuser, it was predicted that there will be a minor change in water quality, but that no parameters will exceed CCME guidelines at the edge of the mixing zone. Therefore, no residual impacts from the point source discharge of effluent into Meliadine Lake are anticipated and it is predicted that water quality outside of the mixing zone would support the same uses as during baseline conditions (i.e., safe for aquatic life, safe for use as drinking water, and for recreational activities; Agnico Eagle 2014).

6.3 Quality Assurance/Quality Control

6.3.1 Overview of Procedures

The QA/QC practices applied during this study and detailed results of the QC analyses for discrete water quality samples collected at Meliadine Lake are provided in Appendix 6A. The QA components of the program included the use of trained personnel and an accredited analytical laboratory; QC components included assessments of duplicates and field, equipment, and travel blank samples. Dissolved and total parameter concentrations were also compared.

6.3.2 Summary of Results

Detailed results are provided in Appendix 6A. The results of the review of field and laboratory data indicated that field measurements and laboratory data were of high quality. Key findings from the 2018 QA/QC evaluation are as follows:

- In general, field measurements and results of laboratory samples collected during the 2018 sampling program were within the ranges that would be expected for Meliadine Lake, with the exception of several field pH measurements collected in August. These field pH measurements were invalidated because the values were far outside of the range of historical variation at these stations. DO measurements in the Near-field and Mid-field areas during ice-covered conditions were also far outside the range considered likely (i.e., were in the range of extreme supersaturation). These data were deemed unreliable and excluded from analysis.
- No issues were identified in analytical methods used or units reported by the laboratory.
- Holding times recommended by the laboratory were exceeded for some parameters. The holding time exceedances were not expected to affect data quality for the Meliadine water quality program.
- QC samples (i.e., blanks and duplicates) accounted for approximately 16% of the total number of water samples submitted for analysis.
- The water quality QC sample evaluation indicated that for the combined equipment and travel blanks, 1% of parameters were detected at concentrations more than five times the DL. No notable contamination occurred in the blank samples.
- Approximately 3% of paired concentrations in duplicate discrete water quality samples had a relative percent difference (RPD) of more than 20%. Within-station variability and field precision for the 2018 dataset were rated as low and high, respectively.

The overall quality of the water quality data was rated high. Therefore, the results reported in the report are considered reliable and meet the needs of the program.

6.4 Results and Discussion

6.4.1 Field Measured Physicochemical Parameters

Field physicochemical water column profiles for each of the three water quality sampling periods are presented in Appendix 6C.

During ice-covered conditions (March sampling event) the field profiles followed a similar pattern between Near-field and Mid-field areas. A summary of field profiles for the Near-field and Mid-field areas is presented in Appendix 6C, Tables 6C.2-1 and 6C.2-4 (respectively) and described below:

- Water temperatures were generally consistent among Near-field and Mid-field stations at approximately 0°C below ice cover, and slightly higher (i.e., 1.9°C to 2.6°C) above the lakebed (Appendix 6C, Figure 6C.1-1).
- Water column pH ranged from 7.1 to 8.1 in the Near-field area and 7.2 to 8.0 in the Mid-field area (Appendix 6C, Figure 6C.1-7). In both areas, pH declined with depth. Surface pH was within the acceptable CWQG-PAL range of 6.5 to 9.0 at all stations in the Near-field and Mid-field areas.
- Water column specific conductivity ranged between 102 to 161 µS/cm in the Near-field area and 91 to 126 µS/cm in the Mid-field area. Specific conductivity generally declined with depth (Figure 6C.1-10).

During open-water conditions (July and August sampling events) the field profiles generally followed similar patterns among areas. A summary of field profiles for the Near-field, Mid-field and reference areas is presented in Appendix 6C, Tables 6C.2-2 to 6C.2-11 and described below:

- Water temperature was relatively constant with depth in all areas during the July program, with the exception of the Mid-field area and Reference Area 1, both of which showed a slight decrease in temperature at approximately 5 and 4 m depth, respectively (Figure 6C.1-2). In August, no thermal stratification was observed in any area (Figure 6C.1-3). Surface water temperatures across all areas varied between 8°C to 13°C.
- DO was close to saturated to supersaturated in all areas in July and August, and remained relatively constant through the water column. A greater variability in DO with depth was observed in July, relative to August in all areas (Appendix 6C, Figure 6C.1-5 and 6C.1-6). Surface DO was well above CWQG-PAL of 6.5 mg/L at all stations in the Near-field and Mid-field areas.
- Water column pH ranged from 7.0 to 8.1 in all areas and was consistent with depth in July and August (Appendix 6C, Figure 6C.1-8 and 6C.1-9). Surface pH was within the acceptable CWQG-PAL range of 6.5 to 9.0 at all stations during open-water conditions.
- Water column specific conductivity was constant with depth in all areas in July and August, with the exception of three stations in the Near-field area in July; at MEL-01-07, MEL-01-08, and MEL-01-09 specific conductivity increased between 4 to 7 m depths and then declined in deeper waters (Appendix 6C, Figure 6C.1-11 and 6C.1-12). Water column specific conductivity ranged between 76 to 98 µS/cm in the Near-field area, 69 to 78 µS/cm in the Mid-field area, and 63 to 76 µS/cm in the References Areas.

6.4.2 Water Chemistry

Water chemistry data for discrete samples collected from Meliadine Lake in 2018 are presented in Appendix 6D, Tables 6D-1 to 6D-5. Summary statistics were calculated for each sampling area during ice-cover (Table 6.4-1) and open-water conditions (Tables 6.4-2). Open-water summary statistics were based on pooled data for the July and August sampling programs because water quality variability was low between the two programs. Summary statistics for the reference areas during open-water conditions were calculated used pooled reference area data. Time-series plots for selected parameters of interest are presented in Appendix 6F to illustrate general trends in parameter concentrations in Meliadine Lake.

6.4.2.1 AEMP

6.4.2.1.1 Overview

Lake water quality during ice-covered conditions (Table 6.4-1; Appendix 6D, Table 6D-1 and 6D-2) was characterized as follows:

- low ionic strength (Near-field and Mid-field area median laboratory specific conductivity was 118 and 99 µS/cm, respectively)
- bicarbonate, chloride, calcium, and sodium are the dominant major ions
- basic pH (median field-measured pH in the Near-field and Mid-field areas was 7.6)
- low hardness (median values in the Near-field and Mid-field areas of 36 and 30 mg/L as $CaCO_3$, respectively; this indicates soft water according to the scale of water hardness by McNeely et al. [1979])
- low nutrient concentrations, with median TP and TN concentrations in the Near-field (0.0046 mg-P/L and 0.15 mg-N/L, respectively) and Mid-field (0.0038 mg-P/L and 0.067 mg-N/L, respectively) areas within the range of oligotrophic classification according to the scale of trophic status by Vollenweider (1968)
- low metal concentrations, which were either below detection or below water quality guidelines

In general, lake water quality during the open-water season was characterized as follows (Table 6.4-2; Appendix 6D, Table 6D-1 to 6D-5):

- low ionic strength (median laboratory specific conductivity across all areas ranged from 74 to 85 µS/cm)
- bicarbonate, chloride, and calcium as the major ions
- basic pH (median field-measured pH across all areas ranged from 7.4 to 7.5)
- low hardness (median values across all areas ranged from 21 to 25 mg/L as $CaCO_3$; this indicates soft water according to the scale of water hardness by McNeely et al. [1979])
- low nutrient concentrations, with median TP and TN concentrations across all areas (0.0025 to 0.0035 mg-P/L and 0.18 to 0.24 mg-N/L, respectively) within the range of oligotrophic classification according to the scale of trophic status by Vollenweider (1968)
- low metal concentrations across all areas, which were either below detection or below water quality guidelines

The following sections provide a more detailed analysis of the AEMP water chemistry data collected from each of the lake areas. In particular, notable water quality results (e.g., guideline exceedances) are presented and discussed.

(a) Dissolved oxygen measurements during ice-covered conditions were outside the acceptable range. Data were deemed unreliable and excluded from analysis.

(b) The ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (2.61 mg-N/L) is based on the combination of field pH (7.8) and water temperature (1.5°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. When field pH was not available laboratory pH was used.

(c) Guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.3 to 7.8). The guideline is calculated based on the individual pH for each sample. When field pH was not available laboratory pH was used.

(d) Guideline is pH dependent: 5 µg/L at pH <6.5 and 100 µg/L at pH ≥ 6.5. When field pH was not available laboratory pH was used.

(e) Guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (29.1 to 37.1 mg/L as CaCO3). The guideline is calculated based on the individual hardness value for each sample.

(f) Guideline is for chromium VI.

(g) Guideline is hardness and DOC dependent. The guideline range shown is based on the hardness (29.1 to 37.1 mg/L as $CaCO_3$) and DOC (2.9 to 4.0 mg/L) range observed in the dataset. The guideline is calculated based on the individual hardness and DOC for each sample. All guidelines were calculated within the validated range for hardness (13.8 to 250.5 mg/L as $CaCO_3$) and DOC (0.3 to 17.3 mg/L).

(h) Guideline is pH, hardness and DOC dependent. The guideline range shown is based on the of field pH (7.3 to 7.8), hardness (29.1 to 37.1 mg/L as $CaCO_3$) and DOC (2.9 to 4.0 mg/L). The guideline is calculated based on the individual hardness and DOC for each sample. All guidelines were calculated within the validated range of pH (6.5 to 8.13), hardness (23.4 to 399 mg/L as $CaCO_3$) and DOC (0.3 to 22.9 mg/L). When field pH was not available laboratory pH was used.

Note:

In cases where 50% or more of data were <DL, no mean or standard deviation was calculated.

No concentrations were higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision after comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

CCME = Canadian Council of Ministers of the Environment; SSWQO = site-specific water quality objective; SD = standard deviation; µS/cm = microSiemens per centimetre; NTU = nephelometric turbidity unit; mg/L = milligrams per litre; mg-P/L = milligrams phosphorus per litre; mg-N/L = milligrams nitrogen per litre; µg/L = micrograms per litre; Bq/L = Becquerels per litre; DOC = dissolved organic carbon; $CaCO_3$ = calcium carbonate; WAD = weak acid dissociable; - = no guideline or data not measured.

(a) The ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.22 mg-N/L) is based on the combination of field pH (8.6) and water temperature (11.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. When field pH was not available laboratory pH was used.

(b) Guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.3 to 8.6). The guideline is calculated based on the individual pH for each sample. When field pH was not available laboratory pH was used.

(c) Guideline is pH dependent: 5 µg/L at pH <6.5 and 100 µg/L at pH ≥ 6.5. When field pH was not available laboratory pH was used.

(d) Guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (17.7 to 39 mg/L as CaCO3). The guideline is calculated based on the individual hardness value for each sample.

(e) Guideline is for chromium VI.

(f) Guideline is hardness and DOC dependent. The guideline range shown is based on the hardness (17.7 to 38.7 mg/L as $CaCO_3$) and DOC (2.2 to 3.4 mg/L) range observed in the dataset. The guideline is calculated based on the individual hardness and DOC for each sample. All guidelines fell within the validated range for hardness (13.8 to 250.5 mg/L as $CaCO_3$) and DOC (0.3 to 17.3 mg/L).

(g) Guideline is pH, hardness and DOC dependent. The guideline range shown is based on the of field pH (7.3 to 8.6), hardness (17.7 to 38.7 mg/L as CaCO3) and DOC (2.2 to 3.4 mg/L). The guideline is calculated based on the individual hardness and DOC for each sample. All guidelines fell within the validated range for pH (6.5 to 8.13), hardness (23.4 to 399 mg/L as $CaCO_3$) and DOC (0.3 to 22.9 mg/L). When field pH was not available laboratory pH was used.

Note:

In cases where 50% or more of data were <DL, no mean or standard deviation was calculated.

No concentrations were higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision after comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

CCME = Canadian Council of Ministers of the Environment; SSWQO = site-specific water quality objective; SD = standard deviation; µS/cm = microsiemens per centimeter; NTU = nephelometric turbidity units; mg/L = milligrams per litre; mg-P/L = milligrams phosphorus per litre; mg-N/L = milligrams nitrogen per litre; µg/L = micrograms per litre; Bq/L = Becquerels per litre; DOC = dissolved organic carbon; CaCO3 = calcium carbonate; WAD = weak acid dissociable; - = no guideline or data not measured.

6.4.2.1.2 Exposure versus Reference Area Comparison

The results of the statistical analysis (with outliers excluded) are presented in Tables 6.4-3 (ice-cover) and 6.4-4 (open-water). Statistical outliers and the results of the statistical tests with outliers included (where applicable) are presented in Appendix 6E. In all cases, outliers were not the result of data entry errors. The outcome of the statistical test with and without outliers included was the same for all parameters except for TKN and total lead during ice-covered conditions. These results are discussed in more detail below.

Spatial patterns during ice-covered conditions were detected for 45 of 55 water quality parameters (Table 6.4-3). Spatial patterns during open-water conditions were detected for 43 of 51 water quality parameters (Table 6.4-4). Time-series plots are presented in Appendix 6F and were qualitatively examined to identify if similar spatial patterns were present in years prior to 2018. The following sections discuss water chemistry and the results of the spatial analysis among exposure and reference areas in more detail.

Field Parameters

Median pH was similar between ice-cover and open-water conditions, whereas conductivity and DO were generally higher during ice-covered conditions (compared to open-water conditions), and temperature was lower during ice-covered conditions (compared to open-water conditions) (Tables 6.4-1 and 6.4-2). Field and laboratory pH in all areas was within the acceptable range for the CWQG-PAL.

A negative spatial trend was detected for field specific conductivity and a positive spatial trend was detected for DO (mg/L) in 2018. Specific conductivity was significantly higher in the Near-field relative to Mid-field (ice-cover and open-water) and reference areas (open-water). A similar spatial trend was observed in 2016 and 2017. Field DO concentrations in all areas during open-water conditions were above the minimum acceptable limit (i.e., 6.5 mg/L) based on the CWQG-PAL.

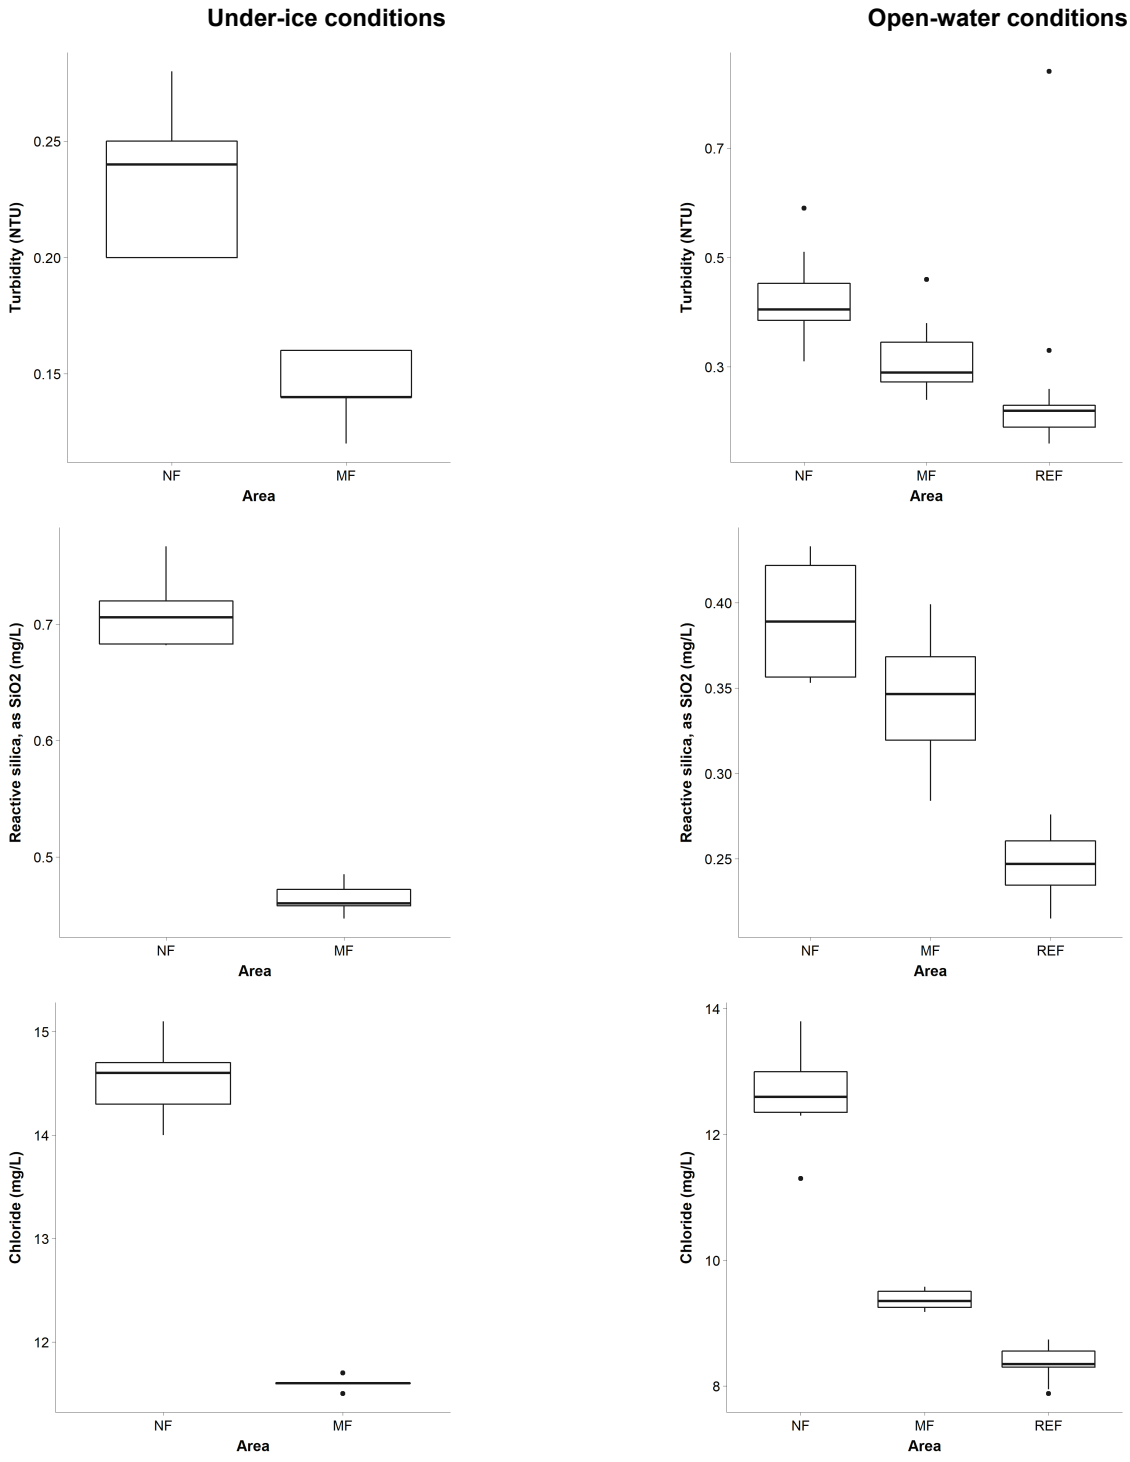
Conventional Parameters

Specific conductivity, water hardness and total alkalinity (as $CaCO_3$) in Meliadine Lake were elevated during ice-covered conditions (ranging from 98 to 122 µS/cm, 29 to 37 mg/L, and 25 to 28 mg/L, respectively) compared to open-water conditions (ranging from 63 to 91 µS/cm, 18 to 39 mg/L, and 15 to 21 mg/L, respectively; Table 6.4-1). Salt exclusion during ice formation can result in elevated ions and conductivity under-ice (Agnico Eagle 2014). A similar phenomenon was observed in previous monitoring years and during baseline monitoring in Meliadine Lake (Agnico Eagle 2014; Golder 2018c).

Median concentrations of TDS in 2018 ranged from 45 to 68 mg/L (Tables 6.4-1 and 6.4-2). Similar to hardness and total alkalinity, TDS was elevated during ice-covered conditions in the Near-field and Mid-field areas in 2018, relative to previous years, but was within the range of concentrations observed in previous years during open-water conditions (Golder 2018c). However, all TDS concentrations in 2018 were well below the Health Canada aesthetic objective of 500 mg/L (Health Canada 2017). Concentrations of total suspended solids (TSS) were all less than DL, with the exception of a single measurement in the Mid-field area in August (Appendix 6D, Table 6D-2).

Negative spatial patterns were detected in 2018 for specific conductivity, hardness, TDS and turbidity. Concentrations were highest in the Near-field, followed by the Mid-field (under-ice and open-water) and lowest in the reference areas (open-water), with the exception of TDS. TDS concentrations did not significantly differ between the Mid-field and reference areas. Similar spatial patterns were observed in 2016 and 2017, although the relative difference in concentration of specific conductivity and hardness among areas appears to have increased over the duration of the AEMP monitoring program. A positive spatial pattern was detected for total alkalinity;

concentrations were significantly lower in the Near-field area relative to the Mid-field and reference areas but did not significantly differ between Mid-field and reference areas. Turbidity had the highest magnitude of difference among areas during ice-covered and open-water conditions (Tables 6.4-3 and 6.4-4; Figure 6.41).



Major Ions

Generally, concentrations of major ions measured in 2018 were within similar ranges as those measured in previous three years (Appendix 6D). Bicarbonate, chloride, and calcium were the dominant ions during both ice-cover and open-water conditions (Tables 6.4-1 and 6.4-2); carbonate was non-detectable in all samples. Similar to 2017, major ion concentrations in 2018 were elevated under-ice, relative to open-water, but overall, concentrations in 2018 were slightly higher under-ice relative to 2017 (Golder 2018c). Similar to previous years, chloride, fluoride, sodium and sulphate were all below applicable CWQG-PAL, CDWQG and aesthetic objectives, and SSWQOs in all areas during ice-cover and open-water conditions (Tables 6.4-2 and 6.4-2).

Negative spatial patterns were detected for all major ions during ice-covered and open-water conditions, except bicarbonate and fluoride (open-water only) (Tables 6.4-3 and 6.4-4). Concentrations were highest in the Near-field, followed by the Mid-field (under-ice and open-water) and lowest in the reference areas (open-water). Positive spatial patterns were detected for bicarbonate and fluoride, with higher concentrations in the Mid-field (bicarbonate only) and reference areas relative to Near-field.

Spatial patterns of chloride, magnesium and sodium in 2018 were similar to 2016 and 2017 (i.e., higher in the Near-field, then Mid-field and lowest in the reference areas), although the relative difference in concentration of these ions among areas appears to have increased during the duration of the AEMP monitoring program. Reactive silica similarly varied among areas in 2016 and 2017, relative to 2018. Based on the time-series plots (Appendix 6F), there was higher variability in sulphate concentrations among areas in 2017, relative to 2018 and 2016; sulphate spatial patterns were similar in 2016 and 2018.

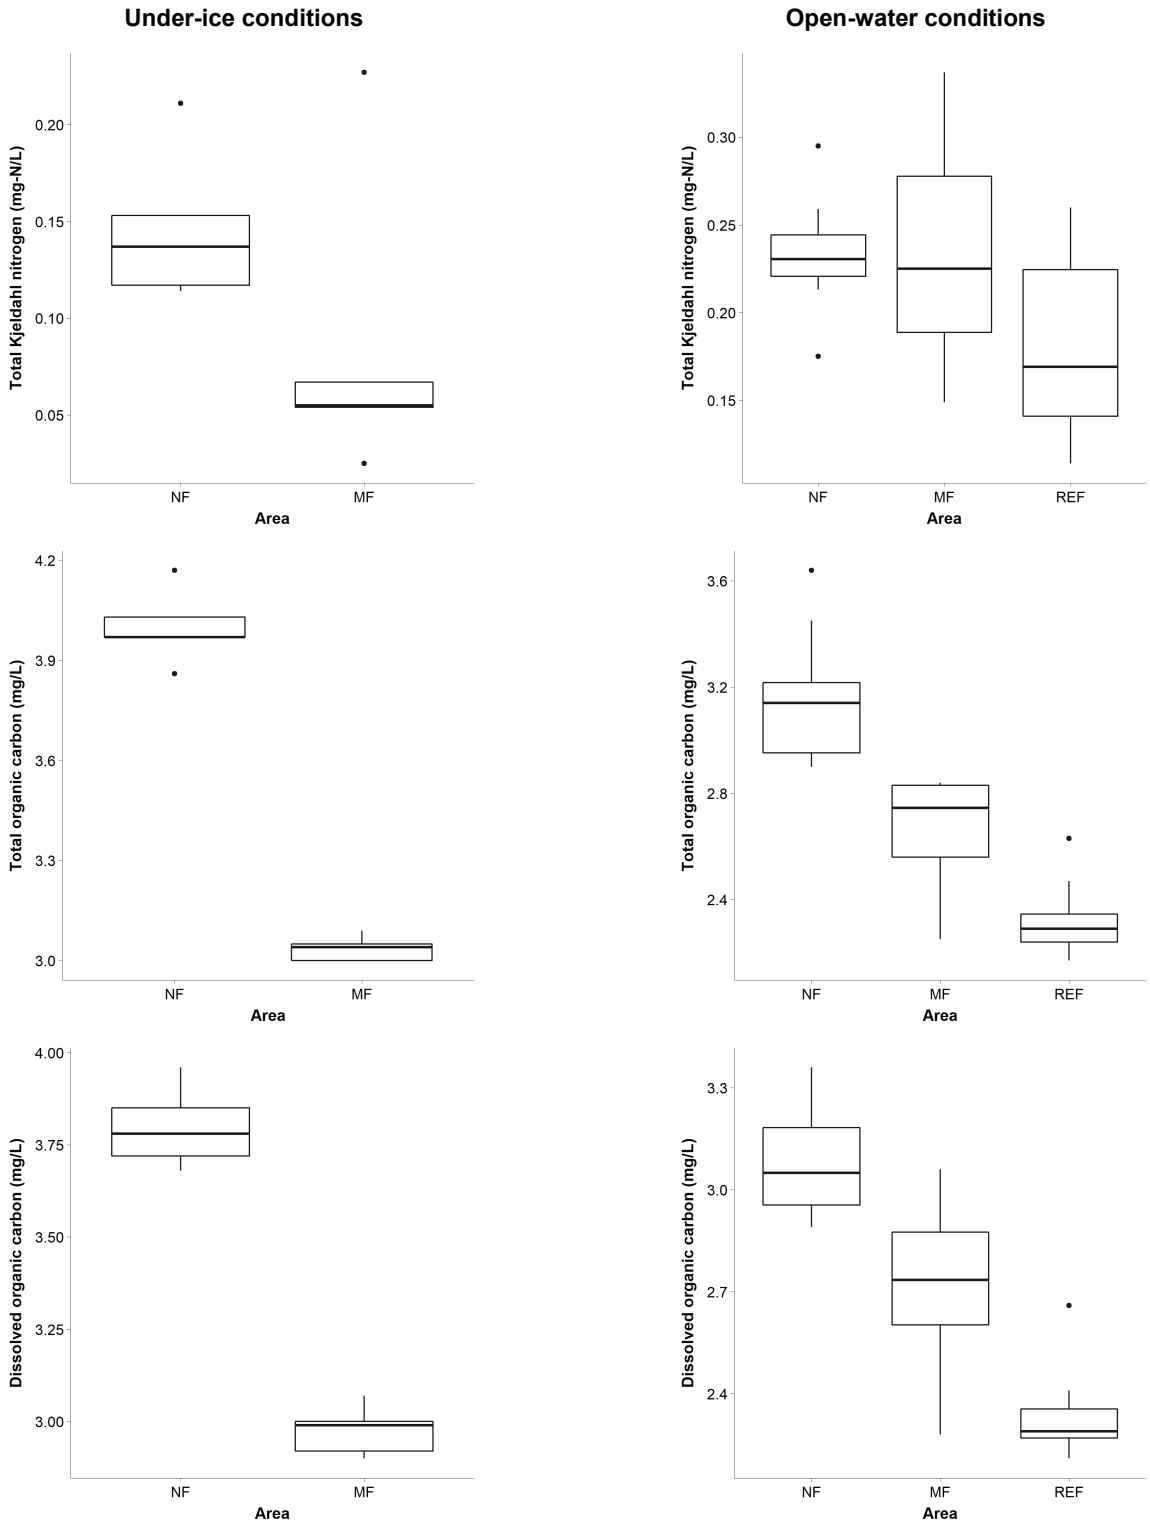
During ice-covered conditions, reactive silica had the highest magnitude of difference between Near-field and Mid-field areas (Figure 6.41). In open-water, the magnitude of difference was highest for chloride and reactive silica concentrations in the Near-field area, relative to the Mid-field and reference areas (Figure 6.41). Although significantly higher ion concentrations were observed in the Near-field area relative to Mid-field and reference areas, the concentrations were orders of magnitude below the generic and conservative guidelines and are therefore, not ecologically relevant.

NF = Near-field Area; MF = Mid-field Area; REF = pooled Reference Area data; mg/L = milligrams per litre; NTU = Nephelometric Turbidity Units; SiO_2 = silicon dioxide.

Figure 6.4-1: Box-and-Whisker Plots for Selected Conventional and Major Ion Parameters with Spatial Patterns Among Areas in Meliadine Lake, 2018

Nutrients

Nutrient concentrations in 2018 were low and generally consistent with previous years (Golder 2018c). Median nitrate concentrations under-ice in the Mid-field area were higher (median 0.012 mg/L) relative to concentrations observed during open-water conditions, which were below detection (i.e., <0.005 mg/L). The opposite was true in the Near-field area, with lower concentrations under-ice (median 0.0089 mg/L), relative to open-water (0.012 mg/L). Nitrite was below detection during ice-covered and open-water conditions in all areas (i.e., <0.001 mg/L), with the exception of open-water concentrations in the Near-field area (range <0.001 to 0.0017 mg/L). Nitrate and nitrite concentrations were below CWQG-PAL and CDWQG and aesthetic objectives (Table 6.4-2).



Total ammonia concentrations were low in 2018, ranging from <0.005 to 0.029 mg-N/L (Tables 6.4-1 and 6.4-2). Similar to previous years, total ammonia concentrations in the Near-field and Mid-field areas were elevated in ice-covered relative to open-water conditions. However, concentrations under-ice in 2018 were not as high as observed in previous years (Golder 2018c). All detected ammonia concentrations were below the CWQG-PAL.

Concentrations of TKN were similar to previous years and were slightly lower under-ice compared to open-water conditions (i.e., <0.05 to 0.23 mg-N/L and 0.11 to 0.34 mg-N/L, respectively; Golder 2018c). Concentrations of TP and TDP in 2018 were similar to previous years, ranging from <0.001 to 0.02 mg-P/L and <0.001 to 0.003 mg-P/L, respectively (Tables 6.4-1 and 6.4-2; Golder 2018c).

Similar to 2017, organic carbon in 2018 occurred primarily in the dissolved form (Golder 2018c). Concentrations of TOC and DOC in 2018 were within ranges observed in previous years, at 2.2 to 4.2 mg/L and 2.2 to 4.0 mg/L, respectively. Median TOC and DOC concentrations were slightly higher in the Near-field and Mid-field areas during ice-covered conditions relative to open-water (Tables 6.4-1 and 6.4-2).

During ice-covered conditions, negative spatial patterns were detected for TKN, TN, TP, TOC and DOC, whereas positive spatial patterns were detected for nitrate, nitrate and nitrite, and total ammonia; the greatest magnitude of difference between Near-field and Mid-field concentrations under-ice was observed for TKN, TN, and TOC (Table 6.4-3; Figure 6.4-2). With an outlier from the Mid-field area (0.227 mg/L) included in the analysis, the outcome of the statistical test changed for TKN; no significant difference was detected during ice-covered conditions between Near-field and Mid-field areas (Appendix 6E).

During open-water conditions, fewer nutrient parameters were statistically analyzed because several parameters had >50% of measurements below DL. TP and TDP were not significantly different among areas in 2018 and showed similar spatial patterns as 2016 and 2017; however, median concentrations of TP in 2018 were higher in the Near-field area (0.0045 mg-P/L), relative to the Mid-field area (0.0025 mg-P/L), and the pooled reference areas (0.0032 mg-P/L; Table 6.4-4). Negative spatial patterns were detected for TKN, TOC and DOC. Spatial patterns for TKN, TOC, and DOC in 2018 were similar to 2017; no patterns were observed in 2016. The highest magnitude of difference among areas was observed for TKN between Near-field and reference areas and Mid-field and reference areas, and for TOC and DOC, between Near-field and reference areas (Figure 6.4-2).

NF = Near-field Area; MF = Mid-field Area; REF = pooled Reference Area data; mg-N/L = milligrams nitrogen per litre; mg/L = milligrams per litre.

Figure 6.4-2: Box-and-Whisker Plots for Selected Nutrient Parameters with Spatial Patterns among Areas in Meliadine Lake, 2018

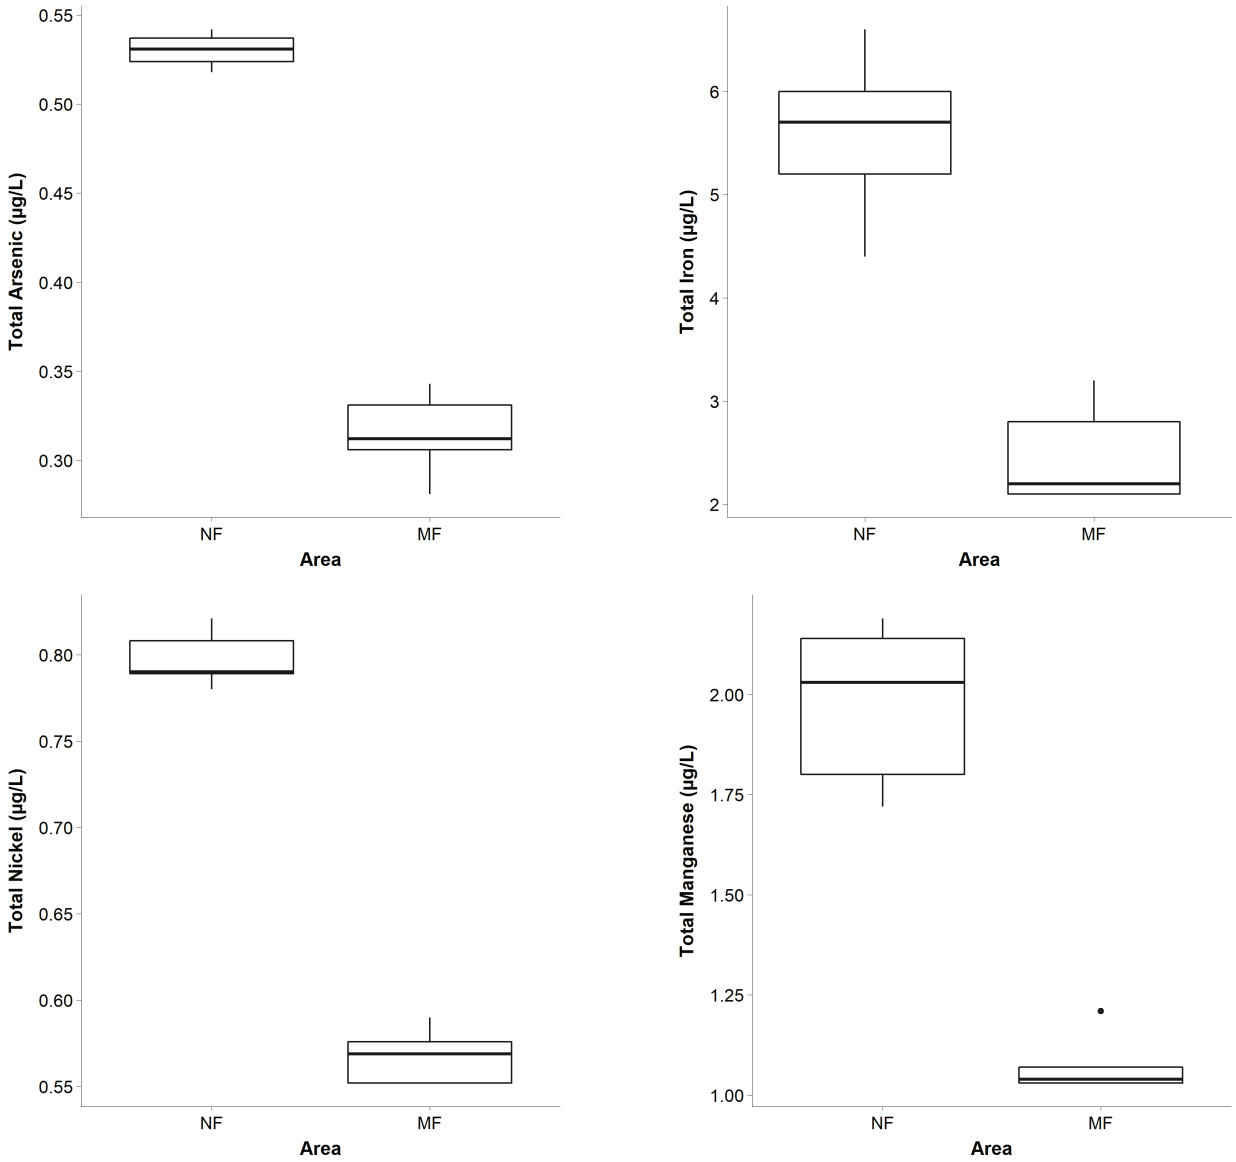
Metals

Total and dissolved metals analyzed in 2018 were detected in most samples, but concentrations were generally low. Metals were analyzed using DLs below applicable guidelines and SSWQOs, and all detected metal concentrations in 2018 were lower than applicable CWQG-PAL, CDWQG and aesthetic objectives, and SSWQOs (Tables 6.4-1 and 6.4-2).

Several metals were detected below the DL in all samples, including total antimony, beryllium, bismuth, cadmium, silver, and thallium, as well as dissolved beryllium, bismuth, cadmium, silver, thallium, and titanium. Total chromium, tin, titanium, vanadium and dissolved antimony, chromium, tin and vanadium were not detected in any sample collected during ice-covered conditions but were detected in some samples during open-water conditions (Appendix 6D, Tables 6D-1 to 6D-5). All total and dissolved metal concentrations were well below applicable CWQG-PAL, CDWQG and aesthetic objectives, and SSWQOs in 2018 (Tables 6.4-1 and 6.4-2).

In general, metals were primarily in the dissolved form (i.e., ratio between total and dissolved metals was less than two) in all areas during ice-cover and open-water conditions except for aluminum, iron and manganese. The ratio between total and dissolved metal concentrations for total aluminum, iron, and manganese was greater than two in all areas during ice-cover and open-water conditions suggesting that a greater relative fraction of these metals occurs as particulate matter rather than dissolved.

Several total metals were excluded from statistical analysis because the datasets contained >50% of concentrations below DL. During ice-covered conditions, negative spatial patterns were detected for total arsenic, barium, boron, copper, iron, manganese, mercury, nickel, strontium and uranium (Table 6.4-3). Median concentrations of total uranium in the Near-field (0.018 µg/L) and Mid-field (0.015 µg/L) areas were just above the DL (i.e., 0.01 µg/L) and therefore, the statistical variability in concentrations between these areas may be a result of analytical variability associated with measuring low analyte concentrations. Total aluminum, lead, molybdenum, and selenium were not significantly different between Near-field and Mid-field areas during ice-covered conditions. The magnitude of difference between Near-field and Mid-field area concentrations under-ice was highest for total arsenic, iron, manganese, and nickel (Figure 6.4-3). With an outlier from the Near-field area (0.107 µg/L) included in the analysis, the outcome of the statistical test changed for total lead; a significant negative spatial pattern was detected during ice-covered conditions between Near-field and Mid-field areas (Appendix 6E).

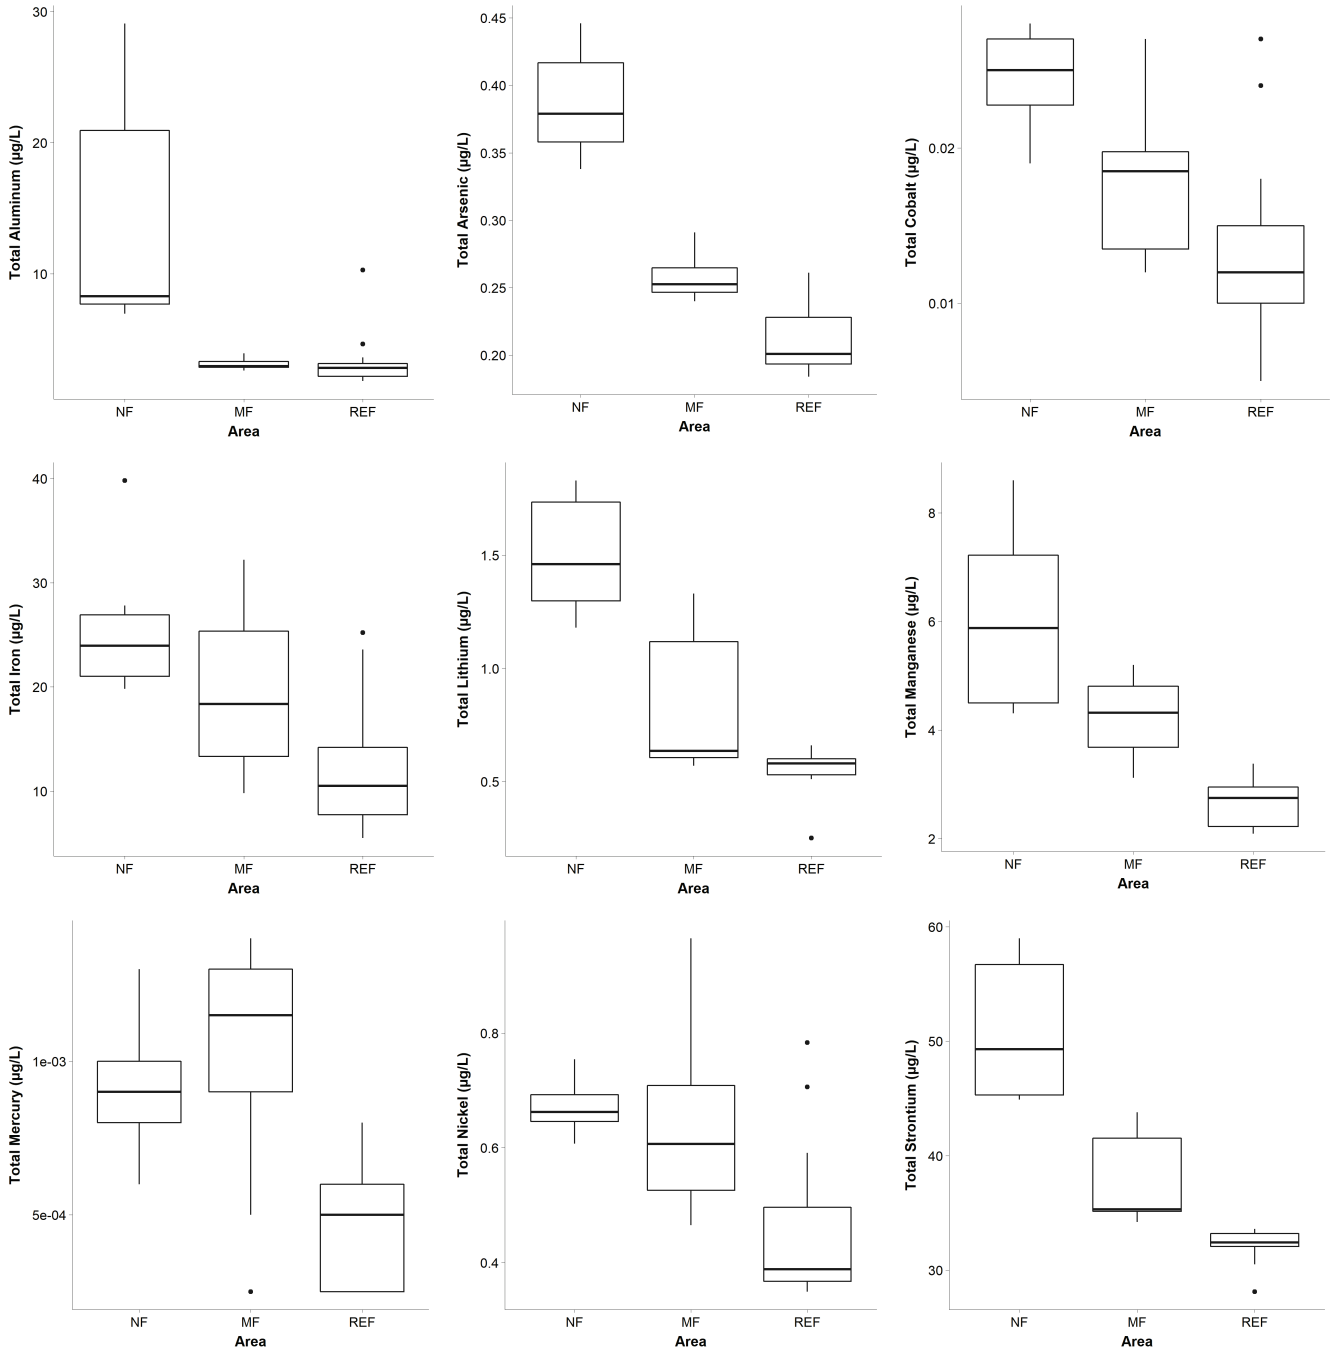


Spatial patterns among areas in 2018 were similar for total barium, copper, iron, and manganese relative to 2016 and 2017. Spatial patterns among areas in 2018 for total arsenic, mercury, nickel, strontium and uranium were also similar to 2016 and 2017, except that in 2018 the relative differences in concentration among areas appear to have increased.

During open-water conditions, negative spatial patterns were detected for total aluminum, arsenic, barium, boron, cobalt, copper, iron, lithium, manganese, mercury, nickel, strontium, and uranium (Table 6.4-4; Figure 6.4-5). Total molybdenum did not significantly differ among areas. Median concentrations of total cobalt and uranium in the Near-field, Mid-field and reference areas were just above their respective DLs (i.e., 0.01 and 0.01 µg/L, respectively) and therefore, the statistical variability in concentrations between these areas may be a result of analytical variability associated with measuring low analyte concentrations (Table 6.4-4). Significant differences in concentrations were observed among all areas for these metals, with the following exceptions: total aluminum and copper did not differ significantly between Mid-field and reference areas, and mercury did not differ significantly between Near-field and Mid-field areas.

Spatial patterns during open-water conditions in 2018 for arsenic, barium, cobalt, copper, iron, and manganese were similar to those observed in 2016 and 2017. Concentrations of total aluminum, and lithium were variable among areas in 2016 and 2017, with spatial patterns emerging in 2018. In 2017, total boron and uranium had similar spatial patterns as 2018, but no spatial pattern was observed in 2016. Spatial patterns of total strontium were similar in 2016, 2017 and 2018, but the relative differences in concentration among areas appear to have increased in each successive sampling year.

Cyanide



Free and weak acid dissociable cyanide species measured in 2018 were below the analytical DL for all stations and sampling events (Tables 6.4-1 and 6.4-2). Detection limits for cyanide species were lower than the applicable guidelines (i.e., 0.005 mg/L, CCME 1999).

NF = Near-field; MF = Mid-field; µg/L = micrograms per litre.

6.4.2.2 EEM

6.4.2.2.1 Comparison to Canadian Water Quality Guidelines

For the purposes of the EEM, the results of the comparison to CWQG-PAL (CCME 1999) are summarized below.

- All samples collected in the Exposure Area (i.e., Near-field) and Reference Area (i.e., Reference Area 1) during the 2018 EEM program were below CWQG-PAL (Table 6.4-2).

6.4.2.2.2 Exposure versus Reference Area Comparison

The EEM TGD (Environment Canada 2012) recommends that a comparison of water quality data be conducted between the exposure and reference areas. In particular, parameters that are greater than a magnitude of two in the exposure area should be identified. A summary of the parameters where exposure area median concentrations (Near-field; MEL-01) were more than two times greater than the reference area (Reference Area 1; MEL-03) concentrations is provided in Table 6.4-5.

Table 6.4-5: Comparison of Near-field (Exposure Area) and MEL-03 (Reference Area) Water Quality, 2018

Sampling Period	Exposure Area Concentrations More than Two Times Greater than the Reference Area Concentrations	
Open-water[a]	Routine Parameters	none
	Major Ions	none
	Nutrients	Nitrate[b] and nitrate plus nitrite[b]
	Total Metals	aluminum, arsenic, lithium, manganese, titanium[b]
	Dissolved Metals	aluminum, arsenic, cobalt[b], lithium

Notes:

(a) Data were pooled from the 19 to 25 July and the 15 August to 2 September 2018 programs.

(b) The MEL-03 (reference area) parameter concentrations were below reported detection limits; comparison to corresponding Near-field area concentrations were based on setting values below detection to half the reported detection limit.

Environment Canada (2012) recommends that for parameters with exposure area medians more than two times greater than the reference area means, the Mine estimate the geographic extent for which this condition exists. This recommendation also provides supporting information for biological monitoring results. An assessment of the treated effluent plume was completed during this EEM cycle and can be used to estimate the geographic extent of these conditions based on the measured Mine effluent mixing zone (Section 2.4.3). As discussed in Section 2.4.3, the geographic extent of the plume extended to sampling stations located 100 m away from the diffuser but did not extend to stations located 250 m away from the diffuser. Therefore, the conditions for water quality parameters present in the Near-field area at concentrations two times higher than the Reference Area is unlikely to persist beyond 250 m distance from the effluent diffuser.

6.4.3 Comparison to Normal Range

Meliadine Lake Near-field mean/median concentrations were higher than their respective normal range upper bound concentrations during open-water conditions for field pH, specific conductivity, hardness, TDS, calcium, chloride, magnesium, potassium, sodium, sulphate, reactive silica, nitrate, total aluminum, arsenic, barium, cobalt, iron, lithium, manganese, mercury, nickel, and strontium (Table 6.4-6). Meliadine Lake Mid-field mean/median concentrations were higher than their respective normal range upper bound concentrations during open-water conditions for specific conductivity, hardness, TDS, chloride, magnesium, sodium, sulphate, reactive silica, total arsenic, barium, iron, manganese, mercury, nickel, and strontium. Meliadine Lake pooled reference area mean/median concentrations fell within their respective normal range for all parameters in 2018.

Table 6.4-6: Normal Ranges for Selected Water Quality Parameters during Open-water Conditions in Meliadine Lake and Comparisons of 2018 Results to Normal Ranges

Parameter	Unit	Detection Limit	Sample Size	Outliers Removed	Baseline Years	AEMP Reference Years	Calculation Method	Normal Ranges		2018 Mean/Median[a]		
								Lower Bound	Upper Bound	Near-field	Mid-field	Reference Area[b]

(a) Lake area means were calculated using the back-transformed mean when the normal range was defined as the prediction interval using Box-Cox transformed data. The arithmetic mean was used when the normal range was defined using untransformed data. The median was used when the calculation method was Percentile. When normal range could not be calculated because the dataset contained too many values below DL, the median was used.

(b) Reference area data were pooled from Reference Areas 1, 2, and 3.

(c) Detection limit for laboratory pH is provided.

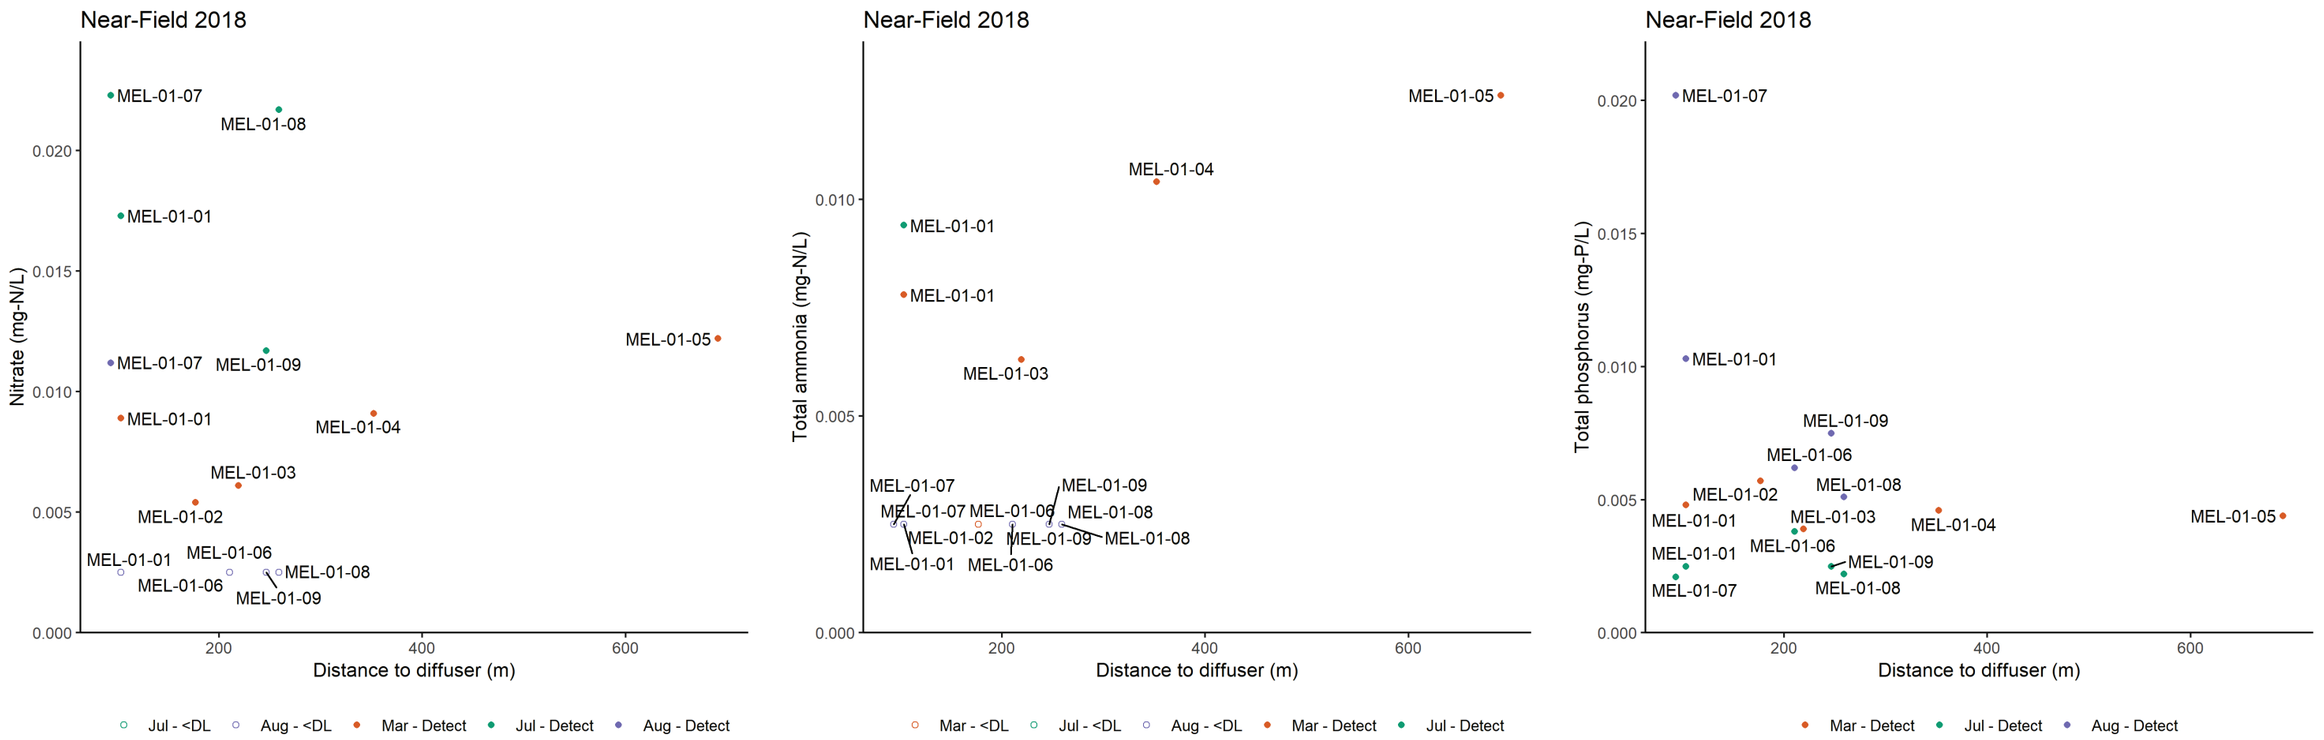
(d) The lower bound of the normal range was less than the detection limit; therefore, the lower bound of the normal range was set to zero.

(e) The upper bound of the normal range was less than the detection limit; therefore, the upper bound of the normal range was set to the detection limit.

(f) All values in the dataset were non-detect; therefore, the normal range was set from zero to the detection limit.

Bolded concentrations exceed the upper bound of the normal range.

Percentile = 2.5th and 97.5th percentiles; PI= 80% prediction intervals; PI(λ) = 80% prediction interval on Box-Cox transformed data.



mg/L = milligrams per litre; µS/cm = microSiemens per centimetre; NTU = nephelometric turbidity unit; mg‑N/L = milligrams nitrogen per litre; mg‑P/L = milligrams phosphorus per litre; µg/L = micrograms per litre; - = baseline data were unavailable and/or normal range could not be calculated because all values in the dataset were below detection.

6.4.4 Spatial Patterns in the Near-field Area

Visual assessment was used to evaluate spatial trends in water quality in the Near-field area in relation to the CP1 diffuser in Meliadine Lake. Positive and negative spatial patterns were detected for a few water quality parameters during ice-covered and open-water conditions in the Near-field area.

Variability among stations in the Near-field area was low overall (i.e., less than two-fold differences in concentrations) for conventional parameters (e.g., specific conductivity, TDS, hardness) and major ions during ice-covered and open-water conditions. Spatial patterns within the Near-field area were observed for nitrate and total ammonia during ice-covered conditions (selected parameters are shown in Figure 6.4-5). Concentrations of these parameters were lower at stations in closer proximity to the diffuser (i.e., MEL-01-02 and 01-03), relative to stations located farther away (i.e., MEL-01-04 and 01-05), with the exception of nitrate at station MEL-01-01; at this station, concentrations of nitrate were similar to MEL-01-04 and 01-05. In general, concentrations of nitrate and total ammonia were higher at MEL-01-05, which is located the farthest west of the Near-field stations. Sampling at this station was discontinued in July 2018. Total and dissolved lead concentrations were variable (i.e., by more than two-times) among Near-field stations but a spatial pattern was not observed with distance from the diffuser.

During open-water conditions, the only within Near-field spatial pattern observed was for total phosphorus (Figure 6.4-5). A weak negative spatial pattern was observed for total phosphorus with concentrations decreasing with distance from the diffuser for the August samples only; a within Near-field area spatial pattern was not observed in July. Nitrate, total aluminum, lead, and dissolved aluminum concentrations were variable (i.e., by more than two-times) among Near-field stations but a spatial pattern was not observed with distance from the diffuser.

MEL-01 = Meliadine Near-field Station; mg-N/L = milligrams nitrogen per litre; mg-P/L = milligrams phosphorus per litre; OW = open-water; UI = under-ice.

Figure 6.4-5: Scatter Plots for Selected Parameters with Spatial Patterns Observed in the Near-field Area, 2018

6.4.5 Investigation of Temporal Trends

Water quality data within Meliadine Lake were qualitatively examined for temporal patterns on temporal box plots presented in Appendix 6G. If observed, trends were further evaluated in temporal box-and-whisker plots presented in Appendix 6G.

Ice-cover Season

Temporal patterns were observed for most conventional parameters, nutrients, major ions and total metals in the Near-field area during ice-covered conditions. Temporal trends were not observed for field and laboratory pH, turbidity, fluoride, sulphate, nitrite, nitrate, total ammonia, total aluminum, antimony, boron, cobalt, manganese, molybdenum, nickel, and lead.

Temporal patterns detected during ice-covered conditions in the Near-field were as follows:

- Gradual increases in each consecutive year were observed in the Near-field area for specific conductivity, hardness, TDS, turbidity, TOC, DOC, calcium, chloride, magnesium, potassium, reactive silica, sulphate, total arsenic, mercury, molybdenum, nickel, selenium, and strontium. Similar trends were observed in the Mid-field area, except that concentrations were generally lower relative to the Near-field area (especially in 2018).
- Step-trend increases were observed in 2018 in the Near-field area for total alkalinity, bicarbonate, sodium, barium, and copper. Similar trends were observed in the Mid-field, with the exception of total copper.
- Step-trend increases in 2017 persisting to 2018 was observed for TP and total uranium.
- TKN, total iron and lithium decreased in 2018, relative to 2016 and 2017. Similar temporal trends were observed in the Mid-field area. Total manganese decreased in 2017 (Near-field) or 2018 (Near-field and Mid-field) relative to 2016.

Of note, despite temporal trends for several parameters in the Near-field area under-ice between 2016 and 2018, all concentrations were well below applicable water quality guidelines in 2018 (Section 6.4.2.1.2), and therefore, below concentrations anticipated to result in adverse effects on aquatic life.

Open-water Season

Temporal patterns were observed for conventional parameters, nutrients, major ions and total metals in the Near-field during open-water conditions. Temporal trends were not observed for field and laboratory pH, turbidity, total phosphorus, dissolved phosphorus, nitrate, nitrite, total ammonia, fluoride, sulphate, total antimony, boron, cobalt, iron, lead, manganese, selenium, and uranium.

Temporal patterns detected during open-water conditions were as follows:

- Gradual increases in the Near-field area each consecutive year were observed for specific conductivity, hardness, total alkalinity, TDS, calcium, chloride, magnesium, potassium, sodium, total barium, and strontium in the Near-field. Similar temporal trends were observed in the Mid-field area. In the pooled reference area, similar temporal trends were observed for conductivity and total alkalinity.
- Step-trend increases in 2018 were observed in the Near-field area for total aluminum and lithium. Similar temporal trends were not observed in the Mid-field and reference areas.

- Step-trend increases in 2017 persisting to 2018 were observed for bicarbonate, TOC and DOC in the Near-field. Similar trends were observed in the Mid-field area for all three parameters, and in the reference areas for bicarbonate and TKN.
- Increasing temporal trends up to 2017 were observed for reactive silica, total arsenic, copper, mercury, molybdenum, and nickel. Similar temporal trends were observed in both the Mid-field and reference areas for these metals, and in the Mid-field area for reactive silica.

Increasing concentrations of TDS, hardness, DOC, TOC, TP and major ions may be related to ongoing construction activities on-site, sewage effluent, and/or mine effluent discharge. Increases in total aluminum and lithium in 2018 in the Near-field area only (i.e., no observable temporal trend in the Mid-field or reference areas) suggest that these metals may have increased as result of mine effluent discharge from the CP1 diffuser; concentrations of both metals are still relatively low in the Near-field area (i.e., median concentrations during open-water in 2018 were 8.3 and 1.5 µg/L for total aluminum and lithium, respectively). However, there is uncertainty associated with identifying a source of water quality temporal trends in the Near-field area due to the limited dataset. Temporal trends will continue to be monitored in future AEMP programs to identify potential Mine-related effects on water quality in Meliadine Lake.

Despite temporal trends observed for several parameters in the Near-field area during open-water conditions between 2015 and 2018, all concentrations were well below applicable water quality guidelines in 2018 (Section 6.4.2.1.2) and therefore, are below levels expected to result in adverse effects on aquatic life.

6.4.6 Comparisons to FEIS predictions

As per FEIS predictions, water quality guidelines for the protection of aquatic and human health (CCME 1999; Health Canada 2017) were expected to be met at the edge of the mixing zone (i.e., in the Near-field area) and no residual impacts from the effluent discharge were anticipated in Meliadine Lake outside of the mixing zone (i.e., same as baseline conditions; and below WQGs). Minor changes in water quality in Meliadine Lake were predicted at the edge of the mixing zone. A minor change is a measurable increase in a water quality parameter that is outside the range of baseline values but is still within water quality guidelines.

In the mixing zone, FEIS predictions indicated that DO could fall below the CWQG-PAL (i.e., 6.5 mg/L) in late summer during the operations phase. In 2018, concentrations of DO in Meliadine Lake in all areas were above the CCME CWQG-PAL during ice-covered and open-water conditions.

Median concentrations in the Near-field area during open-water conditions were compared to maximum allowable effluent concentrations predicted at the edge of the mixing zone (Appendix 7.4A in Agnico Eagle 2014; Table 6.4-7). The 2018 water quality in Near-field area was within FEIS predictions, with the following exception: chloride concentrations during open-water (13 mg/L) and ice-covered (15 mg/L) conditions were just below and above (respectively) the FEIS prediction of 14 mg/L at the edge of the mixing zone. Fluoride and sodium concentrations were just above FEIS predictions, but major ion concentrations were below their respective WQGs (Section 6.4.2.1.2). Median TDS concentrations under-ice were at the FEIS prediction of 68 mg/L, whereas during open-water conditions TDS concentrations were just below the FEIS prediction at 53 mg/L. All other parameter concentrations fell below FEIS predictions at the edge of the mixing zone.

The preliminary maximum allowable effluent concentrations in the mixing zone represent a snap-shot of predicted effects during mine effluent discharge. FEIS predictions were modelled for TDS, chloride, and sodium and assumed that accumulation would occur in the east basin of Meliadine Lake (based on the characteristics of the basin). It was predicted that concentrations of these parameters would gradually increase during the construction

and operation phases of the Mine and that maximum concentrations would be achieved in the final year of operations (i.e., 176, 66, and 19 mg/L for TDS, chloride, and sodium, respectively). Concentrations of major ions in the Near-field area have increased over time (Section 6.4.5), but median open-water concentrations (i.e., 53, 13, and 5.7 mg/L for TDS, chloride, and sodium, respectively) are still well below predicted maximum concentrations in the final year of operations.

Concentrations of several parameters have increased over time in the Near-field area during ice-covered and open-water conditions (Section 6.4.2.1.2; Section 6.4.5), and were outside the normal range in recent years (Section 6.4.3):

- Field specific conductivity, hardness, turbidity, TDS, and major ions have gradually increased in the Near-field area over time, and compared to the Mid-field and reference areas. In 2018, these parameters (with the exception of turbidity and selected major ions) were outside their respective normal ranges for Meliadine Lake in the Near-field and Mid-field areas.
- TOC and DOC have increased in the Near-field area relative to the Mid-field and reference areas, and TOC concentrations have increased in 2018 relative to previous AEMP monitoring years. In 2018, TOC and DOC were outside of their respective normal ranges for Meliadine Lake in the Near-field area but not in the Mid-field area.
- Increasing temporal trends up to 2017 were observed for total copper, mercury, molybdenum, nickel, and uranium. Similar temporal trends were observed in both the Mid-field and reference areas for these metals. These metals were outside their respective normal ranges in the Near-field and Mid-field in 2018 for mercury and nickel.
- Increasing temporal trends up to and including 2018 were detected for total aluminum, barium, lithium, and strontium. Total barium and strontium have increased in each consecutive year. During open-water conditions, total aluminum and lithium increased in the Near-field area relative to the Mid-field and reference areas, and relative to previous AEMP monitoring years. In 2018, these parameters were outside their respective normal ranges in the Near-field area for all parameters, and in the Mid-field area for barium and strontium.

Increases in specific conductivity and concentrations of major ions, organics and selected total metals in the Near-field area over time, combined with spatial patterns observed in 2018, suggest a Mine-related effect on water quality. Concentrations of TDS, and major ions in Meliadine Lake were projected to increase during all phases of Mine operation. Lake-wide mean/median concentrations for all water quality parameters in Meliadine Lake during ice-covered and open-water conditions were within expectations and remained below WQGs.

Table 6.4-7: Water Quality in the Near-field Area in Meliadine Lake in 2018 Compared to FEIS Predictions for the Edge of the Mixing Zone

Parameter	Unit	FEIS Predictions at Edge of Mixing Zone	2018 Median Values

6.5 Summary

6.5.1 EEM

The results of the EEM water quality monitoring program are summarized below:

- In 2018, surface water quality monitoring for the Meliadine Mine was performed on two occasions as part of the EEM program: 19 to 25 July, and 15 August to 2 September.
- Concentrations of water quality parameters in the exposure area (Near-field area) and reference area (Reference Area 1) were below the CWQG-PAL.
- Nitrate, nitrate and nitrite, total aluminum, arsenic, lithium, magnesium, and titanium, as well as dissolved aluminum, arsenic, cobalt and lithium were two times higher in the exposure area, relative to the reference area.

6.5.2 AEMP

This section summarizes the water quality results relative to guidelines, normal ranges and FEIS predictions in the context of the two key questions for the AEMP water quality component.

Are concentrations of key parameters in Meliadine Lake consistent with FEIS predictions and less than AEMP Action Levels?

In 2018, concentrations and values of water quality parameters in Meliadine Lake remained within their respective WQGs during ice-covered and open-water conditions. Concentrations and values of key water quality parameters in all areas of Meliadine Lake were measured within CWQG-PAL and CDWQG.

Water quality in the Near-field and Mid-field areas of Meliadine Lake in 2018 was outside of the normal range for specific conductivity, TDS, hardness, several major ions and selected total metals (Section 6.4.3). However, the water quality in the Near-field area was generally consistent with FEIS predictions (Section 6.4.6).

An assessment of water quality parameters and exceedances of Action Levels is provided in Section 12.2.2.

Are concentrations in the exposure area increasing over time relative to the reference areas?

Increasing concentrations over time in the Near-field area and relative to temporal variation in reference areas were identified for specific conductivity, hardness, TDS, major ions (in particular calcium, chloride, magnesium, potassium, sodium, and sulphate), TOC, DOC, total aluminum, barium, lithium, and strontium. Concentrations of these parameters also exceeded the upper bound of their respective normal ranges in the Near-field area. Concentrations declined with distance from the Near-field area, but exceeded the upper bound of their respective normal ranges in the Mid-field area for all parameters except calcium, TOC, DOC, aluminum, and lithium. All parameters were within their respective normal ranges in the reference areas.

The analysis of the 2018 water quality results focused on comparing 2018 and 2017 construction phase data to pre-construction phase data in the Near-field area, and comparing water quality between the Near-field, Mid-field and reference areas in 2018. The observed changes in water quality suggest a Mine-related effect on water quality in the Near-field and Mid-field areas. The effect is within the range of conditions predicted by FEIS. However, given the limited dataset, there is uncertainty associated with identifying a source for the spatial and temporal trends identified in this report. It is anticipated that the 2019 and 2020 monitoring will allow for more detailed analysis of trends and Mine-related effects.

6.6 Recommendations

There are no recommendations for the 2019 AEMP water quality monitoring program.

6.7 List of Appendices

- Appendix 6A Water Quality QA/QC, which includes detailed methods and findings from the QA/QC assessment for the 2018 AEMP water quality program;
- Appendix 6B Normal Range Data Screening, which includes detailed description of the data screening approach and results used for calculating the normal ranges for water quality in Meliadine Lake;
- Appendix 6C Field Water Profile Measurements, which includes field data tables and vertical field profile plots;
- Appendix 6D 2018 Water Chemistry Tables, which includes raw water chemistry data tables for the 2018 water quality monitoring program in Meliadine Lake;
- Appendix 6E Statistical Outliers, which includes a data tables of statistical outliers excluded from spatial and temporal statistical analysis in the 2018 AEMP water quality monitoring report for Meliadine Lake;
- Appendix 6F Time-series Plots, which includes time-series plots of AEMP data collected in the Near-field, Mid-field and reference areas between 2015 and 2018 during open-water and ice-covered conditions;
- Appendix 6G Temporal Box-and-Whisker Plots by Area, which includes box-and-whisker plots for select parameters in the Near-field, Mid-field and reference areas between 2015 and 2018 during open-water and ice-covered conditions; and,
- Appendix 6H Historical Summary Statistics for the Near-field, which includes summary statistic tables for Near-field data collected in Meliadine Lake between 2015 and 2017.

7.0 WATER QUALITY – PENINSULA LAKES

In support of the AEMP and Water Licence (2AM-MEL1631) requirements of the Mine, water quality monitoring was completed between 2015 to 2018 in Peninsula Lakes.

This report section provides a summary of the water quality monitoring programs completed in 2018 at Peninsula Lakes, and an interpretation of the results as per the requirements of the AEMP. Data analyses presented in this report were based on the AEMP Design Plan (Golder 2016a), and response to comments from ECCC, INAC, and KIA during review of the 2017 AEMP Annual Report (Golder 2018a).

7.1 Objectives

The specific objective of AEMP monitoring activities at Peninsula Lakes was to detect potential indirect effects of the Mine on the lakes (i.e., aerial deposition and physical alteration of watersheds). The primary objectives of the water quality component of the Peninsula Lake study, as defined in the AEMP Design Plan (Golder 2016a) were to:

- characterize and interpret water quality in the selected monitoring lakes for purposes of identifying Mine-related effects;
- verify and update the FEIS predictions;
- assess efficacy of impact mitigation strategies to minimize the water quality effects of the Mine; and,
- provide data to inform management intended to reduce or eliminate Mine-related effects to water quality in the Peninsula Lakes.

To meet the primary objectives of the water quality component, analysis and interpretation of water quality data in 2018 were focused on answering two key questions, as defined in the AEMP Design Plan (Golder 2016a):

1) Are concentrations of key parameters in the Peninsula Lakes consistent with FEIS predictions and less than AEMP benchmarks[2]?

2) Are concentrations in the Peninsula Lakes increasing over time relative to baseline or reference conditions?

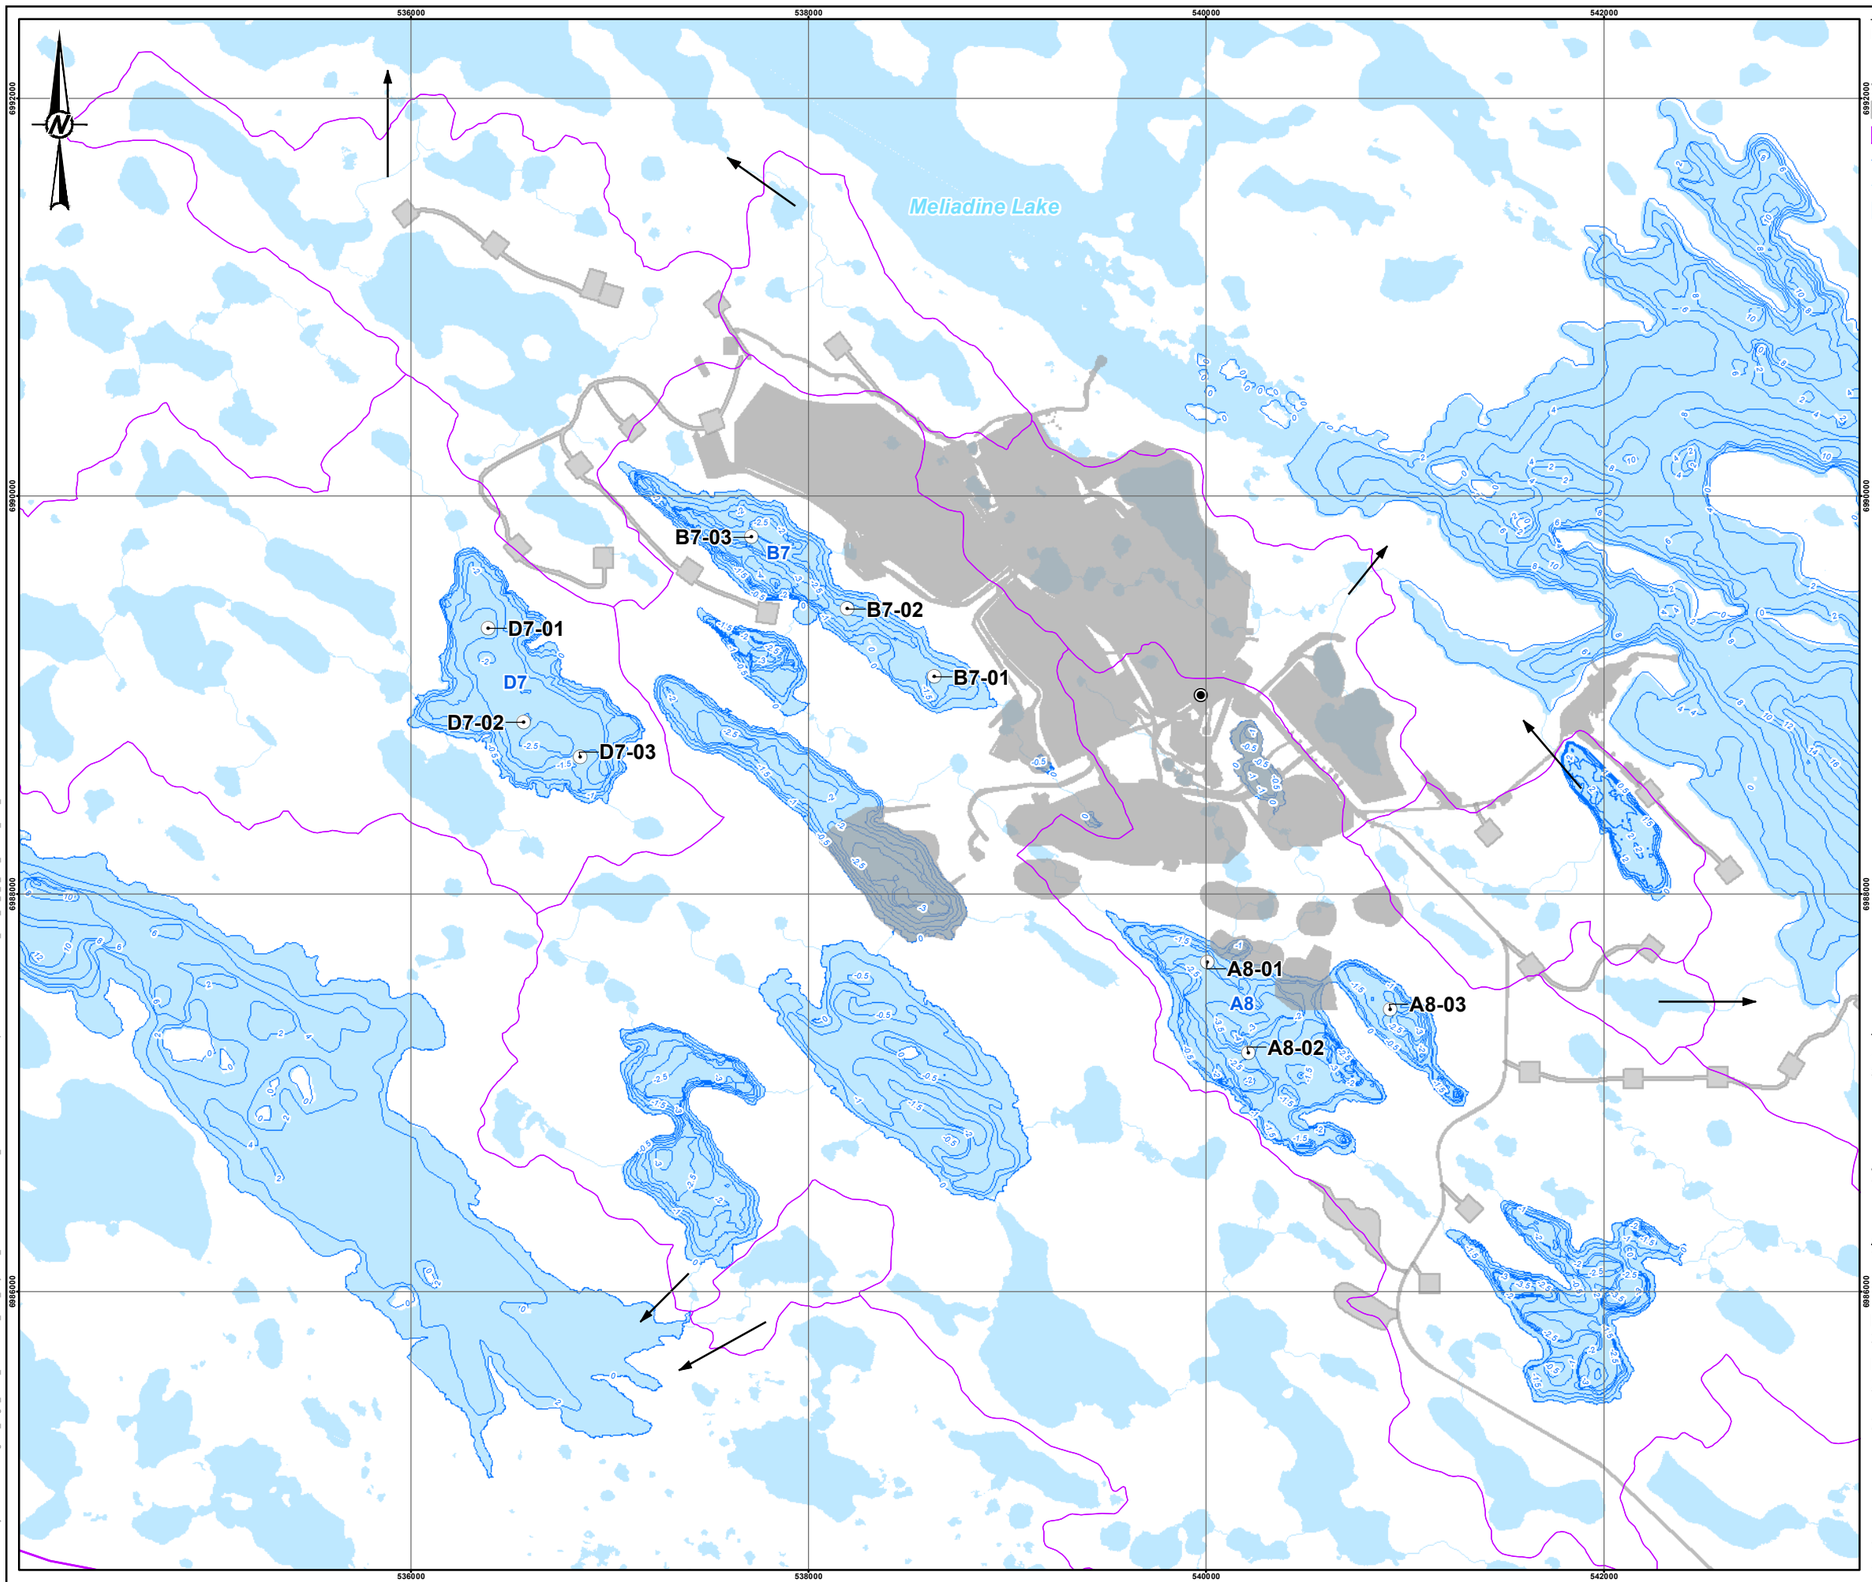
For the field survey and data analysis methods used to answer the key questions are described in Section 7.2. A summary of QA/QC assessment on the 2018 data are provided in Section 7.3. Results and discussion are presented in Section 7.4. and a summary of the water quality results and conclusions is provided in Section 7.5.

[2] This key question has been revised to refer to AEMP benchmarks instead of Action Levels.

7.2 Methods

7.2.1 Sampling Design

The 2018 Peninsula Lakes program consisted of two sampling programs during open-water conditions (Table 6.2-1). As a result of a number of site-related factors of field-related occurrences, a few adjustments were made to each program. These included the following:



- Field pH measurements collected at stations B-07-01 and B-07-02 during the July program and A8-01, A8-02, A8-03, B7-01, B7-02, and B7-03 during the August program were deemed unreliable during the data quality review (i.e., data were anomalous, being well outside the range of previously measured data; Appendix 6A), and were subsequently invalidated. These data were excluded from the assessments. For these invalidated field data, laboratory pH was used as a surrogate pH measurement to characterize open-water season water quality and in water quality guideline calculation at individual stations. However, as laboratory pH was measured outside the holding time requirement, it is acknowledged that these laboratory pH data have corresponding uncertainty.
- Stations D7-02 and D7-03 were not sampled as part of the July program because of weather delays (i.e., high wind).
- In 2018, water quality monitoring was scheduled for three times per calendar year, but the September water quality program was cancelled due to unsafe boating conditions (i.e., high winds) that prevented safe access to the open-water stations.

QA/QC procedures described in Section 7.3 and Appendix 6A were followed during the 2018 water quality monitoring program.

7.2.2 Field Methods

7.2.2.1 Sample Location and Sampling Frequency

As per the AEMP Design Plan, three stations in each of Lakes A8, B7, and D7, with a target water depth of 1.5 to 2.5 m, were sampled as part of the Peninsula Lakes study (Figure 7.2-1). The three lakes were sampled twice during the open-water season in July and August. The location and timing of sample collection in 2018 are summarized in Table 7.2-1.

Table 7.2-1: Water Quality Sampling Stations and Sampling Effort Summary for Peninsula Lakes in 2018

Peninsula Lake	Station ID	UTM Coordinates (NAD 83, Zone 15V)		Average Total Depth[a] (m)	Average Secchi Depth[b] (m)	22 to 24 Jul	17 Aug to 1 Sept
		Easting	Northing			Late Spring[c]	Summer[c]
Lake A8	A8-01	540007	6987659	2.3	-	✓	✓
	A8-02	540211	6987204	2.2	-	✓	✓
	A8-03	540925	6987421	1.7	-	✓	✓
Lake B7	B7-01	538631	6989096	1.0	-	✓	✓
	B7-02	538195	6989436	1.7	-	✓	✓
	B7-03	537713	6989798	1.7	-	✓	✓
Lake D7	D7-01	536390	6989340	1.7	-	✓	✓
	D7-02	536567	6988868	1.7	-	-[d]	Yes
	D7-03	536852	6988689	1.8	-	-[d]	Yes

Samples were analyzed for the required parameters listed in Table 6.2-2, except where noted otherwise.

✓ = Sample collected.

(a) The total depths recorded during each sampling program were averaged for individual stations, when stations were sampled on more than one occasion.

(b) The average Secchi depth (a measure of the clarity of surface waters) was not calculated because the secchi was visible to the lake bed at all stations.

(c) Blank samples (i.e., travel and equipment) were collected.

(d) Samples were not collected at these locations during the July program due to weather delays (i.e., high wind).

ID = identifier; UTM = Universal Transverse Mercator; NAD = North American Datum.

7.2.2.2 Collection of Supporting Field Measurements

At each sampling station, water depth and physicochemical measurements were collected. Total depth of the water column was measured either by using a sounding line or a boat-mounted sonar unit. Prior to collecting surface water samples, field measurements of the following four parameters were recorded using a Eureka Manta II multiprobe:

- water temperature (degrees Celsius [°C])
- pH
- DO (in mg/L and percent [%])
- specific conductivity (in microSiemens per centimetre [µS/cm])

In situ physicochemical measurements were taken at 0.5 m below the surface, and every 0.5 m thereafter throughout the water column, ending at approximately 0.5 m above the lake bed. Secchi depth was measured using a Secchi disk at each station.

7.2.2.3 Water Sample Collection

Surface water samples were collected as grab samples in accordance with Golder's technical procedures, the Standard Operating Procedures for Water Quality Sampling prepared by Golder, and specific laboratory instructions. Discrete water samples were collected at each sampling station from a depth of approximately 1 m using a Kemmerer sampler. Water for filling ultra-low metals and ultra-low mercury sample bottles were collected with a Teflon Kemmerer sampler, whereas the remaining bottles were filled with water from the Polyvinyl Chloride (PVC) Kemmerer sampler. At each station, the Kemmerer was triple-rinsed with surface water representative of the station, and then lowered to the required depth, triggered by the messenger to collect a sample, returned to the surface, and used to fill the lab-supplied sample bottles. This procedure was repeated until all sample bottles for the station were filled.

7.2.2.4 Laboratory Analysis

Water quality samples collected during the 2018 Peninsula Lake study were analyzed by ALS (Edmonton and Winnipeg locations). ALS is an analytical laboratory accredited by the CALA. Specific ALS analytical methods and RDL for the required analyses are provided in Appendix 6A.

Water sample bottles were provided by ALS (Section 7.2.2.3). Water samples were processed (i.e., filtered and/or preserved as required, and refrigerated) at site according to the instructions provided by the laboratory. Water samples requiring filtration were filtered through a 0.45 micrometre (µm) Millipore filter in a Nalgene filter tower using a vacuum pump before being preserved with laboratory-provided preservative based on the required analysis. Water samples were kept refrigerated before shipping; ice packs were added to the coolers to keep the samples as cool as possible during transport. Samples were shipped to ALS as soon as possible after sample collection and processing.

Water quality samples were analyzed for the following suite of parameters:

- routine parameters: pH, specific conductivity, hardness, total alkalinity, total dissolved solids [TDS], total suspended solids [TSS], and turbidity
- major ions: bicarbonate, carbonate, chloride, fluoride, sulphate, calcium, magnesium, potassium, sodium, and silica
- nutrients: nitrate, nitrite, total ammonia, total Kjeldahl nitrogen [TKN], total nitrogen [TN], total phosphorus [TP], total dissolved phosphorus [TDP], orthophosphate, total organic carbon [TOC], and dissolved organic carbon [DOC]
- total and dissolved metals, metalloids, and non-metals[3]: aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, and zinc
- cyanide (i.e., weak acid dissociable, total, and free)

[3] Metals, metalloids (e.g., arsenic), and non-metals (e.g., selenium) are referred to as "metals" in this document.

The samples were analyzed using laboratory test methods with analytical DLs below the CWQG-PAL for the protection of aquatic life (CCME 1999), and Health Canada Drinking Water Quality Guidelines (CDWQGs; Health Canada 2017). Specific ALS analytical methods and RDL for the required analyses are provided in Appendix 6A.

7.2.3 Data Analysis

Comparisons of key parameters to FEIS predictions, water quality guidelines and normal ranges are provided in this section. Descriptive statistics were calculated and presented for the 2018 dataset by lake. Descriptive statistics included the sample size, mean, median, minimum, maximum, and standard deviation. Field data (physicochemical) profiles were compared graphically within each lake (by showing results for each station) to qualitatively evaluate vertical patterns. Water temperature, DO concentration and percent saturation, pH, and specific conductivity, were plotted against measured depth.

7.2.3.1 Comparison to Water Quality Guidelines

The approach for comparison to WQGs is outlined in Section 6.2.4.1. Guidelines and objectives are summarized in Table 6.2-2; these guidelines, in addition to baseline data, form a starting point for the future monitoring benchmarks.

Water quality results for Peninsula Lake stations were compared to acute and chronic CWQG-PAL (CCME 1999), drinking water quality guidelines and aesthetic objectives (Health Canada 2017). Water quality results from Peninsula Lake stations were also compared to the SSWQO developed for the Mine (Golder 2013).

Water chemistry results were plotted as a time series plot for each parameter at each station, with visual representation of guidelines and SSWQOs to qualitatively evaluate water quality trends against guidelines and SSWQOs in 2018, relative to previous years.

7.2.3.2 Normal Ranges

Normal range concentrations were calculated for Peninsula Lakes using water quality data collected during baseline conditions between 2015 and 2017, and using historical data collected between 1995 and 2011. The calculation methods used to estimate normal ranges are described in Section 6.2.4.2 and Appendix 6B.

7.2.3.3 Comparison to FEIS Predictions

Comparison of near-field exposure data for 2018 were compared to applicable model predictions reported by the FEIS for Meliadine (Agnico Eagle 2014). The FEIS predictions for water quality included an evaluation of the water quality in Lakes A8, B7, and D7 to evaluate the potential for indirect effects in small waterbodies within the vicinity of the Mine. The results of the model predictions indicated that changes to water quality in the small waterbodies could result from diversion of water, changes in watershed size and contributing areas, natural hydrological processes, evaporation, and aerial deposition of particulate matter (modelled as TSS), nutrients from blasting activities at the Mine (modelled as nitrate), and metals (modelled by individual metal parameter). It was predicted that aerial deposition from mine activities will increase from background levels during pre-production, peak during pit development, and decrease to background levels by closure (Agnico Eagle 2014). Specific model predictions for the small waterbodies were as follows:

- Total suspended solids (TSS) was not predicted to increase to concentrations that would affect aquatic life (i.e., concentrations will be less than guidelines, or less than 10% different from baseline conditions) in any waterbody.

- Nitrate was not predicted to increase to concentrations that would affect aquatic life (i.e., concentrations will be less than guidelines, or less than 10% different from baseline conditions) in any waterbody.
- In Lake A8, metal concentrations were not predicted to be more than background or guidelines.
- In Lake D7, titanium was expected to be more than 10% higher than background concentrations.

Lake B7 was not included in the model predictions under FEIS (Agnico Eagle 2014). These predictions are examined in Section 7.4.4.

7.2.3.4 Identification of Temporal Trends

Time series plots of parameter concentrations were completed (Appendix 7C) for stations in Peninsula Lakes A8, B7 and D7 and qualitatively examined to identify increasing trends in 2018 relative to baseline conditions (i.e., 2015 to 2017).

7.3 Quality Assurance/Quality Control

The QA/QC practices applied during this study and detailed results of the QC analyses for discrete water quality samples collected at Peninsula Lakes are provided in Appendix 6A. QA components of the program included the use of trained personnel and an accredited analytical laboratory; QC components included assessments of duplicates and field, equipment, and travel blank samples. Dissolved and total parameter concentrations were also compared.

7.3.1 Summary of Results

Detailed results are provided in Appendix 6A. The results of the review of field and laboratory data indicated that field measurements and laboratory data were of high quality. Key findings from the 2018 QA/QC evaluation are as follows:

- In general, field measurements and results of laboratory samples collected during the 2018 sampling program were within the ranges that would be expected for the Peninsula Lakes water quality program, with the exception of two field pH measurements collected in July and all field pH measurements collected in August at Lakes A8 and B7. These field pH measurements were invalidated because the values were far outside of the range of historical variation at these stations.
- No issues were identified in analytical methods used or units reported by the laboratory.
- Holding times recommended by the laboratory were for exceeded some parameters. The holding time exceedances were not expected to affect data quality for the Peninsula Lakes water quality program.
- QC samples were collected in coordination with the Meliadine Lake water quality program. QC samples (i.e., blanks and duplicates) accounted for approximately 16% of the total number of water samples submitted for analysis.
- The water quality QC sample evaluation indicated that for the combined equipment and travel blanks, 1% of parameters were detected at concentrations more than five times the DL. No notable contamination occurred in the blank samples.

- Approximately 3% of paired concentrations in duplicate discrete water quality samples had a RPD of more than 20%. Within-station variability and field precision for the 2018 dataset were rated as low and high, respectively.

The overall quality of the water quality data was rated high. Therefore, the results reported in the report are considered reliable and meet the needs of the program.

7.4 Results and Discussion

7.4.1 Field Measured PhysicoChemical Parameters

The field profiles generally followed similar patterns among Peninsula Lakes. A summary of field profiles for Lakes A8, B7, and D7 are presented in Appendix 7A, Tables 7A.1-1 to 7A.1-6, and below:

- No thermal stratification was observed during the July and August programs in the Peninsula Lakes (Appendix 7A, Figures 7A.1-1 and 7A.1-2). Average surface water temperatures were higher in July than August in all lakes. Average temperatures in Lake A8, B7, and D7 in July and August were 15.7°C and 11.7°C, 17.1°C and 10.5°C, and 18.0°C and 9.7°C, respectively.
- DO was close to saturated in all lakes in July and August, and remained relatively constant through the water column (Appendix 7A, Figure 7A.1-3 and 7A.1-4). Surface DO was well above CWQG-PAL of 6.5 mg/L at all stations in the Near-field and Mid-field.
- Water column pH in Lake A8, B7, and D7 ranged between 8.3 to 8.6 in all lakes and was consistent with depth in July and August (Appendix 6C, Figure 6A.1-5 and 6A.1-6). Surface pH was within the acceptable CWQG-PAL range of 6.5 to 9.0 at all stations during the open-water season.
- Water column specific conductivity was constant with depth in all lakes in July and August (Appendix 7A, Figure 7A.1-7 and 7A.1-8). Water column specific conductivity was highest in Lake A8 ranging between 193 to 240 µS/cm compared to 134 to 159 µS/cm in Lake B7 and 117 to 141 µS/cm in Lake D7.

7.4.2 Water Chemistry

Water quality results from 2018 in the Peninsula Lakes are presented below and summarized in Table 7.4-1. Raw water quality data collected between 2015 and 2018 are provided in Appendix 7B, Table 6B-1 to 6B-6. Peninsula Lakes water quality can be characterized as having:

- low to moderate ionic strength (median laboratory specific conductivity in Lake A8, B7 and D7 was 225, 151, and 142 µS/cm, respectively);
- bicarbonate, chloride, and calcium as the major ions; chloride, fluoride, sodium, and sulphate concentrations fell below their applicable WQGs in Peninsula Lakes;
- basic pH (median field-measured pH across all lakes ranged from 7.6 to 7.8). Field and laboratory pH were within the acceptable range (i.e., 6.5 to 9.0) of the CWQG-PAL for all samples in Lakes A8, B7, and D7;
- low to moderately low hardness (hardness was low in Lakes B7 and D7 with median values of 57 and 48 mg/L as $CaCO_3$, respectively and moderately low in Lake A8 with a median value of 84 mg/L; this indicates soft water in Lake B7 and D7 and moderately soft water in Lake A8, according to the scale of water hardness by McNeely et al. [1979]);

- low to moderate TDS with median concentrations of 174, 101, and 77 mg/L in Lakes A8, B7, and D7, respectively. TDS concentrations fell below the aesthetic objective of 500 mg/L.
- low nutrient concentrations, with median TP and TN concentrations in Lakes A8, B7 and D7 of 0.0047 and 0.40 mg/L, 0.0069 and 0.37 mg/L, and 0.016 and 0.35 mg/L, respectively. The concentrations of TP and TN in the Peninsula Lakes were within the range of oligotrophic lakes classification, according to the scale of trophic status by Vollenweider (1968). Nitrate, nitrite, and total ammonia concentrations fell below their applicable WQGs in Peninsula Lakes; and
- low total and dissolved metal concentrations in all lakes, which were either below detection or below water quality guidelines.

Table 7.4-1: Water Quality Summary at Peninsula Lakes, 2018

(a) Temperature for some samples fell above the aesthetic objective of 15°C but were not flagged in this table.

(b) The ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.6) and water temperature (15.6°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. When field pH was not available laboratory pH was used.

(c) Guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.8 to 8.9). The guideline is calculated based on the individual pH for each sample. When field pH was not available laboratory pH was used.

(d) Guideline is pH dependent: 5 µg/L at pH <6.5 and 100 µg/L at pH ≥ 6.5. When field pH was not available laboratory pH was used.

(e) Guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43.6 to 86.2 mg/L as $CaCO_3$). The guideline is calculated based on the individual hardness value for each sample.

(f) Guideline is for chromium VI.

(g) Guideline is hardness and DOC dependent. The guideline range shown is based on the hardness (43.6 to 86.2 mg/L as $CaCO_3$) and DOC (3.2 to 4.7 mg/L) range observed in the dataset. The guideline is calculated based on the individual hardness and DOC for each sample. All guidelines fell within the validated range for hardness (13.8 to 250.5 mg/L as $CaCO_3$) and DOC (0.3 to 17.3 mg/L).

(h) Guideline is pH, hardness and DOC dependent. The guideline range shown is based on the of field pH (7.8 to 8.9), hardness (43.6 to 86.2 mg/L as $CaCO_3$) and DOC (3.2 to 4.7 mg/L). The guideline is calculated based on the individual hardness and DOC for each sample. All guidelines fell within the validated range for pH (6.5 to 8.13), hardness (23.4 to 399 mg/L as $CaCO_3$) and DOC (0.3 to 22.9 mg/L). When field pH was not available laboratory pH was used.

Note:

In cases where 50% or more of data were <DL, no mean or standard deviation was calculated.

Half of the detection limit value was used for total Kjeldahl nitrogen to calculate total nitrogen concentrations.

No concentrations were higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision after comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

CCME = Canadian Council of Ministers of the Environment; SSWQO = site-specific water quality objective; SD = standard deviation; µS/cm = microSiemens per centimetre; NTU = nephelometric turbidity unit; mg/L = milligrams per litre; mg-P/L = milligrams phosphorus per litre; mg-N/L = milligrams nitrogen per litre; µg/L = micrograms per litre; DOC = dissolved organic carbon; $CaCO_3$ = calcium carbonate; WAD = Weak Acid Dissociable; - = no guideline or data not measured.

7.4.3 Comparison to Normal Range

The 2018 Lake A8 mean/median concentrations of total aluminum, arsenic, iron, and molybdenum were higher than upper bound concentrations of their respective normal ranges (Tables 7.4-2). The 2018 Lake B7 mean/median concentrations were higher than upper bound concentrations of their normal ranges for total boron, lithium, and strontium (Table 7.4-3). The 2018 Lake D7 mean/median concentrations of total ammonia, total barium, cobalt, manganese, molybdenum, nickel, and dissolved zinc were higher than upper bound concentrations of their normal ranges (Table 7.4-4).

Table 7.4-2: Normal Ranges (1997 to 2009; 2015 to 2017) for Selected Parameters, Lake A8

(a) Lake area means were calculated using the back-transformed mean when the normal range was defined as the prediction interval using Box-Cox transformed data. The arithmetic mean was used when the normal range was defined using untransformed data. The median was used when the calculation method was Percentile.

(b) Detection limit for laboratory pH is provided.

(c) Laboratory pH was used in place of field pH for select 2018 samples in cases where field pH was invalidated.

(d) The lower bound of the normal range was less than the detection limit; therefore, the lower bound of the normal range was set to zero.

(e) The upper bound of the normal range was less than the detection limit; therefore, the upper bound of the normal range was set to the detection limit.

(f) All values in the dataset were non-detect; therefore, the normal range was set from zero to the detection limit.

(g) Total nitrogen was not measured during the July or August 2018 water quality programs.

Bolded concentrations exceed the upper bound of the normal range.

Percentile = 2.5th and 97.5th percentiles; PI= 80% prediction intervals; PI(λ) = 80% prediction interval on Box-Cox transformed data.

mg/L = milligrams per litre; µS/cm = microSiemens per centimetre; NTU = nephelometric turbidity unit; mg‑N/L = milligrams nitrogen per litre; mg‑P/L = milligrams phosphorus per litre; µg/L = micrograms per litre.

(a) Lake area means were calculated using the back-transformed mean when the normal range was defined as the prediction interval using Box-Cox transformed data. The arithmetic mean was used when the normal range was defined using untransformed data. The median was used when the calculation method was Percentile.

(b) Detection limit for laboratory pH is provided.

(c) The lower bound of the normal range was less than the detection limit; therefore, the lower bound of the normal range was set to zero.

(d) The upper bound of the normal range was less than the detection limit; therefore, the upper bound of the normal range was set to the detection limit.

(e) All values in the dataset were non-detect; therefore, the normal range was set from zero to the detection limit.

Bolded concentrations exceed the upper bound of the normal range.

Percentile = 2.5th and 97.5th percentiles; PI= 80% prediction intervals; PI(λ) = 80% prediction interval on Box-Cox transformed data.

mg/L = milligrams per litre; µS/cm = microSiemens per centimetre; NTU = nephelometric turbidity unit; mg‑N/L = milligrams nitrogen per litre; mg‑P/L = milligrams phosphorus per litre; µg/L = micrograms per litre; - = normal range could not be calculated because all values in the dataset were below detection.

7.4.4 Comparison to FEIS Predictions

As per FEIS predictions, it was expected that WQGs would be met for all parameters in Peninsula Lakes and that minor changes to water quality would occur as a result of indirect effects from Mine-related activities. (Agnico Eagle 2014). The 2018 water quality data were examined relative to the specific model predictions for the Peninsula Lakes.

- Mean/median concentrations for all water quality parameters in remained below their respective WQGs;
- Concentrations of TSS measured in 2018 in the Peninsula Lakes were within the normal range;
- Concentrations of nitrate measured in 2018 in the Peninsula Lakes were within the normal range;
- In Lake A8, concentrations of four metals exceeded the upper bound of the respective normal range: total aluminum, arsenic, iron, and molybdenum. However, these metals did not exceed the upper bounds of their respective normal range by more than 10%, with the exception of iron.
- In Lake D7, titanium concentrations were within the normal range.

7.4.5 Temporal Trends

Water quality data within each Peninsula Lake were qualitatively examined for temporal patterns on time-series plots presented in Appendix 7C. Temporal patterns were observed for some parameters in Lake A8, B7, and D7 as follows:

- Steady increases in concentrations in each consecutive year were observed for: reactive silica, total aluminum and arsenic in Lake A8; dissolved phosphorus, and total aluminum in Lake B7; and dissolved phosphorus and total molybdenum in Lake D7.
- Step increase in concentration in 2018 (relative to previous years) was observed for: total manganese in Lake A8; total boron, lithium, strontium, and vanadium in Lake B7; total manganese and vanadium in Lake D7.

The analysis of the 2018 water quality results in the Peninsula Lakes focused on comparing year-to-year changes in water quality within each lake. It is anticipated that the 2019 and 2020 monitoring will allow for more detailed trends analysis and results interpretation with respect to potential Mine-related effects.

7.5 Summary

This section summarizes the water quality results relative to guidelines, normal ranges and FEIS predictions in the context of the two key questions for the AEMP water quality component.

Are concentrations of key parameters in Peninsula Lakes consistent with FEIS predictions and less than AEMP Action Levels?

In 2018, concentrations and values of water quality parameters in Peninsula Lakes remained below applicable WQGs and AEMP benchmarks for all parameters. Water quality in Peninsula Lakes in 2018 was outside of the normal range for some total metals in Lakes A8, B7, and D7 (Section 7.4.3). However, water quality in all lakes was generally consistent with FEIS predictions (Section 7.4.4).

Are concentrations in the Peninsula Lakes increasing over time relative to baseline or reference conditions?

A qualitative analysis of temporal trends observed increasing trends in each consecutive year for reactive silica (Lake A8), dissolved phosphorus (Lake B7 and D7), total aluminum (Lake A8 and B7), arsenic (Lake A8), and molybdenum (Lake D7), relative to previous AEMP monitoring years. A step-increase in concentrations in 2018 (relative to previous monitoring years) was observed for total manganese (Lake A8 and D7), total boron, lithium, and strontium (Lake B7), and total vanadium (Lake B7 and D7). The analysis of the 2018 water quality results focused on visually comparing 2018 construction phase data to pre-construction phase data in the Peninsula Lakes and detecting gradual trends. Given the limited dataset, there is uncertainty associated with trend detection, and potential sources of the temporal trends are not identified in this report. It is anticipated that the 2019 and 2020 monitoring will allow for more detailed trend analysis.

7.6 Recommendations

There are no recommendations for the 2019 Peninsula Lake water quality program.

7.7 List of Appendices

- Appendix 7A Field Plots, which includes field data tables and vertical field profile plots;
- Appendix 7B 2018 Water Chemistry Tables, which includes raw water chemistry data tables for the 2018 water quality monitoring program in the Peninsula Lakes; and,
- Appendix 7C Time-series plots, which includes time-series plots of AEMP data collected in the Peninsula Lakes between 2015 and 2018.

8.0 SEDIMENT QUALITY

To date, sediment quality monitoring has been completed at Meliadine Lake in 2015, 2016, and 2018 to meet Type A Water Licence requirements, and to meet MDMER EEM program requirements for the first year of the mine effluent discharge in 2018. Sampling was completed in August as per the AEMP Design Plan and the Cycle 1 EEM Study Design approved by the relevant regulatory agencies (Golder 2016, 2017).
Sediment monitoring programs in 2015 and 2016 were intended to characterize baseline conditions within exposure and reference areas on Meliadine Lake. Sediment quality and supporting data generated were evaluated in the 2017 AEMP Annual Report to establish baseline conditions for the AEMP prior to the onset of operations (Golder 2018c).

This section provides a summary of sediment quality data obtained in 2018 during the first year of mine effluent discharge, an analysis of the baseline and construction data collected between 2015 and 2018 in Meliadine Lake, and an interpretation of the results as per the requirements of the AEMP and EEM programs.

Data analyses presented in this section have been undertaken as per the AEMP Design Plan (Golder 2016a), the Cycle 1 EEM Study Design (Golder 2017a), and in response to comments from ECCC, INAC, and KIA during review of the 2017 AEMP Annual Report. The report also considers comments provided by ECCC on that design document (Golder 2018d).

8.1 Objectives

According to the AEMP Design Plan (Golder 2016a), the objective of the sediment quality component is to determine whether treated Mine effluent has had effects on sediment quality in Meliadine Lake, and to provide supporting information for the AEMP benthic invertebrate component. Specific objectives of the sediment quality component were to:

- characterize sediment quality in Meliadine Lake;
- verify predictions made in the FEIS in relation to sediment quality in Meliadine Lake (Agnico Eagle 2014);
- collect supporting data for the benthic invertebrate and water quality components to aid in interpretation of results (as per Part 2, Schedule 16 (a) (iii) of the MDMER regulations [Government of Canada 2018]); and
- provide data to inform adaptive management intended to reduce or eliminate Mine-related effects on Meliadine Lake sediment quality.

To achieve these objectives, analysis and interpretation of sediment quality data in 2018 were focused on answering two key questions, as defined in the AEMP Design Plan (Golder 2016a):

- Are concentrations of sediment quality parameters in Meliadine Lake less than benchmarks?
- Are concentrations in the exposure area increasing over time relative to the reference areas?

Field survey and data analysis methods employed to answer these key questions are described in Section 8.2. A summary of quality assurance (QA) and quality control (QC) assessment on the 2018 data is provided in Section 8.3. Results and discussion are presented in Section 8.4. Results to meet AEMP requirements are discussed in this section, followed by results to meet the Cycle 1 EEM study requirements not already covered under the AEMP. A summary of the sediment quality results and conclusions are provided for both the AEMP and the Cycle 1 EEM study in Section 8.5.

8.2 Methods

8.2.1 Sampling Design

The 2018 sediment quality program was designed to align with the AEMP Design Plan (Golder 2016a) and Cycle 1 EEM requirements under the MDMER (Golder 2017a, 2018b; Government of Canada 2018). The program consisted of one sediment sampling event with concomitant water quality and benthic invertebrate sampling events in August 2018.

As previously described in the 2017 AEMP Annual Report (Golder 2018c), the Near-field and reference areas had different substrates, with the Near-field area being silt-dominated and the reference areas sand-dominated. In order to minimize this potential confounding factor, a Sediment Reconnaissance Survey (Appendix 9A) was planned and executed in July 2018 prior to the sediment quality sampling event. The purpose of the survey was to further investigate suitable and comparable stations for sediment and benthos sampling within the already established exposure and reference areas. Based on the survey results and consideration of the Plume Delineation Study (Section 2.2.4), some sampling stations were relocated for the August 2018 sampling event to optimize the AEMP and EEM sampling locations. Detailed results of the Sediment Reconnaissance Survey are presented in Appendix 9A.

Although the 2018 study design remained consistent with the AEMP Design Plan and the Cycle 1 EEM Study Design, there were some modifications to sampling station locations as a result of the Sediment Reconnaissance Survey and the Plume Delineation Study (Section 2.4.4). Specific deviations in relation to station location were as follows:

- **Near-field Stations**: MEL-01-01 was retained because it was the only original station included by the water quality component Near-field station re-alignment after review of the 2018 plume delineation study results (Section 2.4.3). Furthermore, the 2018 Sediment Reconnaissance Survey confirmed that sampling efficiency and grab fullness at this station were acceptable. The other four stations confirmed by the water quality station re-alignment (i.e., MEL01-06, MEL01-07, MEL01-08 and MEL01-09) were also adopted as 2018 sediment and benthic monitoring stations because they had acceptable sampling efficiency and grab fullness. Furthermore, substrate composition was relatively consistent among the five 2018 Near-field water quality stations.
- **Mid-field Stations**: 2018 sediment stations were selected to maintain alignment with water quality, and also to avoid excessive sampling effort in retrieving acceptable grab samples. Therefore, MEL-02-06 and MEL-02-08 were chosen to replace MEL-02-01 and MEL-02-04, because of difficulty retrieving acceptable samples from MEL-02-01 and MEL-02-04 with respect to sample fullness and efficiency. For stations that were re-sampled for consistency with previous years, some stations were adjusted to within 5 to 10 m of the original sample locations.
- **Reference Areas**: Sediment quality samples were not taken from the MEL-04 reference area (Reference Area 2) due to meteorological challenges; i.e., strong winds during August that limited the time available for sediment sampling, such that only two of the three reference areas were sampled. Reference Area 2 was removed from the sampling program, because of limited similarity in terms of sample composition to the Near-field area during previous sampling years (i.e., 2015 and 2018), and limited sampling success during the Sediment Reconnaissance Survey (Appendix 9A). Reference areas 1 (MEL-03) and 3 (MEL-05) were sampled in 2018.

QA/QC procedures described in Section 8.3 were followed during the 2018 sediment quality monitoring program.

8.2.2 Field Methods

8.2.2.1 Sample Location and Timing

According to the AEMP Design Plan, five stations in each one of the five sampling areas were scheduled to be sampled once during the open-water season, in August 2018. EEM and AEMP sampling areas were aligned, in that the Near-field area was considered the EEM exposure area and Reference Area 1 was considered the EEM reference area. The location and timing of sample collection is summarized in Table 8.2-1 and presented in Figure 8.2-1.

8.2.2.2 Sediment Sample Collection

The sediment quality monitoring program was based on the AEMP Design Plan (Golder 2016a), the Cycle 1 EEM Study Design (Golder 2017a), and the EEM TGD for metal mines (Environment Canada 2012) (hereafter referred to as TGD). Sediment quality samples were collected as a composite of grab samples from surficial sediments at each station. Sediment samples were collected either on the same day or within two days before or after collection of water quality samples. When water and sediment samples were collected on the same day, sediment samples were collected after all *in situ* measurements and water quality samples had been collected.

Composite sediment samples were collected using a stainless steel Petite Ponar grab (15.24 × 15.24 cm; bottom sampling area of 0.0232 m²). Each composite sample comprised up to five separate grabs collected at the sampling station. Lake sediment was removed from the Ponar grab with a plastic trowel; sediments were removed from the center of the grab to avoid the metal sides of the Ponar grab, from the upper 5 cm of the sample. The process was repeated up to five times until sufficient sediment was collected (approximately 450 g dry weight or 1.5 kg wet weight) for analysis of the required parameters. Sediment samples were composited by placing each of the five subsamples into a clean, shallow, plastic pan and mixed with a plastic spoon. Sediment samples were placed in plastic bags and jars provided by the analysical laboratory, kept refrigerated, and transported to the laboratory as soon as possible.

8.2.3 Laboratory Methods

Sediment quality samples were analyzed by ALS (Edmonton and Saskatoon). ALS is an analytical laboratory accredited by the CALA. Specific ALS analytical methods and RDL for the required analyses are provided in Appendix 8A.

Sediment samples were then analyzed for the following parameters:

- particle-size distribution (sand: 0.05 to 2 mm; silt: 0.002 to 0.05 mm; and clay: <0.002 mm);
- total organic carbon; and
- metals: aluminum, antimony, arsenic, barium, beryllium, bismuth, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, sulfur, thallium, tin, titanium, uranium, vanadium, and zinc.

Sediment quality laboratory test methods with analytical DLs less than the CCME sediment quality guidelines for the protection of aquatic life (CCME 2001) were used to analyze the samples collected in 2018.

8.2.4 Data Analysis

The data analysis approach for the 2018 sediment quality data was developed to address Cycle 1 EEM Study Design and AEMP Design Plan requirements (Golder 2016, 2017). These included calculation of descriptive statistics, comparison of sediment chemistry to available CCME guidelines, statistical comparisons between exposure areas and reference areas, temporal comparison between years for the Near-field area, a comparison to FEIS predictions, and comparison to normal ranges calculated for the AEMP.

Details of data analysis methods are provided in the following subsections.

8.2.4.1 Summary Statistics and Comparison to Canadian Sediment Quality Guidelines

Comparisons to sediment quality guidelines allow an assessment of potential adverse effects to aquatic biota. CCME sediment quality guidelines are based on toxicological information according to a standard protocols (CCME 2001). These guidelines apply Canada-wide and do not necessarily account for site-specific factors, such as the natural geology of the study area. Thus, guideline exceedances in reference areas can be indicative of naturally elevated concentrations due to site-specific factors. Sediment quality can vary spatially within a lake or between lakes due to lake morphology, composition of the bedrock, interaction of surface and groundwater, tributary inputs, and other factors.

Descriptive statistics were calculated from data collected from the exposure and reference areas sampled in 2018. Specifically, mean, median, minimum, maximum values were calculated and compared to CCME Interim Sediment Quality Guideline (ISQG) and Probable Effects Level (PEL) for the protection of freshwater aquatic life (CCME 2001; Table 8.2-2). The percentage of exceedances above sediment quality guidelines was also calculated, and sample size and standard deviation were provided. For mean and standard deviation calculations, data below the RDL were replaced with half the RDL. When more than 50% of the data were below RDL, the standard deviation was not calculated.

CCME (2001) indicates that at concentrations below the ISQG, adverse biological effects are not expected to occur, while at concentrations above the ISQG adverse biological effects may occur. At concentrations above the PEL adverse biological effects are likely, but not certain, to occur.

Table 8.2-2: Canadian Sediment Quality Guidelines for Metals

Parameter	Unit	Canadian Council of Ministers of the Environment Sediment Quality Guidelines[a]	
		Interim Sediment Quality Guideline (ISQG)	Probable Effect Level (PEL)
Arsenic	µg/g dw	5.9	17
Cadmium	µg/g dw	0.6	3.5
Chromium	µg/g dw	37.3	90
Copper	µg/g dw	35.7	197
Lead	µg/g dw	35	91.3
Mercury	µg/g dw	0.17	0.486
Zinc	µg/g dw	123	315

(a) CCME (2001).

µg/g dw = micrograms per gram dry weight.

8.2.4.2 Statistical Analysis

8.2.4.2.1 Exposure versus Reference: 2018 Spatial Comparison

8.2.4.2.1.1 EEM

Given that sediment quality is a supporting component within the EEM program, the TGD does not provide specific details on comparisons of sediment quality between exposure and reference areas. The TGD recommends that particle-size and TOC analysis be used to determine if there are habitat differences between exposure and reference areas. The TGD encourages the determination of metal concentrations in sediments to facilitate interpretation of BIC data collected concurrently. Thus, to address EEM requirements for this report and as communicated in the approved Cycle 1 EEM Study Design, particle-size distribution, TOC and metal concentrations were summarized statistically, screened against applicable sediment quality guidelines, and qualitatively compared between the EEM exposure and reference areas. The findings of this assessment support the comparison of benthic invertebrate communities among sampling areas in Section 9.4.1.

8.2.4.2.1.2 AEMP

Spatial patterns in 2018 were qualitatively and statistically examined to determine if sediment quality differed among Near-field and Mid-field exposure areas, and reference areas. Box-and-whisker plots of sediment chemistry parameters from Near-field and Mid-field exposure areas and pooled reference areas were visually evaluated for spatial patterns. Additionally, a statistical analysis was undertaken to determine if there were significant differences in parameter concentrations between Near-field exposure, Mid-field exposure, and the reference areas.

Prior to statistical analyses, values below the RDL were substituted with one-half of the RDL and normalized to percent fines. Statistical outliers were evaluated using SRs from the ANOVA model. A magnitude of |3.5| for the SR was used to identify observations that may be unusual. When an outlier was detected, the validity of the data point was examined. If the outlier was determined to be the result of a data entry error, it was corrected. If the outlier was not the result of data entry errors and could not be resolved otherwise, the analysis was completed with and without the outlier included.

To compare sediment quality parameter concentrations among AEMP areas in Meliadine Lake, an ANOVA was completed in SYSTAT Version 13.1 (Systat Inc. 2009), followed by *post-hoc* pairwise comparisons (Tukey's tests; Zar 1999) if the ANOVA test result was significant. Prior to analysis, the sediment quality data were checked for statistical assumptions (i.e., normality, and homoscedasticity; Zar 1999). If data did not meet the statistical assumptions, the equivalent non-parametric test (e.g., K-W with *post-hoc* Conover-Inman tests; Systat Inc. 2009) were completed. Data were considered significantly different at $\alpha = 0.1$.

Reference area data collected in 2018 were pooled and the following statistical comparisons were made:

- Near-field versus Mid-field area
- Near-field versus reference areas
- Mid-field versus reference areas

When significant differences in sediment quality parameters were observed between sampling areas, the magnitude of difference among the areas (i.e., Near-field, Mid-field and pooled reference) was calculated by expressing the difference as a percentage of the mean or median. The area farthest away from the Mine was set as the denominator in the calculation of magnitude of difference. For example, to calculate the magnitude of difference between Near-field and pooled reference areas for a parameter, the equation was as follows:

$$Magnitude = \frac{\bar{x}_{NF} - \bar{x}_{Reference\ Areas}}{\bar{x}_{Reference\ Areas}}$$

where $\bar{x}$ is the mean or median and NF is the Near-field area.

If the statistical comparison between sampling areas was conducted using the K-W test, the data were not considered to be normally distributed and the magnitude was calculated using medians. As the K-W test is a non-parametric method for testing whether samples originate from the same distribution (i.e., it is not a comparison of sample medians), situations were a K-W test was significant, but no differences in medians were observed are possible.

When spatial patterns were detected (i.e., as significant statistical test results), concentrations of parameters that increased with distance from the Near-field area were categorized as being positive patterns, while parameters with declining concentration with increasing distance were categorized as negative patterns.

8.2.4.2.2 Within Near-field Area Temporal Comparison (2015 to 2018)

A qualitative temporal evaluation of Near-field data collected between 2015 and 2018 was undertaken to evaluate whether sediment parameter concentrations within the Near-field area have increased over time. Prior to completing this analysis, values below the RDL were substituted with one-half of the RDL. Box-and-whisker plots of raw data and fine-normalized data were generated for each sediment parameter to facilitate this evaluation.

Comparison to FEIS Predictions

During the development of the FEIS, predictions of contaminants of potential concern in sediments were not completed due to the high degree of uncertainty associated with these predictions. In addition, the FEIS noted high variability in evidence for changes in sediment quality from other mines in Northern Canada (Agnico Eagle 2014, Volume 7, Section 7.4.6.1.3). The FEIS also predicted that changes to water quality would result in final water concentrations lower than the applicable guidelines and that the TSS in the effluent would be regulated to meet the MDMER. Based on this information, the FEIS qualitatively predicted that sediment quality in the vicinity of the diffuser would be comparable to baseline sediment quality.

8.2.4.3 Comparison to Normal Ranges

Normal ranges were calculated for each sediment quality parameter using available baseline data for Meliadine Lake stations; i.e.,1994, 1998, 2008, 2011, 2013, 2015, 2016, and 2018.

Prior to completing statistical analyses and normal range calculations, one half the RDL was substituted for non-detect values in the dataset. Sediment quality data were then normalized to the fraction of fine sediments ([silt + clay]/100) to account for the relationship of most parameters with percent fines. This procedure is aligned with the recommendation provided by the EEM TGD (Environment Canada 2012) to account for sediment particle size influence. If a linear regression between concentration of a parameter and percent fines was significant at $\alpha = 0.1$, normalization was achieved by dividing each individual metal concentration with the respective fine sediment proportion of the sample.

Methods for estimating normal ranges for sediment quality followed the methods of Barrett et al. (2015) and are consistent with the approach used for calculating normal ranges for other AEMP components (i.e., water quality, benthos, and plankton). A summary of the methods used in this assessment is provided below:

- When data were normally distributed, the normal range was estimated as the 80% prediction interval (PI) of the dataset. Normality was assessed using the Shapiro-Wilk test, using $\alpha = 0.05$ to indicate a significant departure from normality.
- When the baseline data were not normally distributed, but normality could be achieved after Box-Cox transformation (Box and Cox 1964), the normal range was calculated on the Box-Cox transformed data and the upper and lower bound of the normal ranges were back-transformed.
- If neither the untransformed data or Box-Cox transformed datasets were normally distributed, the normal range boundaries were defined as the 10th and 90th percentile of the baseline data. In cases where the percentile method was used, a dataset of 1,000 samples was randomly generated from the normal range dataset and the 10th and 90th percentile were calculated from this distribution of 1,000 samples to estimate the normal range.

It should be noted that the normal ranges provided in this report are considered provisional during the initial monitoring years under the AEMP, due to the limited sample sizes used in the calculations. The normal range is intended to estimate the range of natural spatial and temporal variability, and the more reference data are incorporated into the calculation, the more accurate the estimate becomes. These normal ranges may be redefined in future reports to allow for the inclusion of additional monitoring data from reference areas as they become available.

Each calculated normal range was evaluated for representativeness. For example, some parameters had variable RDLs, or parameters with low detection frequency could have calculated upper bound normal ranges that were less than the RDL, whereas actual concentrations could be anywhere between zero and the RDL. Consequently, the calculated normal ranges for parameters with non-detect concentrations in the dataset were revised according to the following criteria:

- If all values were less than the RDL, then the lower bound of the normal range was set to zero and the upper bound was set to the RDL value.
- If the lower bound of the normal range was less than the RDL, then it was set to zero.
- If the upper bound of the normal range was less than the RDL, then it was set to the RDL value.
- If the dataset included a mix of RDLs and all the values were non-detect, then the normal range was set to zero (lower bound) and the most common used RDL (upper bound).
- If the dataset included a mix of RDLs, and the upper bound of the normal range was between the lowest and highest RDL, then the upper bound of the normal range was set to the highest RDL.

If the dataset included a mix of RDLs, and the RDLs varied by more than an order of magnitude, then the data with the higher RDL was removed from analysis and the normal range was re-calculated.

8.3 Quality Assurance/Quality Assurance

8.3.1 Overview of Procedures

The QA/QC practices applied during this study and detailed results of the QC analyses for sediment quality samples collected in Meliadine Lake are provided in Appendix 8A. QA components of the program included the use of trained personnel, standard procedures, and an accredited analytical laboratory; QC components included assessments of duplicate samples.

8.3.2 Summary of Results

Detailed results are provided in Appendix 8A. The results of the review of field and laboratory data indicated that field measurements and laboratory data were of high quality. Key findings from the 2018 QA/QC results are as follows:

- Overall good repeatability was observed in the analysis.
- Two sets of duplicate samples were collected and analyzed, equivalent to 20% of the total sampling effort for 2018. In duplicates analyzed, only 4% of the results had an RPD of more than 30% when one or both parameter concentrations were above five times the DL.
- Re-analyses were requested for ALS for particle-size analysis of MEL-01-09 and cadmium of MEL-05-02, results were confirmed by the re-analyses.

8.4 Results and Discussion

8.4.1 Summary Statistics and Sediment Quality Guideline Comparison

For the 2018 sediment data, descriptive statistics (minimum, median, mean, maximum, standard deviation, and sample count) were calculated for the Near-field, Mid-field, and reference areas and the results were compared to applicable PELs and ISQGs (Tables 8.4.1 to 8.4.3). The full 2018 dataset is presented in Appendix 8B and the time-series plots for the parameters analyzed are presented in Appendix 8C. Box-and-whisker plots showing parameter concentrations by area in 2018 are presented in Appendix 8D.

Table 8.4-1: Sediment Quality Summary for the Near-Field Exposure Area in 2018

Bolded values are higher than sediment quality guidelines.

(I) = value higher than the Interim Sediment Quality Guideline.

(P) = value higher than the Probable Effects Level.

Sediment quality data shown in this table were rounded to reflect laboratory precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Measured concentrations equal to the guideline values were not identified as exceedances.

ISQG = Interim Sediment Quality Guideline; PEL = Probable Effects Level; µg/g = micrograms per gram; - = no guideline or data.

Zinc	µg/g	123	315	48	44	20	70	17	10	-	-

Bolded values are higher than sediment quality guidelines.

(I) = value higher than the Interim Sediment Quality Guideline.

(P) = value higher than the Probable Effects Level.

Sediment quality data shown in this table were rounded to reflect laboratory precision after comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Measured concentrations equal to the guideline values were not identified as exceedances.

ISQG = Interim Sediment Quality Guideline; PEL = Probable Effects Level; µg/g = micrograms per gram; - = no guideline or data.

8.4.1.1 Particle-size and Organic Carbon

Sediment particle-size analysis revealed different substrate types across the AEMP study area. As observed in previous years, a greater percentage of silt was observed in the Near-field and Mid-field areas compared to the reference areas, which tended to be more dominated by sand (Figures 8.4.1 and 8.4.2). In 2018, TOC ranged from 0.3% and 9.0% at the stations sampled, but most values were between 4.0% and 8.0%. This range is consistent with results obtained in the previous years for Meliadine Lake (Figure 8.4-3). Of the areas sampled in 2018, the reference areas were more variable in TOC compared to the exposure areas.

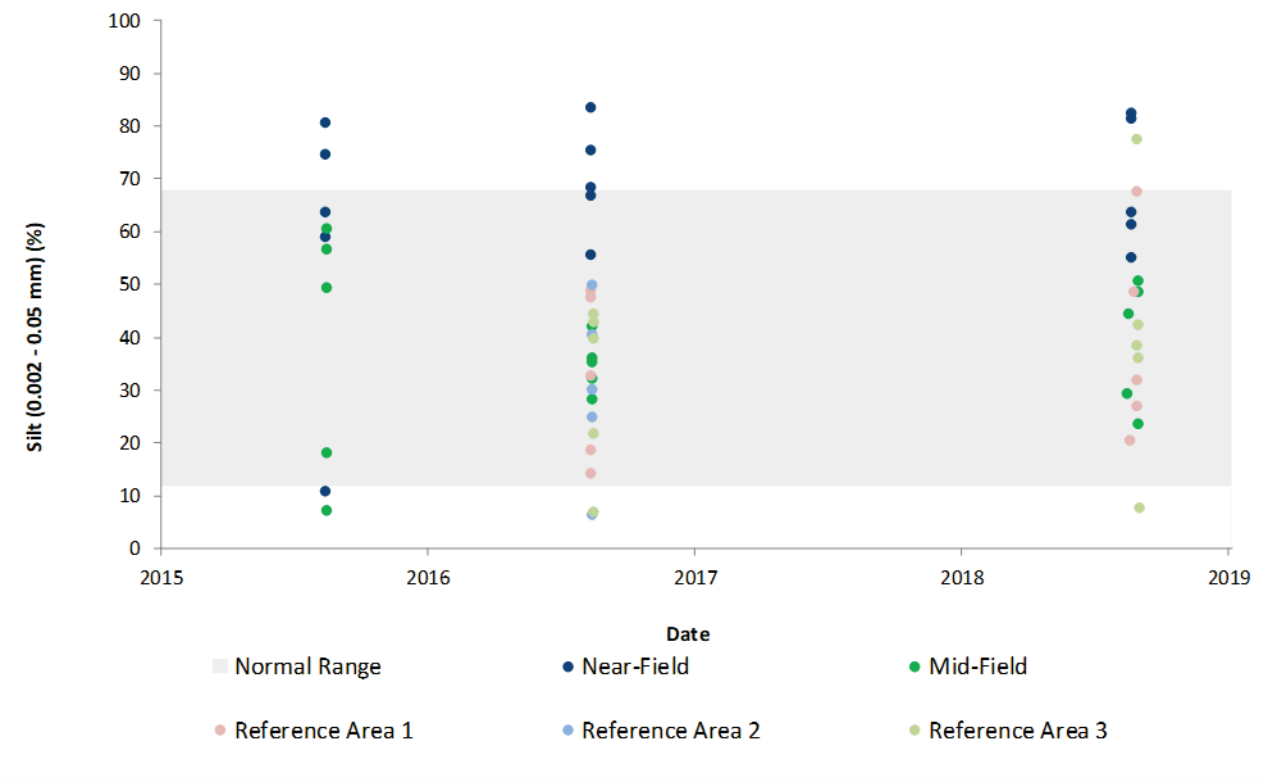

Figure 8.4-1: Silt (%) in Meliadine Lake, 2015 to 2018

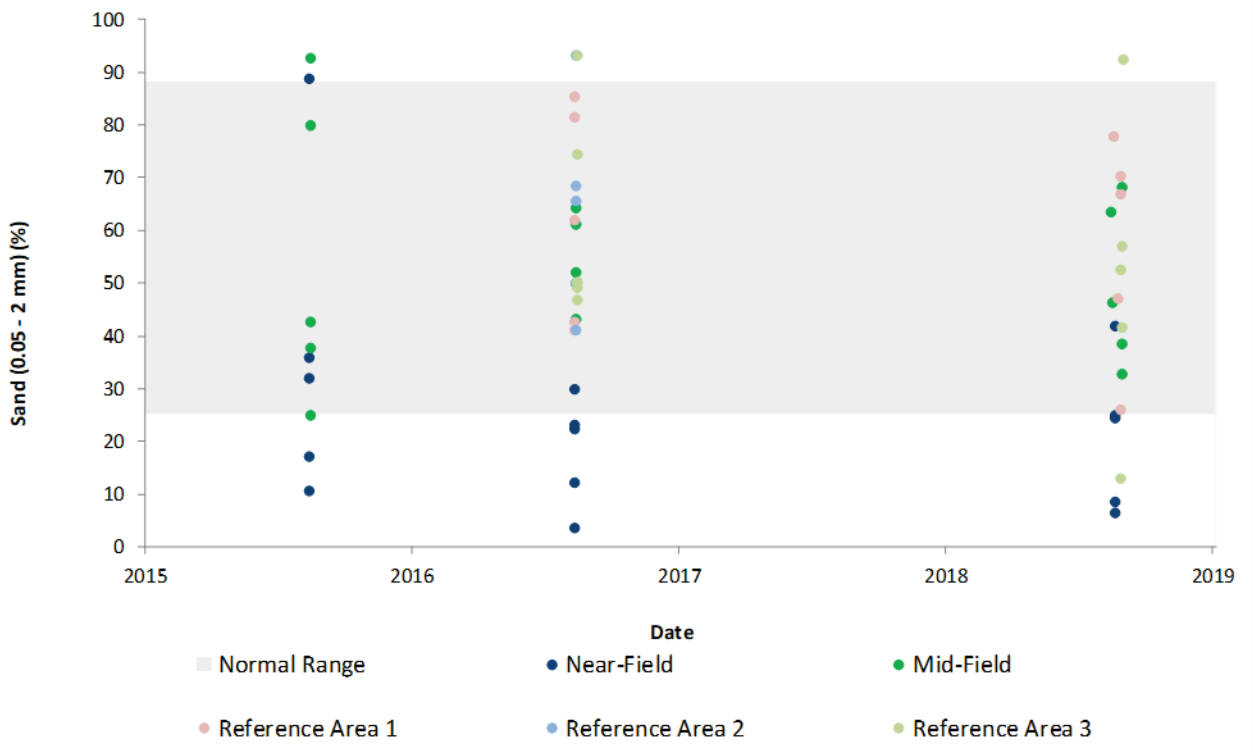

Figure 8.4-2: Sand (%) in Meliadine Lake, 2015 to 2018

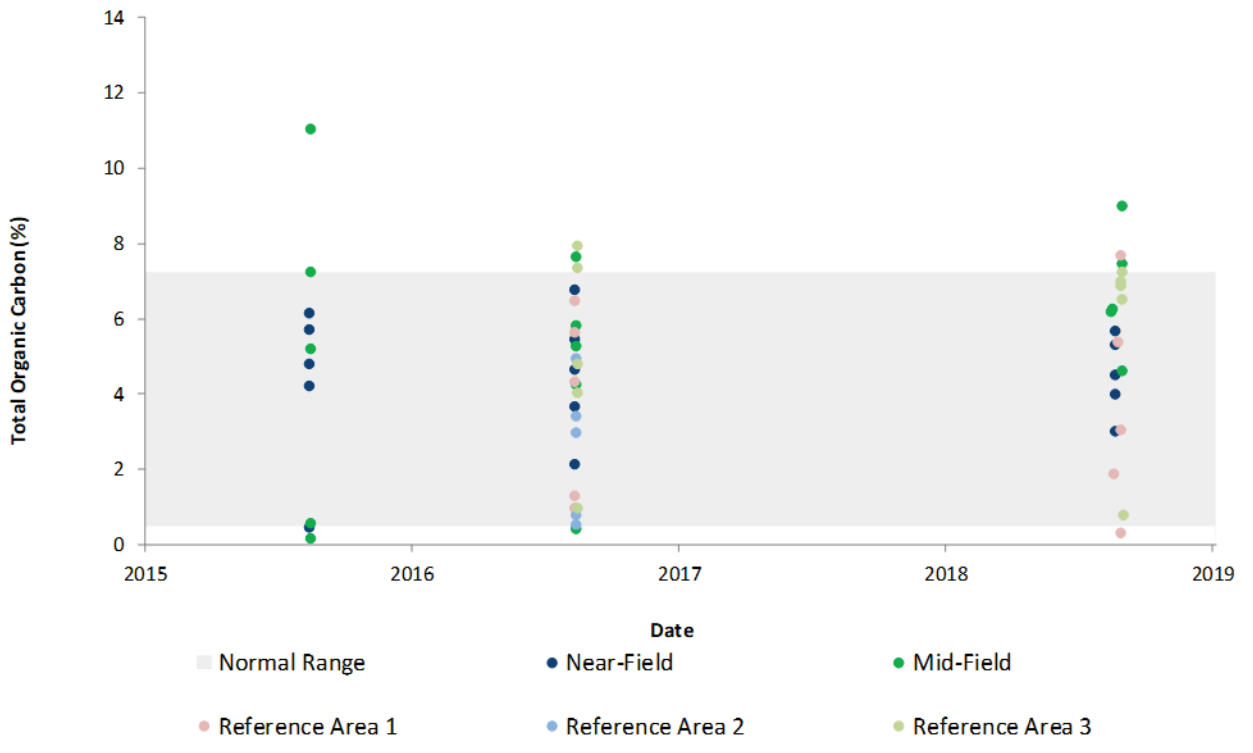

Figure 8.4-3: Concentrations of Total Organic Carbon in Meliadine Lake, 2015 to 2018

8.4.1.2 Metals

Concentrations of metals and metalloids[4] at exposure and reference stations sampled in 2018 were below sediment quality guidelines with the following exceptions:

- Arsenic concentrations at the five Near-field stations exceeded the ISQG. Concentrations at four of the five stations also exceeded the PEL (Figure 8.4.4). The maximum arsenic concentration of 33 µg/g was 5.6 times the ISQG and 1.9 times the PEL. For chromium and copper, sediments at all five Near-field stations were above the ISQGs but were below their respective PELs.
- In the Mid-field area, arsenic and copper concentrations exceeded ISQG at the five stations sampled in 2018 but did not exceed PEL. Chromium concentrations were also above the ISQG but below the PEL at four of the five stations sampled.
- At one Near-field station, sediment cadmium concentration was equivalent to the ISQG.
- In Reference Area 1, only one out of five samples exceeded the ISQG for arsenic and chromium, whereas for copper concentrations at three of the five stations were above the ISQG.
- In Reference Area 3, ISQGs were exceeded at four of the five stations sampled for arsenic and three of the five stations for copper. The arsenic concentration at one station of 23 µg/g was also above the PEL by a factor of 1.4.

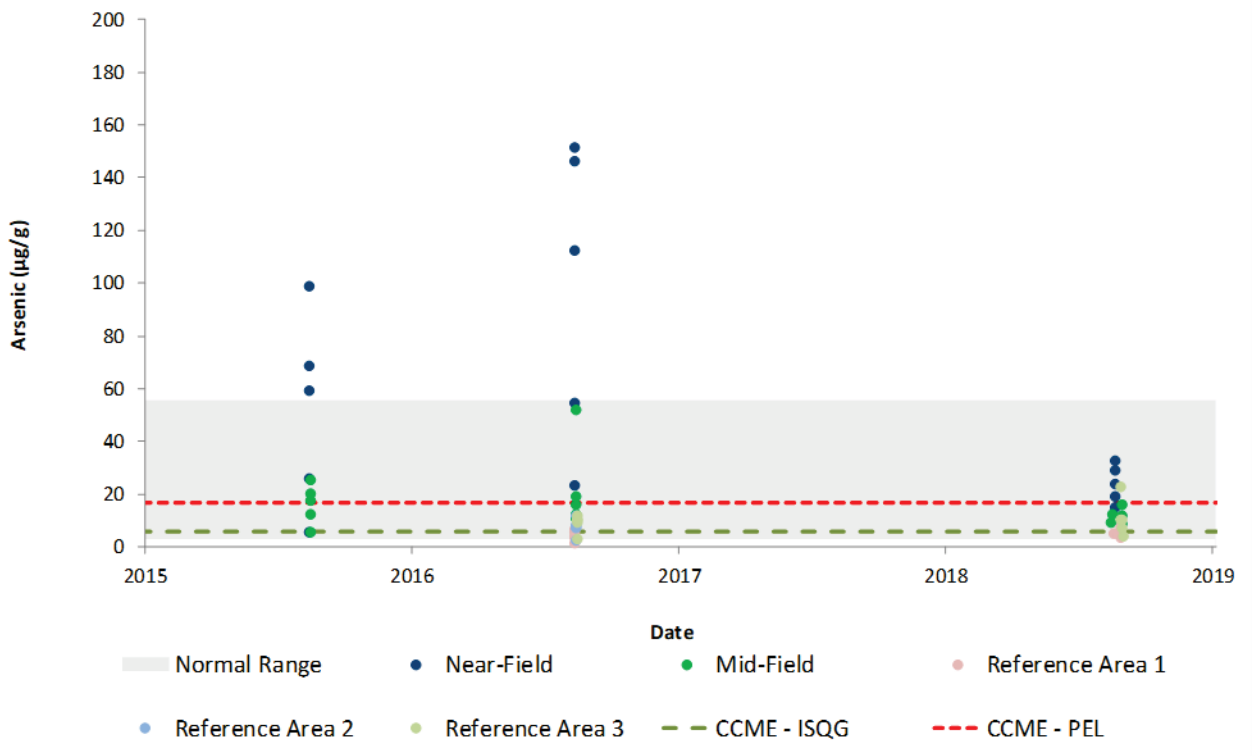

Figure 8.4-4: Concentrations of Arsenic in Meliadine Lake, 2015 to 2018

Metals, metalloids (e.g., arsenic), and non-metals (e.g., selenium) are referred to as “metals” in this document.

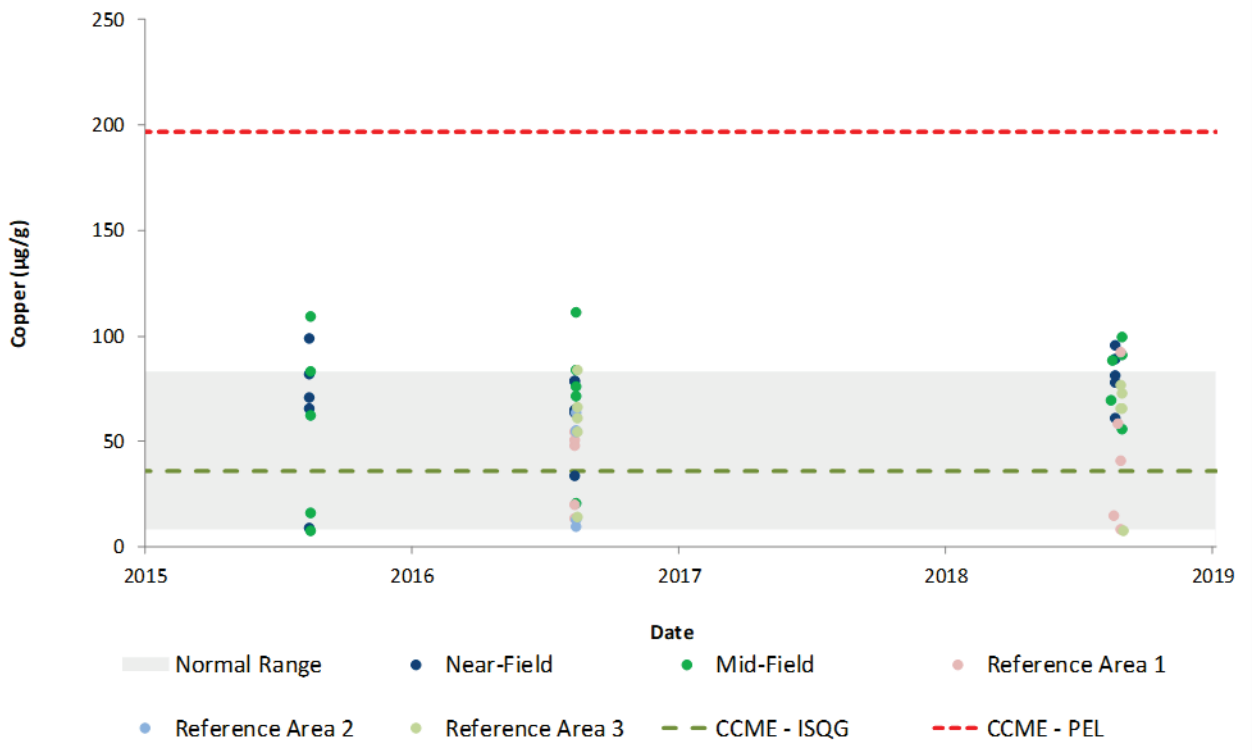

Figure 8.4-5: Concentrations of Copper in Meliadine Lake, 2015 to 2018

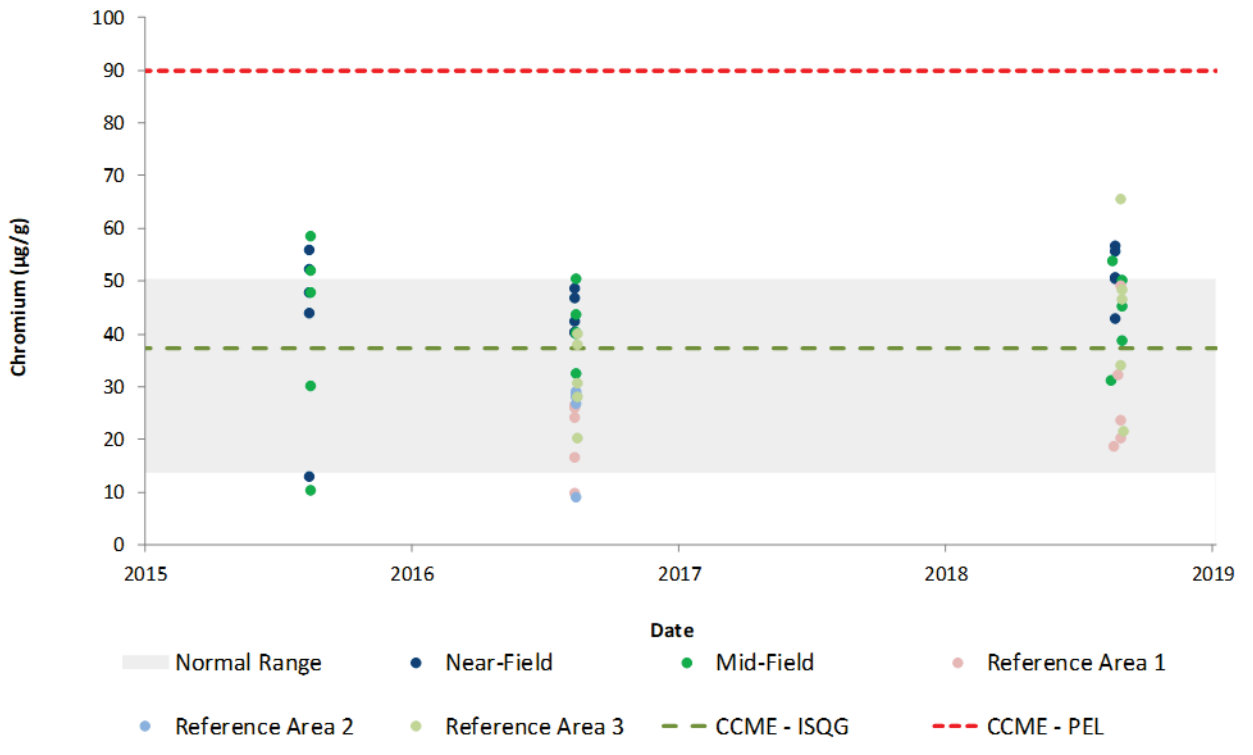

Figure 8.4-6: Concentrations of Chromium in Meliadine Lake, 2015 to 2018

Naturally elevated concentrations of arsenic, chromium, and copper have also been observed in sediments in other northern Canadian lakes. The occurrence of ISQG exceedances for several metals and the occasional arsenic PEL exceedance in the 2018 sediment data are consistent with observations made by Puznicki (1997) in an overview of sediment chemistry in lakes of the Northwest Territories (NT). The author reported that arsenic and nickel concentrations frequently exceeded ISQGs (>70% of samples) and occasionally PELs (>15% of samples); other metals also occasionally exceeded ISQGs (i.e., cadmium, chromium, copper, lead, mercury, zinc).

With specific reference to arsenic, sediment concentrations reported in the Near-field area under baseline conditions in 2015 and 2016 were above sediment quality guidelines and extended above the concentration range reported for this area in 2018 (Figure 8.4-4 and Table 8.4-1). Although to a lesser extent, arsenic guideline exceedances were also reported under baseline conditions for the Mid-field and reference areas located further away from the mine (Figure 8.4-4 and Table 8.4-3). Naturally elevated arsenic concentrations were previously identified in sediments and soils within the vicinity of the Meliadine Mine Site during baseline sampling and development of the FEIS (Agnico Eagle 2014, Volume 6, SD6-3; Volume 7; Section 7.4). For example:

- Mean sediment arsenic concentration in Meliadine Lake exceeded the ISQG by a factor of two, and arsenic concentrations in Peninsula Lakes exceeded both ISQG and PEL.
- Soil arsenic concentrations in the vicinity of the Meliadine Mine Site ranged from 10 to 10,000 µg/g, with an average of 30 µg/g.

Naturally high concentrations of arsenic associated with gold deposits are a common feature (Straskraba and Moran 1990), as the arsenic-associated minerals arsenopyrite, pyrite, pyrrhotite, and chalcopyrite are directly associated with gold mineralization (Agnico Eagle 2014).

8.4.1.3 Relationship Between Particle Size and Metal Concentrations

Particle-size is a key factor in determining the distribution of metals in lake sediments, with a propensity for most metals to preferentially accumulate in finer sediments, such as silt and clay. As well as sediment texture, TOC content can also influence metal concentrations in sediments, with higher concentrations typically associated with higher TOC values. However for the AEMP, TOC values were relatively consistent across study areas in 2018 when compared to particle-size, which, as described in Section 8.4.1.1 differed between the Near-field area and the other study areas located farther away from the Mine. Similar observations regarding differences in particle-size between areas were also made by Golder (2018c) for data collected under baseline conditions. Golder (2018c) demonstrated that a higher proportion of finer sediments in the Near-field area was associated with proportionally higher concentrations of some metals compared to the reference areas. As a consequence, 2015 and 2016 sediment metals data were normalized prior to statistical analysis for the 2018 assessment to address the potentially confounding factor of varying particle-size distribution among sampling areas.

Normalization of metal data is a procedure that aims to reduce the influence of particle-size and mineralogy on metal concentrations, and thus allows assessing the differences between natural and anthropogenic inputs (Ho et al. 2012). It is well documented that finer sediments tend to offer more binding sites for metals, and so are often highly correlated with metal concentrations (Environment Canada 2012). The use of fine sediments to normalize sediment chemistry was appropriate for the 2015 to 2018 dataset, because strong correlations were observed between metal concentrations and percent fines (Table 8.4-4, Figure 8.4-7). This is the normalization method suggested by EC (2012) to address differences in substrate composition. An alternative normalization method is to normalize sediment data to conservative elements such aluminum, iron or lithium (Ho et al 2012). The high correlation between aluminum and fines in 2018 (r = 0.929; Figure 8.4-7) suggests that both

normalization procedures would yield similar results, which was confirmed by the scatter-plots (Appendix 8E) and correlation matrices for 2018 and all available data (Table 8.4-4).

Table 8.4-4: Spearman Rank Correlations between Percent-fines or Aluminum and Sediment Quality Variables, 2015 to 2018 (n=55) and 2018 only (n=20).

Sediment Variable	2015 to 2018				2018

Fines (%) = silt + clay, TOC = total organic carbon.

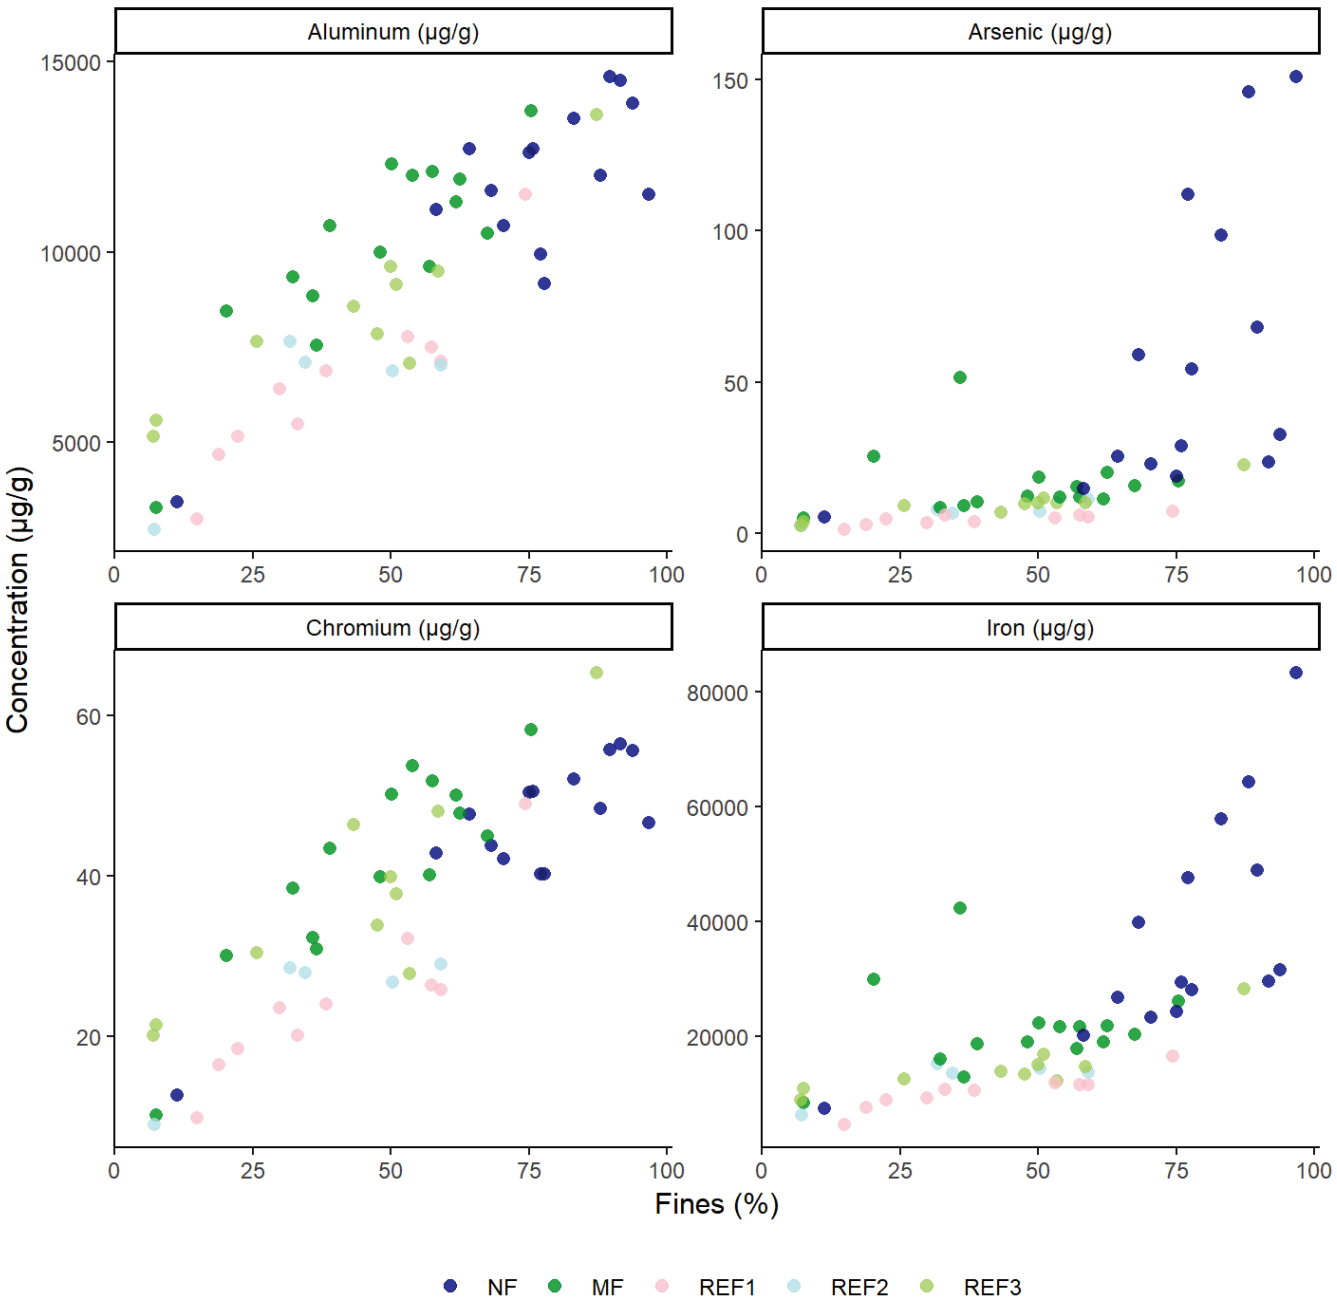

Figure 8.4-7: Scatter-plots of Selected Sediment Metal Concentrations versus Percent-fines in Meliadine Lake, 2015 to 2018

8.4.2 2018 Spatial Comparison

8.4.2.1 EEM

The Cycle 1 EEM Study Design is based on a control-impact comparison of Near-field area (MEL-01) and Reference Area 1 (MEL-03). Summary statistics calculated for both areas are presented in Table 8.4-5.

In 2018, the following parameters had a mean concentration in the Near-field area that was greater than two times the Reference area mean, up to a maximum of 4.6 times the reference mean (arsenic):

- clay
- arsenic
- bismuth
- cadmium
- cobalt
- iron
- lead
- manganese
- mercury
- molybdenum
- nickel
- selenium
- thallium
- uranium
- zinc

Sediments at Near-field area stations were mostly silt-dominated in comparison to sediments sampled at Reference Area 1, which had a higher percentage of sand (Table 8.4-5). Mean% fines in the Near-field area was approximately 1.9 times higher than mean% fines in Reference Area 1. Correspondingly, mean% sand in the Near-field area was approximately 2.5 times lower than mean% sand in Reference Area 1. Higher metal concentrations and finer sediments documented in the Near-field area in 2018 relative to the reference areas also occurred prior to the Mine effluent discharge under baseline conditions in 2015 and 2016 (as discussed in Section 8.4.1.2).

For arsenic, the 2018 Near-field concentrations were substantially lower than those reported under baseline conditions, as discussed further in Section 8.4.1.2 and shown in Figures 8.4-4 to 8.4-6. Sediment arsenic concentrations were also less variable between Near-field stations in 2018 compared to the previous two monitoring years.

Table 8.4-5: Sediment Quality Summary for the Cycle 1 EEM Exposure and Reference Areas in 2018

Vanadium	µg/g	-	-	57	58	47	66	6.9	5	25	30	22	45	9.0	5	1.9
Zinc	µg/g	123	315	94	91	71	101	12	5	41	41	20	70	21	5	2.2

(a) Not calculated due to high percentage of results below the detection limits

Bolded values are higher than sediment quality guidelines.

Shaded values are greater than 2 times those in the Reference Area. Calculations were based on mean results.

(I) = value higher than the Interim Sediment Quality Guideline.

(P) = value higher than the Probable Effects Level.

Sediment quality data shown in this table were rounded to reflect laboratory precision after comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Measured concentrations equal to the guideline values were not identified as exceedances.

ISQG = Interim Sediment Quality Guideline; PEL = Probable Effects Level; µg/g = micrograms per gram; EXP = Exposure Area; REF = Reference Area; - = no guideline or data.

8.4.2.2 AEMP

A spatial comparison between the three sampling areas (i.e. Near-field, Mid-field and pooled Reference) was completed for the 2018 sediment quality dataset. As discussed above, sediment metals data were normalized to percent-fines prior to conducting the analysis. The results are summarized in Table 8.4-6 and presented visually in box-and-whisker plots in Appendix 8D. The results identified as outliers are presented in Appendix 8F, the overall test results are also available in Table 8F-1, while the results obtained after outlier removal are presented and discussed below (Table 8.4-6).

A total of thirty-two parameters underwent statistical analysis to compare normalized metal concentrations between the exposure areas and the pooled reference areas[5]. Nineteen parameters met ANOVA assumptions for normality and homoscedasticity while thirteen parameters failed to meet these assumptions and were therefore tested using the non-parametric Kruskal-Wallis test.

A significant statistical difference between study areas was identified at $\alpha = 0.1$ for the majority of parameters, with the exception clay content and several normalized metals (i.e., aluminum, lithium, magnesium, potassium, titanium, vanadium) (Table 8.4-6). Where significant differences between the reference and exposure area were identified, the following were noted:

- Statistical testing confirmed differences observed in particle-size composition between the Near-field, Mid-field, and pooled reference areas.
- Sediments in the Near-field area had a significantly greater% of silt and a significantly lower% sand relative to the other areas.
- Percentages of silt and sand did not differ significantly between the Mid-field and pooled reference areas.
- Normalized TOC concentrations were significantly different for all comparisons, and followed the order Mid-field >Near-field >Reference area. Thus, the Mid-field had significantly higher TOC relative to the other areas.
- Normalized arsenic concentrations were significantly higher in the Near-field area compared to the pooled reference areas.
- For normalized cadmium, both the Near-field and Mid-field areas had higher concentrations relative to the pooled reference areas.
- Chromium and copper had greater normalized concentrations in the Mid-field area relative to the Near-field area, while Near-field area and pooled reference area concentrations were not significantly different.
- For three parameters, the outlier removal affected the test results; these are arsenic, cobalt and nickel. For these parameters, the overall comparison was not significant when the outliers were included, but tests were significant without the outliers.

The combined presence of higher concentrations of some normalized metals and TOC in the Mid-field area suggests that the TOC content could be partly responsible for the observed metal concentrations, given that some metals preferentially accumulate in sediments with elevated organic matter (Ho et al. 2012). Concentrations of several metals, both within and between the AEMP study areas, have consistently been shown to exhibit a degree

[5] Antimony, bismuth, silver and tin were removed from the parameter list due to the high percentage of results below DL.

of natural variability in part due to variability in substrate type and organic matter content. The exception is arsenic, which even when normalized for fine sediment content, still had significantly higher concentrations compared to the reference areas. Higher concentrations of arsenic in Near-field sediments even after normalization could be an indication of local sources (i.e., different mineralogy in a local scale) or effects of mine effluent discharge. Arsenic was not, however, elevated in the effluent or in the lake water (concentrations were also below the effluent discharge limit and the AEMP benchmark); therefore, the higher concentrations in the Near-field area were not linked to the Mine effluent discharge. Furthermore, as discussed in Section 8.4.1, a concentration gradient for sediment arsenic with higher concentrations within the Near-field area was evident before start-up of the Mine effluent discharge in 2018.

Statistical outliers were identified for a number of metals. As described in Section 8.2.4.2.1.2, the among-area statistical comparisons were completed with and without the relevant outliers, and the results are provided in Appendix 8F. The removal of the outliers reduced the *P*-value which resulted in three parameters (arsenic, cobalt, and nickel) showing a significant difference between areas that was not detected when the outliers were included in the analysis. However, excluding outliers did not substantially influence responses to the AEMP key questions for the sediment quality component, or the overall conclusions of the 2018 AEMP.

Table 8.4-6: Sediment Quality Comparison among Near-field, Mid-field Exposure Areas and the Pooled Reference Areas, 2018

Parameter	Unit	Overall Model		Outliers Removed	Near-field		Mid-field		Pooled Reference Area		Pairwise Comparisons					
											Near-field to Mid-field		Near-field to Reference		Mid-field to Reference

Note:
Shaded values indicate that the magnitude of difference was greater or equal to ±30%
Bolded values were significantly different at α = 0.1.
Italicized values were detection limits set as one-half the detection limit
Parameters with greater than 50% of the dataset below the detection limit were excluded from analysis and are not shown in this table.
ANOVA = analysis of variance; µg/g dw%Fines = microgram per grams dry weight normalized to percent-fines; NS = post-hoc test indicated no significant difference among areas; - = pairwise comparison was not conducted because overall model indicated no significant difference.

8.4.3 Temporal Comparison in the Near-field Area

Box-and-whisker Plots of the Near-field data are provided in Appendix 8G to facilitate interpretation of the Near-field area data over time. Box plots were generated for all reported sediment parameters with the exception of antimony, bismuth, silver and tin, which had a high percentage of results below RDLs.

Particle size parameters and TOC concentrations were reasonably consistent over time, and no clear trend was visible (Figure 8.4-8 and 8.4-9, Appendix 8G). These results suggest that the changes in the sampling station locations within in the Near-field area between 2016 and 2018 did not substantially influence the sediment substrate type sampled.

A decrease in arsenic concentrations between 2016 and 2018 within the Near-field area was observed (Figure 8.4-10, Appendix 8G). Arsenic concentrations in 2018 were lower than those reported in 2016 and 2015. These results highlight the natural variability of metal concentrations within the Near-field area of Meliadine Lake over time, given that grain size and TOC were reasonably consistent between years. Iron and mercury also showed a decrease between 2016 and 2018, but not to the same extent as observed for arsenic.

Several other metals increased in concentration between 2016 and 2018; i.e., aluminum, beryllium, chromium, copper, magnesium, sodium, strontium, thallium, titanium, vanadium and zinc. These increases between years were also considered to reflect natural variability in sediment metal concentrations within the Near-field area over time. This conclusion is further supported by the identification of variability for several metals between baseline years prior to the mine effluent discharge.

The re-positioning of the Near-field stations in 2018 in response to the Plume Delineation Study and the Sediment Reconnaissance Survey may also account, at least in part, for differences in the concentrations of some metals between 2015/2016 and 2018. The geochemical baseline study that supported the FEIS observed small-scale variability in the chemical composition of the soil (or overburden) (Agnico Eagle 2014), consistent with the natural spatial and temporal variability identified for lake sediments by the AEMP.

8.4.4 Comparison to Normal Ranges

Normal ranges were calculated using data available from the AEMP Reference areas, 2015 and 2016 data from the Near-field and Mid-field AEMP exposure areas, and appropriate pre-2015 data included in the FEIS[6]. These data were included in the normal range calculation to make sure that the normal ranges captured the natural spatial and temporal variability in particle-size and some metals, as identified within and among AEMP study areas by this 2018 assessment. Normal ranges may be updated with future AEMP reference area data as they become available to further characterize natural variability.

The normal ranges are summarized in Table 8.4-7 and shown graphically on plots provided in Appendix 8C. The lower bound of the normal range for clay, beryllium, bismuth, boron, mercury, selenium and silver was set to zero because the calculated value was below the most frequent DL. Tin was the only parameter where all results were below the DL, thus the lower bound was set to zero and the upper bound was set to the DL.

Near-field measures of central tendency (i.e., means or medians) for the first year of the mine effluent discharge (2018) are also provided in Table 8.4-8 and were compared to the normal range for each parameter. The 2018 Near-field mean/median values for the following parameters exceeded their respective normal ranges: % fines, aluminum, beryllium, cadmium, nickel, silver, thallium, and zinc. In the Mid-field area, only the copper mean/median value was above the normal range upper boundary.

Where mean/median values exceeded a normal range, values were only marginally above, by less than a factor of 1.2 (i.e., 20%), which is within the range of sampling variability that is typically observed in sediment quality data. As more sediment quality data are collected as part of the AEMP and the EEM program, emerging temporal trends will be evaluated relative to the normal ranges.

Table 8.4-7: Sediment Quality Normal Ranges for Meliadine Lake, 2018

Parameter	Unit (dry wt.)	Detection Limit[a]	Sample Size	Outliers Removed	Calculation Method	Normal Range		2018 Mean/Median[b]		
						Lower Bound	Upper Bound	Near-field	Mid-field	Reference Area[c]
Particle-size and Organic Carbon										
Sand	%	1	70	0	PI	25	88	21	50	54
Silt	%	1	70	0	PI(λ)	12	68	67	40	38
Clay	%	1	70	0	PI(λ)	0[d]	12	11	10	4.9
Fines (Silt + Clay)	%	1	70	0	PI	12	75	**79**	50	46
Total organic carbon	%	0.05	77	0	Percentile	0.49	7.2	4.5	6.2	5.9
Metals										
Aluminum	µg/g	50	60	0	PI	4,139	12,738	**12,960**	10,142	8,146
Antimony	µg/g	0.1	54	0	Percentile	0[d]	0.24	0.15	0.11	<0.1
Arsenic	µg/g	0.1	75	1	PI(λ)	2.9	56	23	11	6.1
Barium	µg/g	0.5	76	0	PI(λ)	25	134	115	109	64
Beryllium	µg/g	0.1	54	0	Percentile	0[d]	0.3	**0.33**	0.28	0.19
Bismuth	µg/g	0.2	54	0	Percentile	0[d]	0.35	0.32	0.23	<0.2

[6] With exceptions for antimony, beryllium, bismuth, cadmium, mercury, silver, thallium, tin and uranium analyzed under higher detection limits and with high percentage of non-detects. If data with high DLs was included it would artificially increase the upper lower of the normal ranges, therefore, following a conservative approach it was decided that these results should be excluded from analysis.

Table 8.4-7: Sediment Quality Normal Ranges for Meliadine Lake, 2018

Parameter	Unit (dry wt.)	Detection Limit[a]	Sample Size	Outliers Removed	Calculation Method	Normal Range		2018 Mean/Median[b]

(a) Most frequent report detection limit.

(b) Lake area means or medians were calculated using the back-transformed mean when the normal range was defined as the prediction interval using Box-Cox transformed data. The arithmetic mean was used when the normal range was defined using untransformed data.

(c) Reference area data were pooled from Reference Areas 1 and 3.

(d) The lower bound of the normal range was less than the detection limit; therefore, the lower bound of the normal range was set to zero.

(e) All values in the dataset were non-detect; therefore, the normal range was set from zero to the detection limit.

Bolded concentrations exceed the upper bound of the normal range.

Percentile = 2.5th and 97.5th percentiles; PI= 80% prediction interval; PI(λ) = 80% prediction interval on Box-Cox transformed data; µg/g = micrograms per gram.

8.5 Summary

8.5.1 EEM

The main findings of the Cycle 1 EEM sediment quality assessment to support the EEM benthic invertebrate assessment were the following:

- ISQG exceedances for arsenic, cadmium and chromium were identified in both exposure and reference areas. Near-field arsenic concentrations in sediments were also above the PEL, by less than a factor of 2. The arsenic concentration at one reference station was above the PEL, by a factor of 1.4. All other sediment metal concentrations reported in 2018 were below sediment quality guidelines.
- Differences between exposure and reference areas were mainly associated with natural variability, which was also observed in 2015 and 2016, prior to the Mine effluent discharge. For metals above sediment quality guidelines in the Near-field area, concentrations in 2018 were lower than those reported under baseline conditions in 2015 and 2016.
- Higher concentrations of metals and finer sediments in the Near-Field area compared to reference areas was also observed under baseline conditions prior to the 2018 Mine effluent discharge; therefore, Near-field area concentrations are considered representative of pre-discharge conditions.

8.5.2 AEMP

In 2018, the AEMP sediment quality assessment was undertaken as per the approved AEMP Design Plan for the first year of Mine effluent discharge (Golder 2016a). This AEMP summary is focused on providing responses to two AEMP key questions:

- Are concentrations of sediment quality parameters in Meliadine Lake less than benchmarks[7]?
- Are concentrations in the exposure area increasing over time relative to the reference areas?

Action levels are not discussed here, because Action Levels for sediment chemistry were not developed for the current AEMP Design Plan. With respect to FEIS predictions, the FEIS stated that sediment quality was not expected to change due to the Mine effluent discharge, but the FEIS did not generate quantitative sediment quality predictions for contaminants of potential concern. The FEIS conclusion of no expected mine effluent-related change in sediment quality is addressed below in relation to the two AEMP key questions.

Are concentrations of sediment quality parameters in Meliadine Lake less than benchmarks?

Data obtained for the sediment quality component in 2018 identified ISQG exceedances for arsenic, copper, and chromium. The PEL for arsenic was exceeded in the Near-field area by less than a factor of 2 and at one reference station by a factor of 1.4. The 2018 Near-field mean/median values exceeded their respective normal ranges for % fines and several metals (i.e., aluminum, beryllium, cadmium, nickel, silver, thallium, and zinc). In the Mid-field area, copper exceeded its normal range. Reference area mean/median values were within normal ranges.

[7] Sediment quality guidelines are assumed surrogate for AEMP benchmarks for the purposes of this 2018 AEMP report.

Arsenic ISQG and PEL exceedances were more frequent in the Near-field area, possibly due to the combination of higher content of fine sediments and the known association of arsenic with gold deposits (i.e., the Near-field area might be more mineralogically enriched with arsenic compared to areas farther away from the mine). Arsenic concentrations within the same range were reported under AEMP baseline conditions and have been documented in other regional northern lakes. Thus, when 2018 Near-field data were compared to the arsenic normal range, the 2018 data were within that normal range calculated to represent the observed variability.

The majority of 2018 sediment metal concentrations were either below AEMP benchmarks or within normal range boundaries. Where mean/median values exceeded a normal range, values were only marginally above, by less than a factor of 1.2 (i.e., 20%), which is within the range of sampling variability typically observed in sediment quality data.

Are concentrations in the exposure area increasing over time relative to the reference areas?

Differences in particle-size composition among AEMP study areas was identified as a potential confounding factor in differentiating between mine-effluent related effects and natural variability within Meliadine Lake. After normalization to% fines to try to account for this potential confounding factor, arsenic, cadmium, iron, lead, manganese, mercury, nickel, thallium and uranium concentrations were still higher in the Near-field area.

Although some metals had higher concentrations in the Near-field area compared to baseline years, only a subset of these metals had mean/median values above their respective normal ranges. Normal ranges were calculated to represent natural variability observed in the sediment AEMP dataset to date. Where mean/median values exceeded a normal range, values were only marginally above, by less than a factor of 1.2 (i.e., 20%), which is within the range of sampling variability that is typically observed in sediment quality data. Thus, when natural variability was accounted for, the 2018 data indicated that concentrations in the Near-field area had not increased over time relative to the reference areas.

As more sediment quality data are collected by the AEMP, temporal trends will be further evaluated relative to normal ranges.

Overall, sediment quality in Meliadine Lake study areas was generally consistent with FEIS predictions.

8.6 Recommendations

No recommendations are provided for changes to benthic invertebrate monitoring under the EEM or AEMP.

9.0 BENTHIC INVERTEBRATE COMMUNITY

To date, AEMP BIC monitoring has been completed at Meliadine Lake in 2015, 2016, and 2018 to meet Type A Water Licence requirements (Type A Water Licence (2AM-MEL1631, Part I, Item 3), and MDMER EEM program requirements for the first year of the Mine effluent discharge in 2018. Sampling was completed in August of each year as per the AEMP Design Plan and the Cycle 1 EEM Study Design approved by the relevant regulatory agencies (Golder 2016; 2017b). Sample collection was aligned with AEMP water and sediment quality monitoring programs in August 2018.

Benthic invertebrate monitoring programs in 2015 and 2016 were intended to characterize baseline conditions within exposure and reference areas on Meliadine Lake. The BIC and supporting data generated were evaluated in the 2017 AEMP Annual Report to establish baseline conditions for the AEMP prior to the onset of mine effluent discharge (Golder 2018c). This section provides a summary of BIC data obtained in 2018, analysis of the 2018 data and baseline data, and an interpretation of the results as per the requirements of the AEMP and EEM programs. Data analyses presented in this section have been undertaken as per the AEMP Design Plan (Golder 2016a), the Cycle 1 EEM Study Design (Golder 2017a), and in response to comments from ECCC, INAC, and the KIA during review of the 2017 AEMP annual report (Golder 2018a). The report also follows the Cycle 1 EEM Study Design and considers comments provided by ECCC on the design document (Golder 2017a; 2018d).

9.1 Objectives

The main objective of the 2018 benthic invertebrate program with respect to fulfilling EEM requirements was to determine if the Mine effluent discharge has had an effect on the BIC in Meliadine Lake. The primary objective of 2018 benthic invertebrate program with respect to fulfilling AEMP requirements was to determine whether treated Mine effluent has the potential to cause short- or long-term effects on the BIC due to changes in water or sediment quality in Meliadine Lake.

Specific objectives for the BIC component of the 2018 AEMP are as follows:

- Compare benthic invertebrate communities in exposure areas in Meliadine Lake at the lowest trophic level (LTL) to within-lake reference areas, based on benthic invertebrate effect endpoints (e.g., invertebrate density, taxonomic richness, evenness, and similarity to reference communities)
- Verify predictions made in the FEIS relating to benthic invertebrate communities
- Meet the requirements of Part 2, Schedule 9 (d) of the MDMER regulations (Government of Canada 2018).
- Assess the efficacy of mitigation strategies proposed in the AEMP Design Plan (Golder 2016a) and the Environmental Management and Protection Plan to minimize the effects of the Mine on the aquatic environment
- Provide data to inform adaptive management intended to reduce or eliminate Mine-related effects on benthic invertebrate communities in Meliadine Lake

To achieve these objectives, analysis and interpretation of benthic invertebrate data in 2018 were focused on answering the following key question, as defined in the AEMP Design Plan (Golder 2016a):

Is the benthic invertebrate community affected by potential Mine-related changes in water and sediment quality in Meliadine Lake?

Field survey and data analysis methods employed to answer these key questions are described in Section 9.2. A summary of QA and QC assessment on the 2018 data is provided in Section 9.3. Results and discussion are presented in Section 9.4. A summary of the BIC results and conclusions are provided for both the EEM Cycle 1 EEM study and the AEMP in Section 9.5.

9.2 Methods

9.2.1 Sampling Design

Benthic invertebrate community monitoring was completed according to the methods outlined in the Cycle 1 EEM Study Design (Golder 2017a) and the AEMP Design Plan (Golder 2016a). The program consisted of one benthic sampling event with concomitant water quality and sediment sampling events in August 2018.

The Cycle 1 EEM study was designed to evaluate potential structural differences in Meliadine Lake communities between the area exposed to the MEL-14 effluent discharge (i.e., Near-field area) and Reference Area 1. Determination of effect was based on statistical analysis of BIC effect endpoints, such as density, richness, and evenness and the Bray-Curtis similarity index, as recommended by EEM TGD (Environment Canada 2012). Supporting endpoints were analyzed to provide additional input in assessment a range of effects that may result from Mine effluent discharge at the family level (FL).

For the 2018 AEMP program, BIC sampling was undertaken at two exposure areas (i.e., Near-field area and Mid-field area) and two reference areas (Reference Area 1 and Reference Area 3) in 2018 (Table 9.2-1, Figure 9.2-1). Although the study designs were consistent between the EEM and the AEMP, some modifications to these designs were made, as outlined below for each program.

Sampling in 2018 deviated from the Cycle 1 EEM study design as follows:

- A petite Ponar grab was used in place of an Ekman grab in 2018, following an evaluation of the success rate of each grab sampler during the 2018 Sediment Reconnaissance Survey (described further below; details are provided in Appendix 9A). Previous monitoring programs (2015 and 2016) used both the Ekman and Ponar grabs in Meliadine Lake. The Ponar grab was selected to provide better penetration and recovery of coarse sand substrates. Equipment dimensions and sampling area were unchanged from the original study design (15.24 × 15.24 cm; bottom sampling area of 0.0232 m²).
- The location of the Near-field area differed from that specified in the EEM study design (located close the MEL-D-1 diffuser location for the previous dewatering discharge). As approved by ECCC, the Near-field area was re-located for the 2018 sampling event to monitor the first year of Mine effluent discharge from the CP1 diffuser. Prior to the August 2018 EEM/AEMP sampling event, a Plume Delineation Study was completed to determine placement of the five stations within the Near-field area (Section 2.4.4). Near-field stations remained within the profundal zone to allow for compatibility of habitat characteristics with the Mid-field area and reference areas.
- Discrete samples to assess within-station variability were not collected at Near-field station MEL-01-06 as listed in the EEM study design, due to time constraints related to weather delays and an equipment malfunction. Instead, discrete samples were collected from Reference Area 3 station MEL-05-04.

Although the 2018 study design remained consistent with the AEMP Design Plan, there were some modifications to sampling station locations in response to the Sediment Reconnaissance Survey and the Plume Delineation Study. As described in the 2017 AEMP Annual Report (Golder 2018c), the Near-field and reference areas had

different substrates, with the Near-field area are being silt-dominated and the reference areas sand-dominated. To minimize this potential confounding factor, a Sediment Reconnaissance Survey was executed in July 2018 prior to the August benthic community sampling event. The purpose of the survey was to further investigate suitable and comparable stations for sediment and benthos sampling within the already established exposure and reference areas. Based on the survey results and consideration of the Plume Delineation Study, some sampling stations were relocated for the August 2018 sampling event to optimize the AEMP and EEM study designs. Detailed results of the Sediment Reconnaissance Survey are presented in Appendix 9A.

Specific deviations from the AEMP Design Plan in relation to station location were as follows:

- **Near-field Stations**: MEL-01-01 was retained because it was also retained as part of the water quality component near-field station re-alignment, after review of the 2018 Plume Delineation Study results. Furthermore, the July 2018 Sediment Reconnaissance Survey confirmed that sampling efficiency and grab fullness at this station were acceptable. The other four stations confirmed by the water quality realignment (i.e., MEL01-06, MEL01-07, MEL01-08 and MEL01-09) were adopted as 2018 sediment and benthic monitoring stations because they also had acceptable sampling efficiency and grab fullness. Furthermore, substrate composition was relatively consistent among the five 2018 near-field water quality stations.
- **Mid-field Stations**: 2018 sediment stations were selected to maintain alignment with water quality but to also avoid excessive sampling effort in retrieving acceptable grab samples. Therefore, MEL-02-06 and MEL-02-08 were chosen to replace MEL-02-01 and MEL-02-04 because of difficulty retrieving acceptable samples from MEL-02-01 and MEL-02-04. For stations that were re-sampled for consistency with previous years, locations were adjusted to within 5 to 10 m of the original sample locations based on sampling success.

As a result of the 2018 Sediment Reconnaissance Survey, sampling constraints such as target depth and sampler fullness were adjusted from the previous AEMP program to allow for future success in sediment-limited areas. A target depth range of 7 to 10 m and a grab sampler fullness of >40% was set as the project criteria for sampling; the AEMP Design Plan previously specified 8 to 10 m depth. To assess the potential effect of this adjustment on monitoring results, depth was added as a parameter to the correlation analysis run to evaluate habitat relationships, and sampler fullness was used as a screening variable when identifying outliers prior to data analysis (Appendix 9C).

Two of the three reference areas specified in the AEMP Design Plan were sampled in 2018. Benthic invertebrate samples were not taken from Reference Area 2 (MEL-04) due to meteorological challenges; i.e., strong winds during August limited the time available for sediment sampling, such that only two of the three reference areas could be sampled. Reference Area 2 (MEL-04) was removed from the sampling program because it was the least similar to the Near-field area in 2016, and during the 2018 Sediment Reconnaissance Survey it was challenging to meet the sampling success criteria in this area (Appendix 9A).

QA/QC procedures described in Section 9.3 were followed during the 2018 benthic invertebrate monitoring program.

Table 9.2-1: Benthic Invertebrate Community Sampling Stations in Meliadine Lake, 2018

9.2.2 Field Methods

As discussed above, following the July 2018 sediment reconnaissance and plume delineation surveys, stations in the Near-field and Mid-field areas were relocated based on proximity to the MEL-14 diffuser location, sampling efficiency and retrieval success, and comparable sediment composition. The results of the Sediment Reconnaissance Survey are described in Appendix 9A and the Plume Delineation Study is described further in Section 2.4.4.3.2. Benthic invertebrate community samples were collected in the fall, which is the period of highest community diversity and stability (MOE 2007).

Habitat characteristics were standardized to the extent possible for sediment particle size and water depth (i.e., between 7 and 10 m) to reduce habitat-related variability in the BIC data. Benthic invertebrate samples were collected using a Petite Ponar grab (15.24 × 15.24 cm; bottom sampling area of 0.0232 m²). At each station, five subsamples were collected and sieved through a 500 µm mesh screen in the field. At the majority of stations sampled, subsamples were combined to form a composite sample from material retained by the mesh, placed in a 500 mL sample bottle, and preserved with 10% neutral buffered formalin.

Pooling of subsamples in the field to form a single composite sample for taxonomic analysis from a station is commonly done to reduce analytical cost, without an effect on study results. Analysis of data collected during EEM and AEMP surveys is based on station as the unit of replication and does not require data for separate subsamples. Analyses of separate subsamples is useful to initially evaluate within-station variation, but once the number of subsamples required is determined, collection of subsample data is no longer necessary. As per the Cycle 1 EEM Study Design (Golder 2017a) and AEMP Design Plan (Golder 2016a), individual subsamples were collected at one station MEL-05-04, and were preserved separately. Samples were shipped to Cordillera Consulting, Summerland, British Columbia, for taxonomic identification and enumeration of invertebrates.

Sediment quality samples were also collected using a Petite Ponar grab, concurrently with BIC samples, to characterize particle size and TOC as outlined in Section 8.0. Environmental data and observations, such as habitat characteristics and field water quality data, were also recorded in conjunction with benthic invertebrate sampling to provide supporting information. Specifically, the following in-situ surface water quality measurements, habitat characteristics, and other information were recorded at each sampling station:

- sampling date
- GPS coordinates, recorded as UTM
- water depth
- presence of aquatic vegetation and algae
- near-bottom in situ water quality measurements of water temperature, DO, pH and specific conductivity
- observations of the sediments for colour, consistency, and odour

9.2.3 Laboratory Methods

Samples were submitted to Cordillera Consulting Inc. (Cordillera; Summerland, BC) for taxonomic identification and enumeration of invertebrates to the lowest practical level (typically genus or species). Cordillera team members are certified by the Society for Freshwater Science in taxonomic identification and have over seven years' experience in sample processing for EEM programs. Benthic invertebrate samples were initially processed to remove the preservative and remaining fine sediment. Samples with high inorganic content were elutriated to separate the organic material from the inorganic material prior to sorting. Inorganic material was checked for shelled or cased invertebrates that may have been too heavy to elutriate; this heavier material was included in the remaining sample to be sorted.

Subsampling was not necessary for any of the 2018 samples. Benthic invertebrates were identified to the genus level where possible. If organisms could not be identified to the genus level, they were identified to the next higher taxonomic level of identification (i.e., family, order, class or phylum). A reference collection was prepared, consisting of representative specimens from each taxon. The reference collection was archived by the taxonomist for possible comparison with BIC data from future studies and for QC of future taxonomic identifications. Further details regarding taxonomy methods and reference collection results are provided in Appendix 9B.

Raw invertebrate abundance data were received from the taxonomist in electronic format. To meet EEM requirements, data were entered into the latest version of ECCC EEM Metal and Diamond Mining Data Entry Software. For reporting purposes, data were stored in Excel spreadsheets.

9.2.4 Data Analysis

9.2.4.1 Review of Field Data

Field data collected in 2018 were pre-screened based on adherence to acceptability criteria for the collection of grab samples:

- acceptable grab sample volume of a minimum 40% fullness
- sample depth between 7 and 10 m

The 2018 field data met these acceptability criteria. With respect to the AEMP baseline dataset brought forward to support interpretation of the 2018 benthic data, there was an absence of sufficient depositional sediments at three locations in 2015 (i.e., stations MEL-01-05, MEL-02-04 and MEL-02-05), resulting in samples with <10% fullness of the petite Ponar grab. As a result, these samples did not meet the ">40% fullness" criterion and were eliminated from the dataset used for 2018 reporting in this section. All samples collected in 2016 and 2018 met this criterion and were considered to be acceptable.

9.2.4.2 Review of Taxonomic Data

The 2018 taxonomic dataset was pre-screened prior to analysis and adjustments were made as described below:

- The composite benthic sample taken at station MEL-05-05 in 2018 contained only one benthic invertebrate organism. This was despite the sample meeting acceptability criteria for suitable particle size, grab fullness and sampling an area equivalent to five grab samples (i.e., 0.116 m^2). Data for this sample were therefore considered to be anomalous, potentially resulting from inadequate sample preservation, and this station was excluded from the data analysis.
- Data for Nematoda and Ostracoda were removed from the dataset before data analysis. These meiofauna are not reliably enumerated using 500 µm mesh sampling gear (Environment Canada 2012).

- Copepoda and Cladocera were excluded from the dataset before data analysis because they are non-benthic organisms.
- *Baetis sp.*, *Zapada columbiana*, and *Brachycentrus occidentalis* were removed from the dataset because they are not considered to be part of the resident BIC in Meliadine Lake. These taxa are typical of fast-flowing waters and were present in low abundance (i.e., one or a few individuals) in some samples as a result of incidental capture at the time of the survey. Each of these taxa represented <1% of the total invertebrate abundance.

9.2.4.3 Variable Selection

A summary of the benthic invertebrate variables calculated from the screened datasets is presented in Table 9.2-2. These variables align with the endpoints recommended of the EEM TGD (Environment Canada 2012), and meet MDMER and AEMP Design Plan requirements (Golder 2016, Government of Canada 2018), and provide supporting information to aid in the interpretation of the results.

Table 9.2-2: Summary of Benthic Invertebrate Variables Assessed for 2018 EEM and AEMP Programs

Variable	Cycle 1 EEM (Family Level)[a]	2018 AEMP (Lowest Level)[b]
Total invertebrate density (number of organisms per square metre)	Effect Endpoint (MDMER-required)	AEMP Variable
Total taxonomic richness (number of taxa per station)	Effect Endpoint (MDMER-required)	AEMP Variable
Simpson's diversity index (SDI)	Supporting Endpoint	AEMP Variable
Simpson's evenness index (SEI)	Effect Endpoint (MDMER-required)	AEMP Variable
Bray-Curtis Index, using the EEM method (i.e., comparisons to reference median) (BCI-EEM)	Effect Endpoint (not MDMER-required)	AEMP Variable
Bray-Curtis Index, using the pairwise method (BCI-PW)	Supporting Endpoint	AEMP Variable
Presence/absence by each taxon	Supporting Endpoint	Supporting Endpoint
Community composition as percentages of major taxonomic groups[c]	Supporting Endpoint	AEMP Variable
Densities of dominant invertebrates: midges (Chironomidae), bivalves (Pisidiidae), andamphipods (Amphipoda)	-	AEMP Variable

a) As presented in the EC EEM TGD (2012) and/or the MDMER (Government of Canada 2018).
b) As presented in the AEMP Design Plan (Golder 2016a).
c) Henceforth reported as relative density.
- = not applicable.

Total invertebrate density was calculated as the number of organisms per square metre (org/m^2) for each station. This calculation was based on the bottom area of the grab sampler (0.0232 m^2) multiplied by 5 grabs (i.e., 0.116 m^2) to represent the total area sampled by five grabs.

$$\frac{\text{number of organisms per replicate sample}}{\textit{(sampler area [0.0232 } m^2\textit{] } \times \textit{ number of subsamples [5])}}$$

Richness is the total number of taxa/station at the family level or the LTL. Richness provides an indication of the diversity of benthic invertebrates in an area; a higher richness value typically indicates a more healthy and balanced community.

For interpretation purposes, ranges in benthic invertebrate densities and LTL richness values were operationally defined as low/moderate/high, based on previous AEMP in northern lakes within Canada and information documented in associated annual reports (e.g., 2016 Diavik AEMP Annual Report [Golder 2017b], 2016 De Beers Gahcho Kue AEMP Annual Report [De Beers 2017c]). Observed density and richness values were categorized as follows:

- **low:** density less than 5,000 org/m²; LTL richness less than 10 taxa/station
- **moderate:** density ranging from 5,000 to 50,000 org/m²; LTL richness ranging from 10 to 40 taxa/station
- **high:** density greater than 50,000 org/m²; LTL richness greater than 40 taxa/station

When compared to other lake environments, the range of densities described above are relatively low considering some lake environments have densities greater than 100,000 individuals per square metre (Hynes 1970; Resh and Rosenberg 1984; Rosenberg and Resh 1993).

Simpson's Diversity Index (SDI) measures the proportional distribution of organisms in the community, taking into account taxonomic richness and how evenly the total density is distributed among these taxa. Certain conditions may favour one organism over another, resulting in the community being dominated by a few taxa, which is reflected in decreased diversity (Simpson 1949). The SDI values range between zero and one, where lower values indicate a less diverse community and higher values indicate a more diverse community. The SDI was calculated using the formula provided by Krebs (Krebs 1999):

$$SDI = 1 - \sum_{i=1}^{S} (p_i)^2$$

Where:

- SDI = Simpson's diversity index
- S = the total number of taxa
- p_i = the proportion of the i^{th} taxon

Simpson's Evenness Index (SEI) is a measure of how evenly the total invertebrate density is distributed among the taxa present at the station. The SEI is included along with the SDI to provide context as to whether taxonomic richness or the distribution of total density among taxa is driving the SDI values. The SEI is also expressed as a value between one and zero, with one representing high evenness (i.e., equal numbers of all taxa present in a sample) and zero representing low evenness (i.e., a high degree of dominance by one or a few organisms). The SEI values were calculated using the following formula (Smith and Wilson 1996):

$$SEI = 1/\sum_{i=1}^{S}(p_i)^2/S$$

Where:

- SEI = Simpson's evenness index
- S = the total number of taxa
- p_i = the proportion of the i^{th} taxon

The above variables are measures of total invertebrate density, taxonomic richness, and structural aspects of the community, but do not consider any quantitative information of the types of organism's present. Therefore, the Bray-Curtis Index (BCI; a dissimilarity index) was calculated to compare entire communities between reference and exposure areas. The BCI summarizes the overall difference in community structure between two stations (Environment Canada 2012). BCI values range between 0 and 1, whereby lower values indicate that the community in the exposure area is more similar to the reference community.

As recommended by Environment Canada (2012), the BCI was calculated following the method by Legendre and Legendre (1983), where the distance statistic is calculated as:

$$\text{B-C}=\frac{\sum_{i=1}^{n}|y_{i1}-y_{i2}|}{\sum_{i=1}^{n}(y_{i1}-y_{i2})}$$

Where:

- B-C = Bray-Curtis distance between sites 1 and 2
- y_{i1} = count for taxon i at site 1
- y_{i2} = count for taxon i at site 2
- n = total number of taxa present at the two sites

BCI values have historically been calculated by comparing the benthic community of each station to the median reference area community (using pooled reference area data). This method (henceforth abbreviated to BCI-EEM in this assessment) is recommended by the EEM TGD (Environment Canada 2012). Hubert et al. (2011) pointed out that using the reference median value as the basis for calculating Bray-Curtis distance values results in frequently finding effects where none exist, referred to as a Type I error (false positive). To correctly calculate Bray-Curtis distance, Huebert et al. (2011) recommended that pairwise, among-area comparisons of individual reference and exposure stations be conducted to generate Bray-Curtis distance values for statistical comparisons.

Therefore, Bray-Curtis distance values were also calculated using the pairwise comparisons method (henceforth abbreviated to BCI-PW in this assessment). For replicated reference areas, this meant that each reference area station was compared to all stations in the other reference area and a mean BCI was calculated (to estimate background among-area variation). Similarly, each exposure station was compared to all reference stations and a mean BCI was calculated. To meet the Cycle 1 EEM requirements and those of the AEMP Study Design, Bray-Curtis distances for all years were calculated using both pairwise and the EEM methods.

9.2.4.4 Normal Range

The magnitude of effect on benthic invertebrate communities was evaluated by comparing benthic variables (i.e., density, richness, SDI, SEI, BCI and densities of dominant taxa) in the Near-field area to background values. Background values (or normal ranges) were calculated using reference area data (i.e., from MEL-03, MEL-04 and MEL-05 [also referred to as Reference areas 1, 2, and 3]) collected from 2015 to 2018, and baseline data collected from the Near-field and Mid-field areas in 2015.

The 2016 Near-field data were excluded from normal range calculations because the 2017 AEMP Annual Report (Golder 2018c) suggested that benthic communities in the Near-field area may have been influenced by STP effluent discharged to a rock-bed channel that emptied into Meliadine Lake near the exploration camp. The benthic invertebrate response pattern in the Near-field area was consistent with mild nutrient enrichment. A review of nutrient loadings from the STP discharge in Section 2.7 identified an approximate doubling of TP loadings, in 2016 relative to 2015, from the STP discharge to the rockbed channel close to the Meliadine Lake Near-field area. The increase in TP loadings from the STP discharge represents a confounding factor that prohibits the 2016 Near-field data (collected under baseline conditions for the Mine effluent discharge) from being included in the dataset used to calculate the normal ranges for BIC variables in Meliadine Lake.

Methods for defining the BIC normal range follow the methods of Barrett et al. (2015) and are consistent with the approach used for defining normal ranges for other AEMP components (i.e., water quality, sediment quality, and plankton). A summary of the methods considered in this assessment is provided below:

- When background data were normally distributed, the normal range was estimated as the 80% prediction interval (PI) of the dataset. Normality was assessed using the Shapiro Wilk test, using $\alpha = 0.05$ to indicate a significant departure from normality.
- When the background data were not normally distributed, but normality could be achieved after Box-Cox transformation (Box and Cox 1964), the normal range was calculated on the Box-Cox transformed data and the upper and lower bound of the normal ranges were back-transformed.

- If neither the untransformed data or Box-Cox transformed datasets were normally distributed, the normal range boundaries were defined as the 10th and 90th percentile of the baseline data. In cases where the percentile method was used, a dataset of 1,000 samples was randomly generated from the normal range dataset and the 10th and 90th percentile were calculated from this distribution of 1,000 samples to estimate the normal range.

It should be noted that the normal ranges provided in this report are considered provisional during the initial monitoring years under the AEMP due to the limited sample sizes used in the calculations. The normal range is intended to estimate the range of natural spatial and temporal variability, and the more reference data incorporated into the calculation, the more accurate the estimate becomes. These normal ranges may be redefined in future reports to allow for the inclusion of additional appropriate monitoring data as they become available.

Normal ranges determined for the 2018 AEMP are summarized in Table 9.2-3.

Table 9.2-3: Normal Ranges for Benthic Invertebrate Community Variables

Benthic Invertebrate Community Variable	Unit	Normal Range	
		Lower Limit	Upper Limit
Total invertebrate density	org/m²	128	1,938
Total taxonomic richness[a]	taxa/station	8	18
Simpson's diversity index[a]	-	0.69	0.88
Simpson's evenness index[a]	-	0.25	0.64
BCI-EEM (compared to REF1 median)[a]	-	0.28	0.73
BCI-EEM (compared to REF3 median)[a]	-	0.21	0.70
BCI-PW[a]	-	0.47	0.74
Chironomid density	org/m²	123	1,588
Bivalve density	org/m²	43	365

a) Normal Ranges were calculated for benthic invertebrate variables at the lowest taxonomic level.

org/m² = organisms per square metre; BCI = Bray-Curtis Index; EEM = Environmental Effects Monitoring; PW = pairwise; REF = reference area.

9.2.4.5 Statistical Analysis

9.2.4.5.1 General Approach

Statistical analysis was used to evaluate whether there were statistically significant differences in EEM BIC endpoints between the Near-field area and Reference Area 1 in 2018. Thus, to evaluate if the Mine effluent discharge had an effect on the BIC in the Near-field area. For the 2018 AEMP data analysis, a similar statistical approach was used to evaluate differences among sampling areas, but it was applied to all areas sampled to meet the objectives of the AEMP Design Plan (Golder 2016a). Univariate statistical tests (i.e., Spearman correlations, ANOVA, pairwise comparisons) were performed using SYSTAT Version 13.2 (Systat Software Inc., Chicago, IL).

Summary statistics (i.e., arithmetic mean, median, minimum, maximum, standard deviation standard error, and sample size) for each BIC endpoint and AEMP variable were calculated and summarized by sampling area.

9.2.4.5.2 Cycle 1 EEM

Prior to undertaking univariate statistical tests for each BIC EEM endpoint, data were screened for outliers and potential data entry errors, as described in Appendix 9C. Based on the screening results presented in Appendix 9C, no outliers were identified in the dataset used for the Cycle 1 EEM statistical analysis.

To compare BIC endpoint values between the Near-field area and Reference Area 1, an ANOVA test was completed in SYSTAT Version 13.1 (Systat Inc. 2017). Prior to analysis, benthic data were checked for statistical assumptions (i.e., normality, homoscedasticity; Zar 1999). If data did not meet the statistical assumptions, the equivalent non-parametric test (e.g., Kruskal-Wallis with post-hoc Conover-Inman) was conducted. Data were considered significantly different at α = 0.1, as recommended by EC (2012).

No data transformations were necessary to satisfy the requirement of normality for ANOVA, with the exception of SEI, where data were ranked prior to analysis. The SEI values are derived variables with unusual statistical properties and, in general, their sampling distributions are unknown (Rosenberg and Resh 1993). Transformation of SEI to rank order (i.e., all stations are pooled for the purpose of ranking) relaxes the assumption of normality and allows the use of ANOVA.

Magnitude of difference between the Near-field area and Reference Area 1 was calculated using untransformed data, according to the following equation:

$$\frac{x_e - x_r}{x_r} \times 100$$

Where:

- x_e = the exposure area mean;
- x_r = the reference area mean

The critical effect size (CES) was calculated as ±2 standard deviations, as recommended by the EEM TGD (Environment Canada 2012), expressed as a percentage of the reference mean. The magnitude of difference was also expressed as the number of reference area standard deviations, as per the following equation:

$$\frac{x_e - x_r}{\sigma_r}$$

Where:

- x_e = the exposure area mean;
- x_r = the reference area mean;
- σ_r = the reference area standard deviation

A statistically significant difference in an effect endpoint was only considered biologically significant if the magnitude of effect exceeded the CES. For a study design with five replicate stations per area, Environment Canada (2012) recommends that α and β be set equally at 0.10 to allow a CES equal to ±2 SD from the reference area mean (refer to Table 9-7 of the EEM TGD [Environment Canada 2002]). Using this design, power was set a priori at 0.90.

For non-significant results, *post-hoc* power analyses were run to determine power required to detect a biologically meaningful effect (i.e., with a magnitude equal to the CES).

9.2.4.5.3 2018 AEMP

Prior to undertaking univariate statistical testing for each benthic AEMP variable, data were screened for outliers, as described in Appendix 9C. Based on the screening results presented in Appendix 9C, no outliers were identified in the dataset used for the AEMP statistical analysis. Reference area data were pooled from Reference Area 1 (MEL-03) and Reference Area 3 (MEL-05) for inclusion in statistical testing for each benthic variable with the Near-field area and the Mid-field area.

To compare benthic variables among AEMP areas within Meliadine Lake, an ANOVA test was completed in SYSTAT Version 13.1 (Systat Inc. 2017). Prior to analysis, benthic data were checked for statistical assumptions (i.e., normality, homoscedasticity; Zar 1999). If data did not meet the statistical assumptions, the equivalent non-parametric test (e.g., Kruskal-Wallis with post-hoc Conover-Inman) was conducted. No data transformations were necessary to satisfy the requirement of normality for ANOVA, with the exception of SEI, where data were ranked prior to analysis by ANOVA (as described in Section 9.2.4.5.2).

Where the overall ANOVA was found to be significant at $\alpha = 0.1$, pairwise comparisons (i.e., planned contrasts) were made to compare the exposure areas to the pooled reference areas for all benthic variables. Specifically, the following pairwise comparisons were made:

- Near-field area versus pooled reference areas
- Mid-field area versus pooled reference areas
- Reference Area 1 versus Reference Area 3

Data were considered significantly different at $\alpha = 0.1$

9.2.4.5.4 Multivariate Analysis

Benthic invertebrate community structure was analyzed using the non-parametric ordination method of non-metric multidimensional scaling (nMDS; Clarke 1993). nMDS is a multivariate method based on the BCI. The nMDS data were scaled in Primer, version 7 for Windows (PRIMER E Ltd., Quest Research 2017; Clarke and Gorley 2016). Lowest taxonomic level (LTL)BIC data were log (x+1) transformed, to improve separation of the data among stations on the nMDS plots and to reduce weighting of the analysis by the most abundant taxa.

A Bray-Curtis resemblance matrix was generated, and the nMDS procedure was applied to this matrix. Using rank order information, nMDS determined the relative positions of stations in two dimensions based on community composition. Goodness-of-fit was determined by examining the Shepard diagrams as well as the stress value, which was calculated from the deviations in the Shepard diagrams. Lower stress values (i.e., less than 0.10) indicate less deviation and a greater goodness-of-fit, higher stress values (i.e., greater than 0.20) must be interpreted with caution and often higher dimensions (i.e., 3-D) are needed to describe the data (Clarke 1993). Points that fall close together on the nMDS ordination plot represent samples with similar community composition; points that are far apart from each other represent samples with dissimilar community composition. A similarity profile (SIMPROF) test was also carried out on the ordination data to identify meaningful clusters of important taxa (i.e., those taxa that behave in a coherent manner across areas) and to prevent over-interpretation of the nMDS plots (Clarke et al. 2014). These SIMPROF clusters were superimposed on the MDS plots.

An overall one-way analysis of similarities (ANOSIM) test was carried out on the Bray-Curtis resemblance matrix to confirm interpretation of the separation of the points on the MDS ordination plot, and to investigate whether differences in community composition observed in the nMDS ordination plots were significant. In addition, an area-level pair-wise ANOSIM was carried out to compare Near-field and Mid-field areas to the reference areas

sampled in 2018. Pair-wise comparisons of the Near-field area between 2015, 2016 and 2018 (all pairwise combinations) were also conducted. A Bray-Curtis resemblance matrix was generated to test differences among areas contrasted with differences among stations within each area (Clarke et al. 2014) or differences among years contrasted with differences among stations within each year in the Near-field area.

An R-statistic ranging from 0 to 1 was produced by the analysis; a strong difference in community composition was indicated by R = 1 and no difference between communities was indicated by R = 0. Significance of the R statistic was achieved when a *P*-value of >0.05 was reported, based on the five replicate stations per area.

9.2.4.5.5 Evaluation of the Effects of Habitat Variation

Spearman rank correlation analysis was used to test the strength of relationships between key habitat variables (i.e., water depth, TOC, particle size, sediment metal concentrations above sediment quality guidelines, nutrient [TN and TP] concentrations in lake water) and benthic community variables (i.e., total density, richness, diversity, evenness, densities of dominant invertebrate groups). This analysis was completed on pooled data from all stations sampled in 2018 to identify environmental factors that could potentially confound the study design (e.g., habitat variables), or account for the variation observed in the benthic community (e.g., metals in sediments). Critical values for significance were determined from Siegel and Castellan (1988). Spearman rank correlation coefficients were calculated using SYSTAT Version 13.2 (Systat Software Inc., Chicago, IL). Thresholds for statistical significance of $P < 0.05$, $P < 0.01$, and $P < 0.001$ were applied to identify significance of correlations.

Results of the correlation analysis were used to evaluate whether variation in key habitat variables may represent confounding factors that could potentially influence statistical comparisons between sampling areas. This analysis also provided a preliminary evaluation of relationships between key sediment and water quality variables, and benthic community variables. Where a correlation between environmental variables and benthic community variables was moderately to highly statistically significant (i.e., P<0.01), scatter plots were produced to support the interpretation of the significant correlations.

9.2.4.5.6 Characterization of Within-Station Variability

To characterize within-station variability, discrete samples were collected from station MEL-05-04 in Reference Area 3. At this station, five subsamples (discrete grab samples) were collected and sorted separately from one another. Total abundance and richness values for the five subsamples were visually assessed and percent standard error of the mean (%SE)[8] of the five subsamples was calculated for each variable. A%SE value of <20% is considered to be indicative of within-station variability typical for benthic invertebrate communities based on Elliott (1971).

[8] SE expressed as the percentage of the mean.

9.3 Quality Assurance/Quality Control

The QA/QC practices applied during this study and detailed results of the QC analyses are provided in Appendix 9C). QA components of the program included the use of trained personnel and a qualified taxonomist; QC components included assessments of sampler fullness and sorting efficiency. A summary of key QC results and observations is provided below.

- Grab sampler fullness was evaluated and only data from samples where grabs were at least 40% full were included in the BIC assessment as per Golder's Specific Work Instructions (Golder 2018e unpublished file information).
- Sorting efficiency was considered acceptable for the two samples tested (96% and 100%) (Environment Canada 2012).
- Samples were sorted in their entirety by the taxonomic laboratory, so an assessment of subsampling efficiency was not required for 2018.
- Due to an equipment malfunction, samples from stations MEL-01-01, MEL-01-06, MEL-01-08, and MEL-01-09 were not field sieved at the time of collection. Samples were preserved and kept cold and sieved at the earliest opportunity. These samples were replenished with the addition of new preservative prior to submission to the taxonomist.

Based on this assessment, the benthic invertebrate monitoring data are considered adequate to meet the requirements of the Cycle 1 EEM Study Design (Golder 2017a) and the AEMP Design Plan (Golder 2016a).

9.4 Results and Discussion

9.4.1 Habitat Characteristics

Habitat characteristics for 2018 are summarized in Table 9.4-1, Figure 9.4-1 and Figure 9.4-2. Detailed habitat data and summary statistics are presented in Appendix 9A, Table 9A-1 and the *Sediment Reconnaissance Survey Summary* (Appendix 9A). Water and sediment quality data collected in conjunction with the BIC monitoring program, for the Water Quality and Sediment Quality AEMP components, are provided in Section 6.0 and 8.0.

The following observations were noted from a review of the 2018 habitat data:

- Mean water depth ranged from 7.2 m (Reference Area 1) to 9.0 m (Reference Area 3) for benthic stations sampled in 2018 (Table 9.4-1). Thus, the reference areas encapsulated the depth range sampled in 2018, with the exposure areas captured within the reference area depth range.
- Average bottom water temperatures represented typical seasonal values for subarctic lakes in Northern Canada, between 8.8°C (Reference Area 3) and 10.7°C (Mid-field area).
- Average DO values indicated the overlying water at all stations in 2018 was well oxygenated and above the CWQG-PAL for minimum DO concentration.
- Average pH values indicated that the overlying water was slightly alkaline and values were within the CWQG-PAL range of 6.5 to 9.0 (Table 9.4-1).

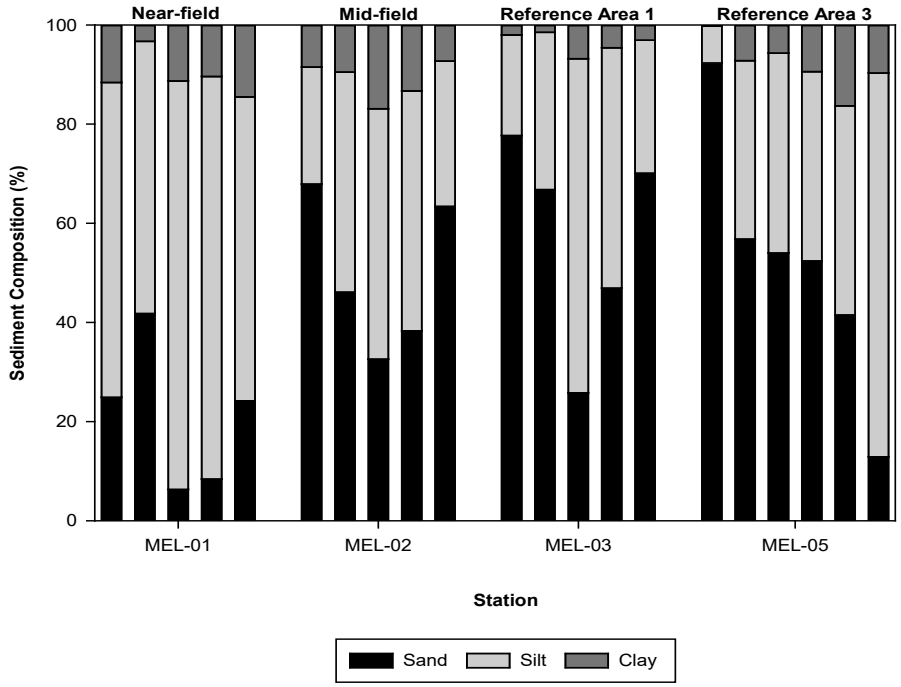
- Mean specific conductivity values in the overlying water were characteristically low, reflective of subarctic environments. Slightly higher mean specific conductivity values were recorded in the Near-field area compared to other areas sampled (i.e., Near-field >Mid-field >Reference Area 3 >Reference Area 1), but they were within a factor of 1.2 of measurements at Reference Area 1 (Table 9.4-1).
- Sediment TOC showed some variability among sampling areas (i.e., Near-field >Mid-field >Reference Area 3 >Reference Area 1), with the Mid-field area TOC higher than Reference Area 1 TOC by a factor of 1.8. The Near-field TOC was most comparable to Reference Area 1 values and the Mid-field TOC was most comparable to Reference Area 3 values Table 9.4-1).
- Sediments sampled from the Near-field area had a higher proportion of fines (i.e., silt + clay) and less sand compared to the Mid-field and reference areas (Figure 9.4-1). These particle size results are consistent with those reported by Golder (2018a) for the 2015 and 2016 AEMP baseline sampling events (Figure 9.4-2). Thus, as discussed by Golder (2018a), spatial differences in particle size distribution between the Near-field area and other sampling areas have the potential to confound the ability of the AEMP and EEM study comparisons made to evaluate whether benthic invertebrate communities were impacted by the Mine effluent discharge in 2018. This is evaluated further in Sections 9.4.2 and 9.4.4.

Table 9.4-1: Summary of Habitat Variables for Meliadine Lake in 2018

Area	Water Depth	In-situ Water Quality				Sediment Total Organic Carbon	Sediment Particle Size			
		Water Temperature	Dissolved Oxygen	pH	Specific Conductivity		Sand	Silt	Clay	Fines (Silt + Clay)
	(m)	(ºC)	(mg/L)	-	(µS/cm)	(%)	(%)	(%)	(%)	(%)
Near-field	7.8	10.6	12.0	8.6	86.8	4.5	21.1	68.7	10.2	78.9
Mid-field	8.1	10.7	10.8	8.3	77.0	6.7	49.7	39.2	11.1	50.4
Reference 1	7.2	9.4	12.0	8.5	72.1	3.7	57.5	38.9	3.6	42.6
Reference 3	9.0	8.8	11.9	8.2	75.9	5.9	50.6	41.1	10.3	49.4

Note: Mean values are presented for each sampling area.

µS/cm = microSiemens per centimetre.



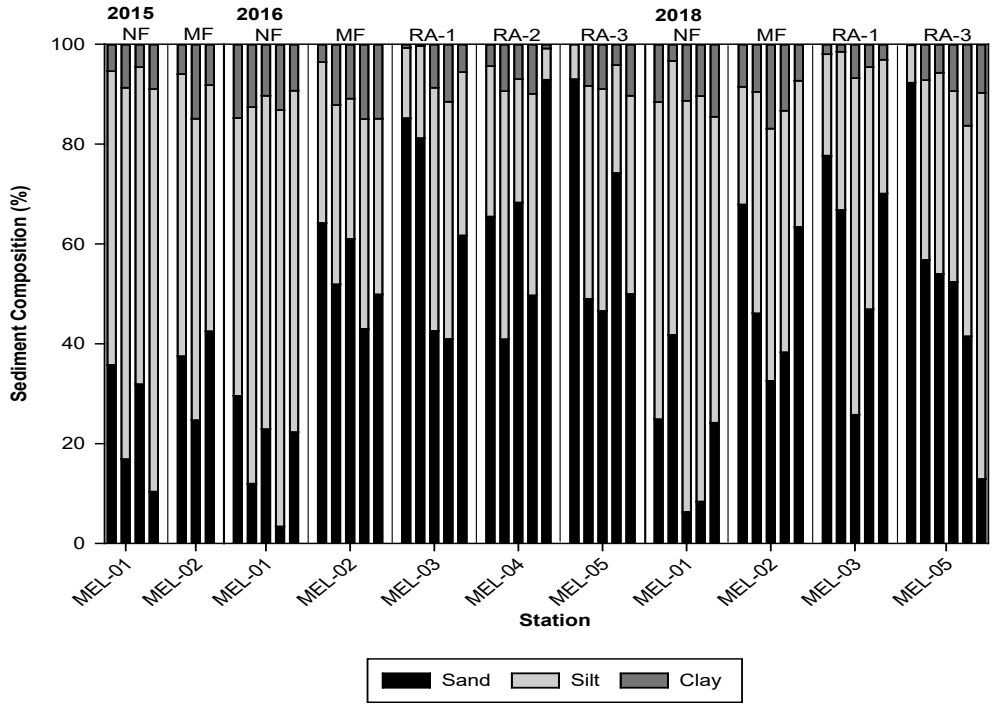


Figure 9.4-1: Sediment Particle Size Comparison for Meliadine Lake, 2018

NF = Near-field area; MF = Mid-field area; RA-1 = Reference Area 1; RA-3 = Reference Area 3

9.4.2 Benthic Invertebrate Community

Raw benthic invertebrate abundance data, presence/absence data, and a summary of BIC variables calculated from the raw taxonomy data are presented in Appendix 9D, Tables 9D-2 to 9D-4. A summary of the results from the analysis of the EEM and AEMP benthic community variables is provided below.

9.4.2.1 EEM

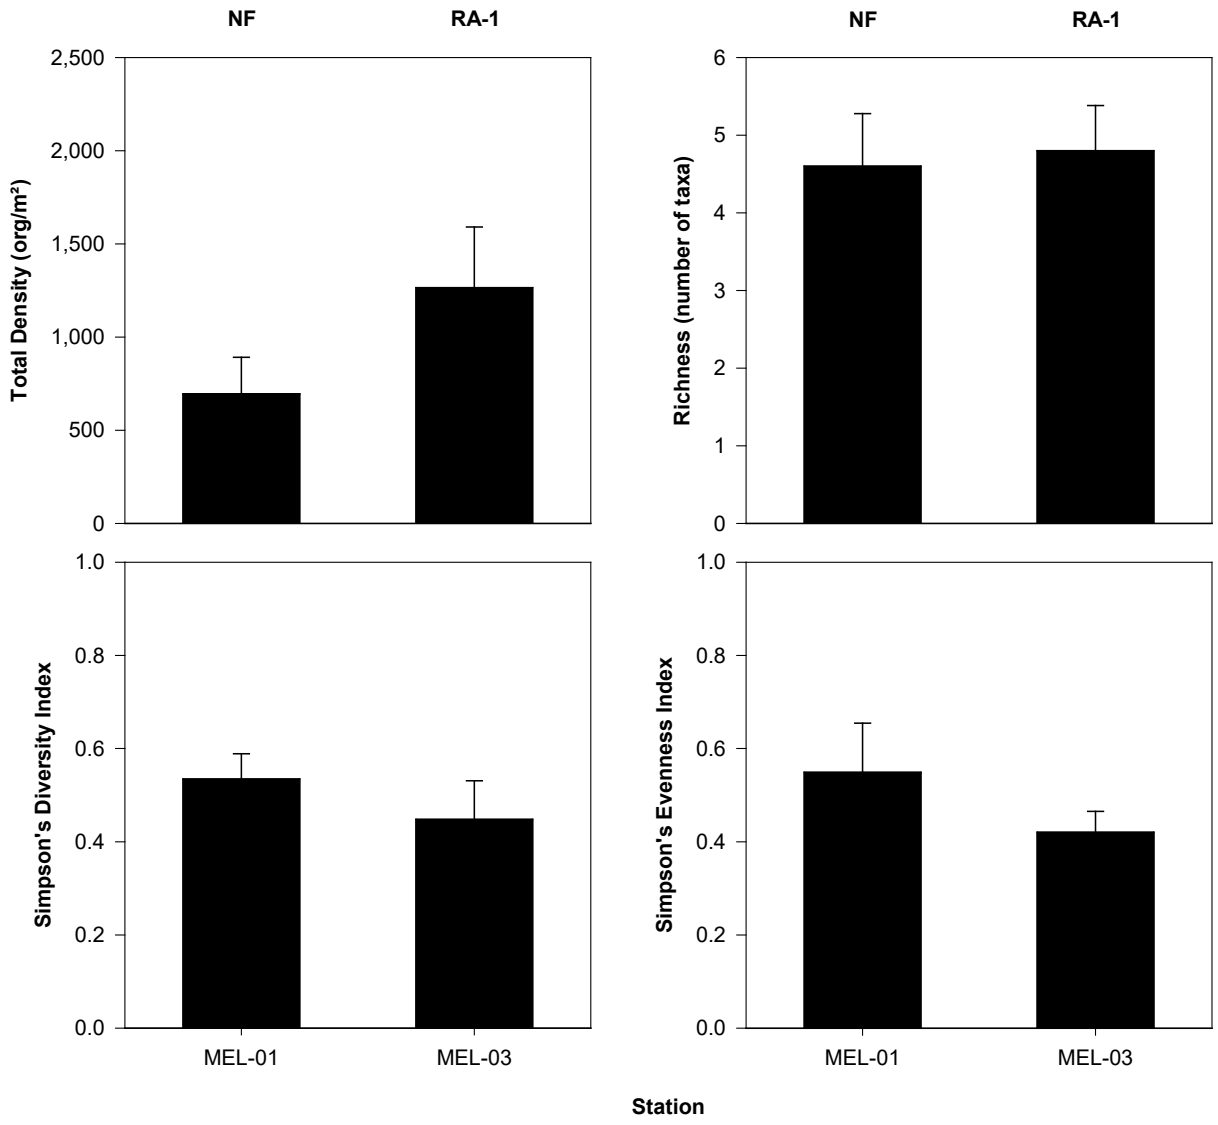
Total density (<2,000 organisms/m^2 per station) and richness (<6 taxa per station) were low in all areas sampled in Meliadine Lake in 2018. Moderate to low SDI, SEI and BCI values were also calculated in 2018.

EEM BIC comparisons were conducted at the family level to detect differences between the Near-field area and Reference Area 1, in relation to potential impacts from the Mine effluent discharge, as per the EEM TGD (Environment Canada 2012). These EEM results are presented below in Figure 9.4-3 and Figure 9.4-4, with statistical results presented in Table 9.4-2. No statistical differences were found between the Near-field area and Reference Area 1 for the EEM or supporting endpoints (i.e., P>0.1). The CES for these endpoints were not exceeded in 2018 (Table 9.4-2). Thus, for all endpoints included in the Cycle 1 EEM assessment, there were no significant effects of the Mine effluent discharge on benthic invertebrate communities in the Near-field area.

Table 9.4-2: Results of Statistical Tests Comparing EEM Sampling Areas, 2018

Variable	Overall Comparison (NF vs Ref 1)[a]	Direction	Magnitude[b] (SD)	Magnitude[c] (%)	CES (±2SD)[d] (%)	Exceeded CES
Total invertebrate density	0.173	NF<REF1	-0.8	-44.9	170	No
Total taxonomic richness (FL)	0.829	NF=REF1	0.0	0.0	50	No
Simpson's diversity index (FL)	0.408	NF>REF1	0.5	21.1	84	No
Simpson's evenness index (FL)	0.275	NF>REF1	1.3	30.7	41	No
BCI-EEM (compared to REF1 median) (FL)	0.490	NF>REF1	0.4	57.1	161	No
BCI-EEM (compared to REF3 median) (FL)	0.534	NF>REF1	0.4	28.1	145	No
BCI-PW (FL)	0.655	NF>REF1	0.3	10.9	84	No
Chironomidae Density	0.224	NF<REF1	-0.7	-51.9	155	No
Pisidiidae Density	0.862	NF>REF1	0.1	7.6	148	No

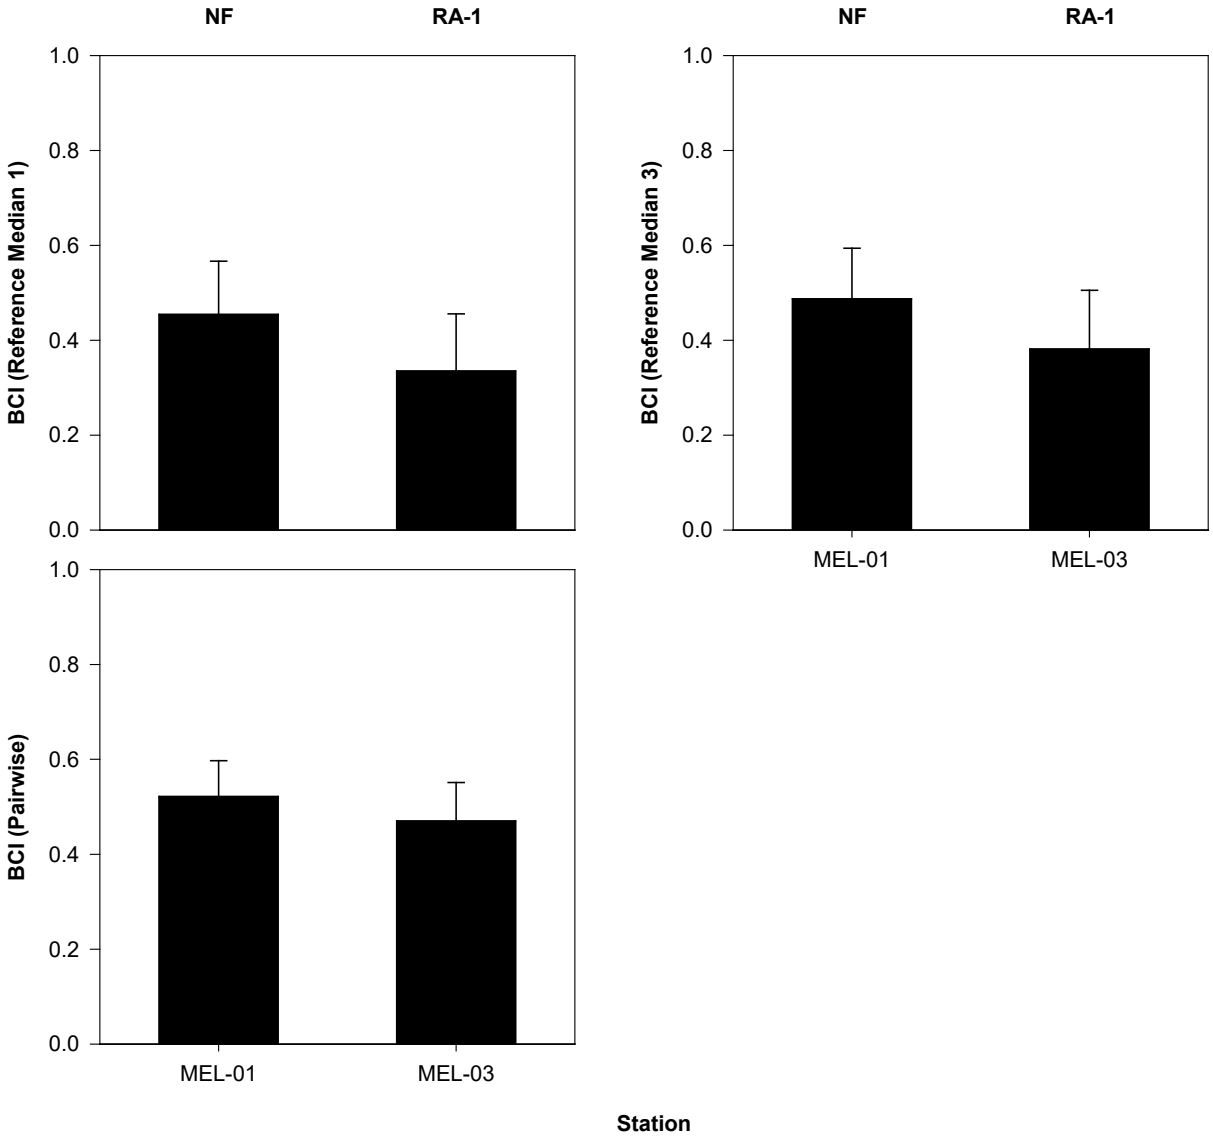
Note: Statistical testing was completed using family taxonomic levels for the benthic invertebrate variables.



a) Significance evaluated at $\alpha = 0.1$

b) Magnitude was calculated as the difference in number of reference area standard deviations (i.e., NF mean compared to Ref 1 mean).

c) Magnitude was calculated as percent difference between the sampling area means (i.e., NF mean compared to Ref 1 mean).



d) Effect size was calculated as ±2 standard deviations, expressed as a percentage of the reference area mean.

BCI = Bray-Curtis Index; EEM = Environmental Effects Monitoring; PW = pairwise; FL = family level; CES = critical effect size; NF = Near-field area; REF = Reference area; SD = standard deviation.

NF = Near-field; MF = Mid-field; RA-1 = Reference Area 1; RA-3 = Reference Area 3. Error bars represent 1 standard error.

Figure 9.4-3: Mean Benthic Invertebrate Endpoints and Supporting Variables in EEM Sampling Areas, 2018

NF = Near-field; MF = Mid-field RA-1 = Reference Area 1; RA-3 = Reference Area 3. Error bars represent 1 standard error.
Note: BCI (Reference Median 1 and Reference Median 3) were calculated using BCI EEM method.

Figure 9.4-4: Mean Bray Curtis Index Values in EEM Sampling Areas, 2018

9.4.2.1.1 *Post-hoc* Power Analysis

As demonstrated in the EEM TGD (Environment Canada 2012), a basic control/impact study design requires five samples per area to attain a power of 0.90 to detect an effect size of ±2SD. *Post-hoc* power analysis specific to the Cycle 1 EEM statistical analysis for the Mine, indicated there was insufficient power for family level richness and family level evenness, despite the sample size of five. In order to detect an effect of ±2SD (based on the Reference Area 1 data) at 90% power, six samples per area would be required for the richness and 16 samples per area for evenness. For evenness, the Cycle 1 EEM dataset had a non-normal data distribution and therefore required rank order transformation prior to analysis, which many have influenced the *post-hoc* power analysis for this endpoint.

9.4.2.2 AEMP

The 2018 AEMP compared data collected from Near-and Mid-field exposure areas to two reference areas through statistical and visual comparisons, to evaluate potential changes in benthic invertebrate communities due to changes in water and sediment quality.

9.4.2.2.1 Spatial Comparisons between Sampling Areas in 2018

Total Density and Richness

In 2018 total invertebrate density and richness in Meliadine Lake were considered to be within the low-density category for subarctic lakes (i.e., <5,000 org/m^2) consistent with the 2015 and 2016 baseline years (Appendix 9D, Table 9D-4, Golder 2018c). In 2018, each sampling area demonstrated a moderate range of variability in density among replicate sampling stations, which was comparable among sampling areas:

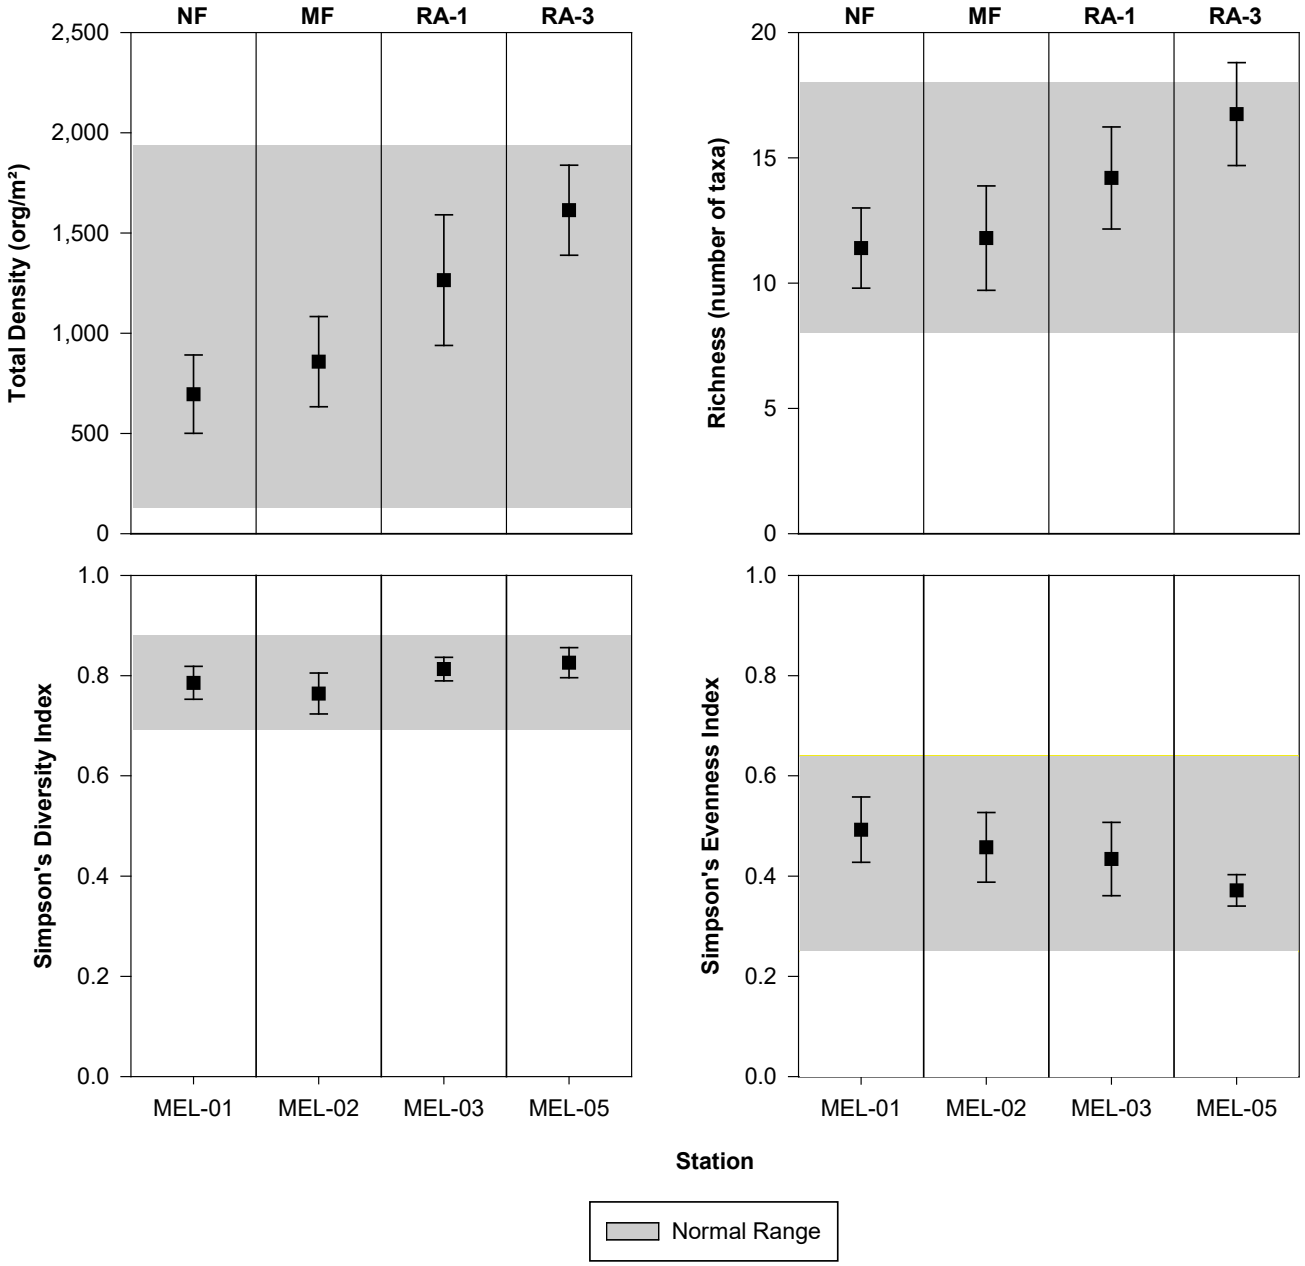
- **Exposure Areas**: Near-field area (233 to 1,234 org/m^2), Mid-field area (276 to 1,448 org/m^2)
- **Reference areas**: Reference Area 1 (241 to 1,241 org/m^2), Reference Area 3 (1,078 to 2,172 org/m^2)[9]

At the LTL, total richness values were similar among the Near-field area (8 to 16 taxa), Mid-field area (7 to 18 taxa), and Reference Area 1 (7 to 18 taxa). Richness was higher in Reference Area 3 (13 to 22 taxa).

A significant difference was found between sampling areas for total invertebrate density but not for total richness (Table 9.4-3). *Post-hoc* comparisons found density to be significantly different between the Near-field area and the pooled reference areas. No significant differences in density were detected between the Mid-field area and the pooled reference areas, or between the two reference areas.

Table 9.4-3: Results of Statistical Tests Comparing AEMP Sampling Areas, 2018

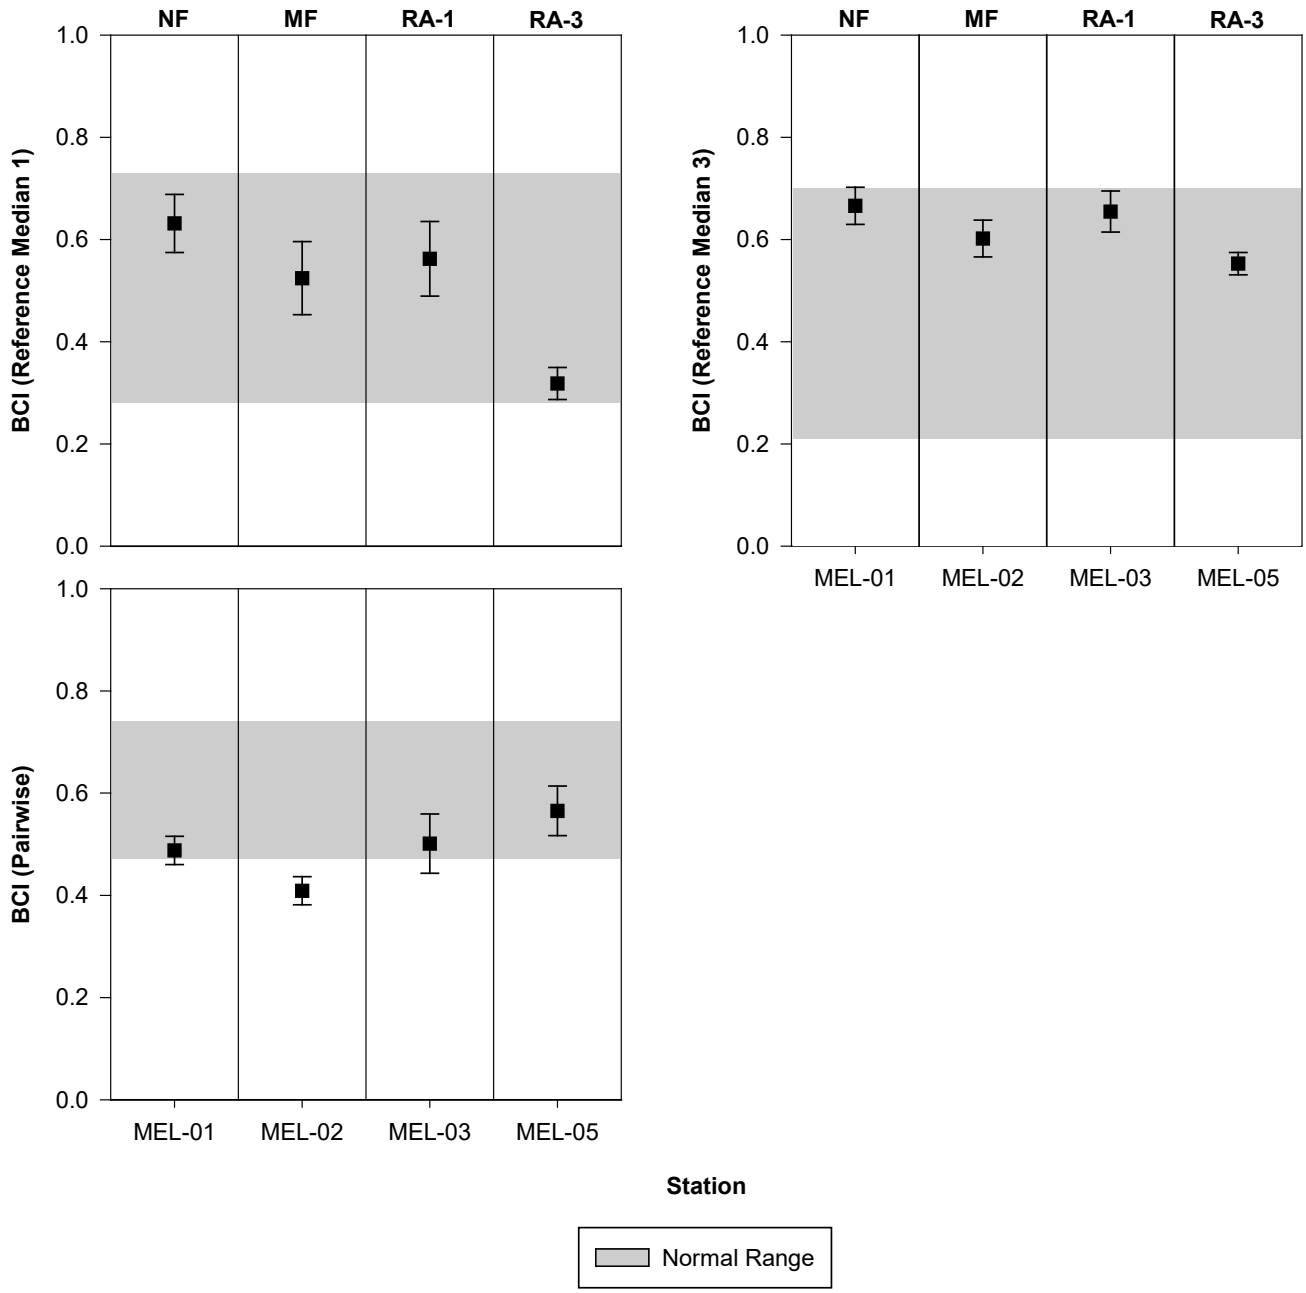
Variable	Statistical Test	Overall Comparison[(a)]	NF vs (REF 1 & REF 3)[(a)]	MF vs (REF 1 & REF 3)[(a)]	REF 1 vs REF 3[(a)]
Total invertebrate density	ANOVA	**0.095**	**<0.001**	0.689	0.122
Total taxonomic richness (LTL)	ANOVA	0.258	-	-	-
Simpson's diversity index (LTL)	ANOVA	0.925	-	-	-
Simpson's evenness index (LTL)	ANOVA	0.451	-	-	-
BC-EEM (compared to REF1 median) (LTL)	ANOVA	0.128	-	-	-
BC-EEM (compared to REF3 median) (LTL)	ANOVA	**0.026**	**<0.001**	0.353	0.439
BCI-PW (LTL)	ANOVA	0.158	-	-	-
Chironomidae density	ANOVA	0.142	-	-	-
Pisidiidae density	ANOVA	0.969	-	-	-



Note: Statistical testing was completed using lowest taxonomic level for the benthic invertebrate variables. No data transformations were required prior to analysis to satisfy parametric test assumptions. Significant differences are **bolded**; significance was evaluated at P <0.10.

a) Significance of planned contrasts was evaluated at P <0.1.

BCI = Bray-Curtis index; EEM = Environmental Effects Monitoring; PW = pairwise; NF = Near-field area; MF = Mid-field area; REF = reference area; REF 1 & REF 3 = pooled reference areas; - = not applicable, ANOVA = analysis of variance; LTL = lowest taxonomic level.



[9] Post removal of the station MEL05-05 from the dataset for Reference Area 3.

All exposure and reference area means were within the normal range for total density and taxonomic richness, although Reference Area 3 mean density and richness values approached the upper limit of the normal range (Figure 9.4-5). Spatial trends showed that the Near-field area and to a lesser degree the Mid-field area had lower mean densities and richness in 2018 compared to Reference Area 1 or Reference Area 3 (Figure 9.4-5). As described above, only density in the Near-field area was significantly lower than the pooled reference area density.

NF = Near-field; MF = Mid-field; RA-1 = Reference Area 1; RA-3 = Reference Area 3. Error bars represent 1 standard error.

Figure 9.4-5: Mean Total Benthic Invertebrate Density, Richness, Simpson's Diversity Index and Simpson's Evenness Index in Meliadine Lake, 2018

NF = Near-field; MF = Mid-field RA-1 = Reference Area 1; RA-3 = Reference Area 3. Error bars represent 1 standard error.
Note: BCI (Reference Median 1 and Reference Median 3) were calculated using BCI EEM method.

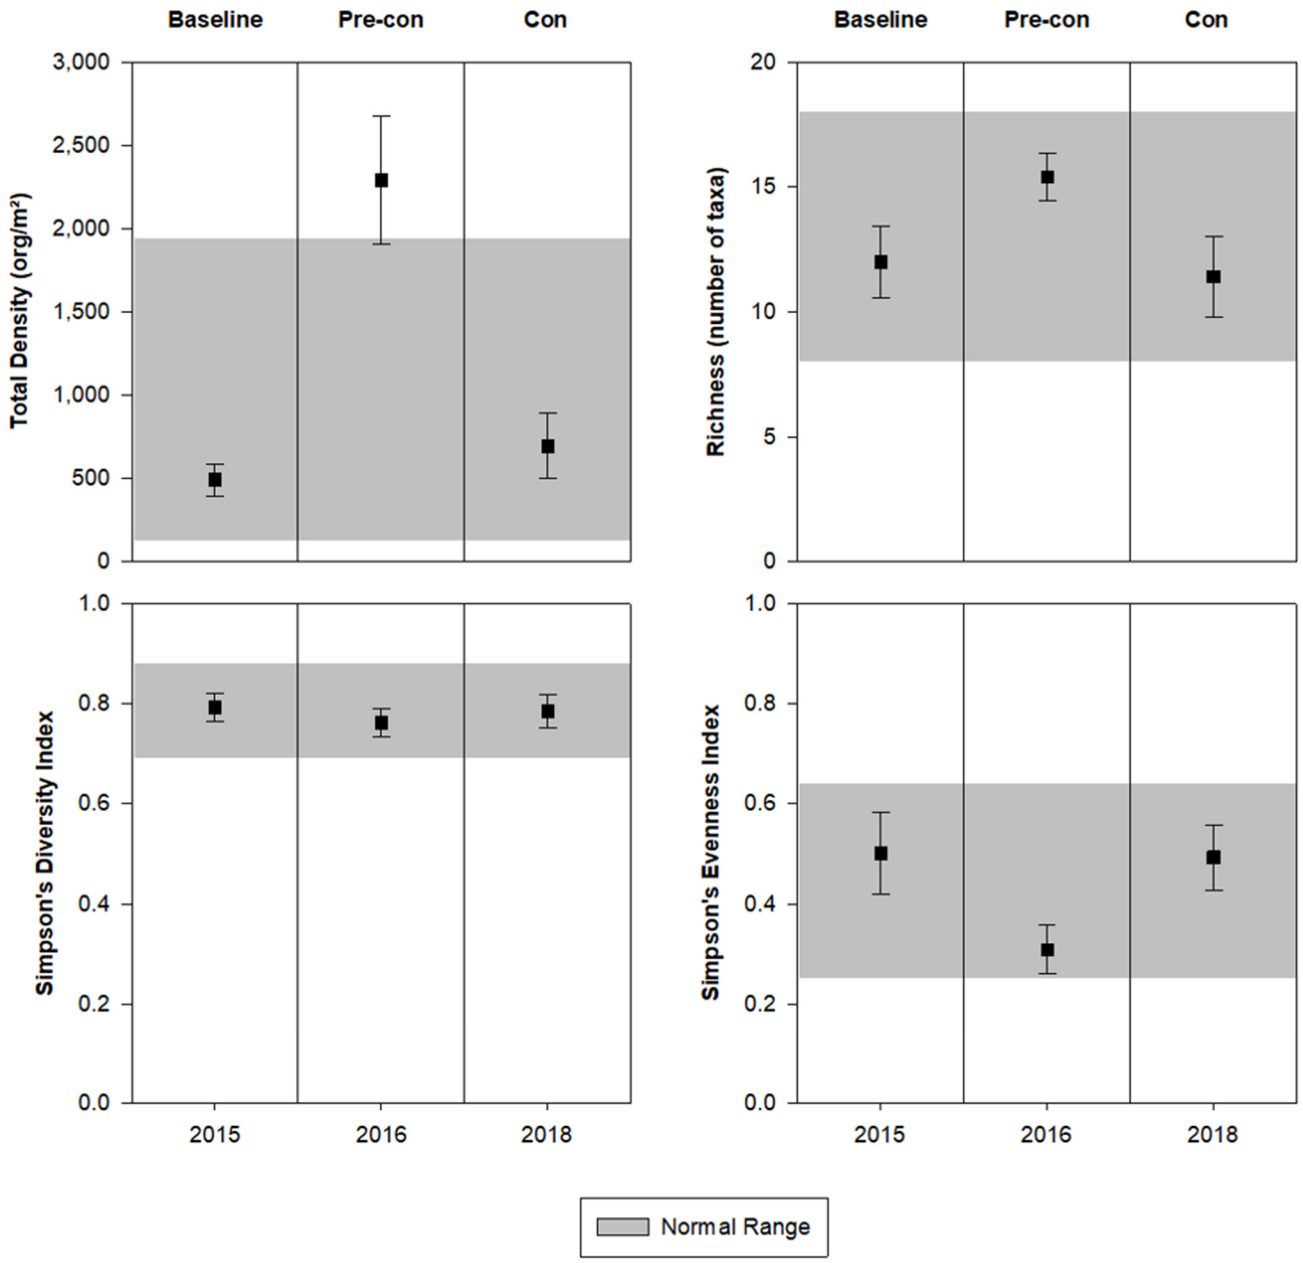
Figure 9.4-6: Mean Bray-Curtis Index Values for the Benthic Invertebrate Community in Meliadine Lake, 2018

Diversity, Evenness, and Bray Curtis Indices

In 2018, SDI and SEI calculated at the LTL, showed no statistically significant differences between sampling areas (Table 9.4-3). Diversity (SDI LTL) was consistent across all areas sampled with low variability among replicates (Figure 9.4-5). Evenness (SEI LTL) showed a decreasing trend with distance from the diffuser (i.e. Near-field >Mid-field >Ref 1 >Ref 3) (Figure 9.4-5), but all SDI and SEI values were within the bounds of the normal range.

Consistent with Golder (2018a), 2018 BCI values were calculated using the LTL data for the AEMP analysis, following both EEM and pairwise methods. The following observations were noted from the results from both calculation methods presented in Table 9.4-3 and Figure 9.4-6.

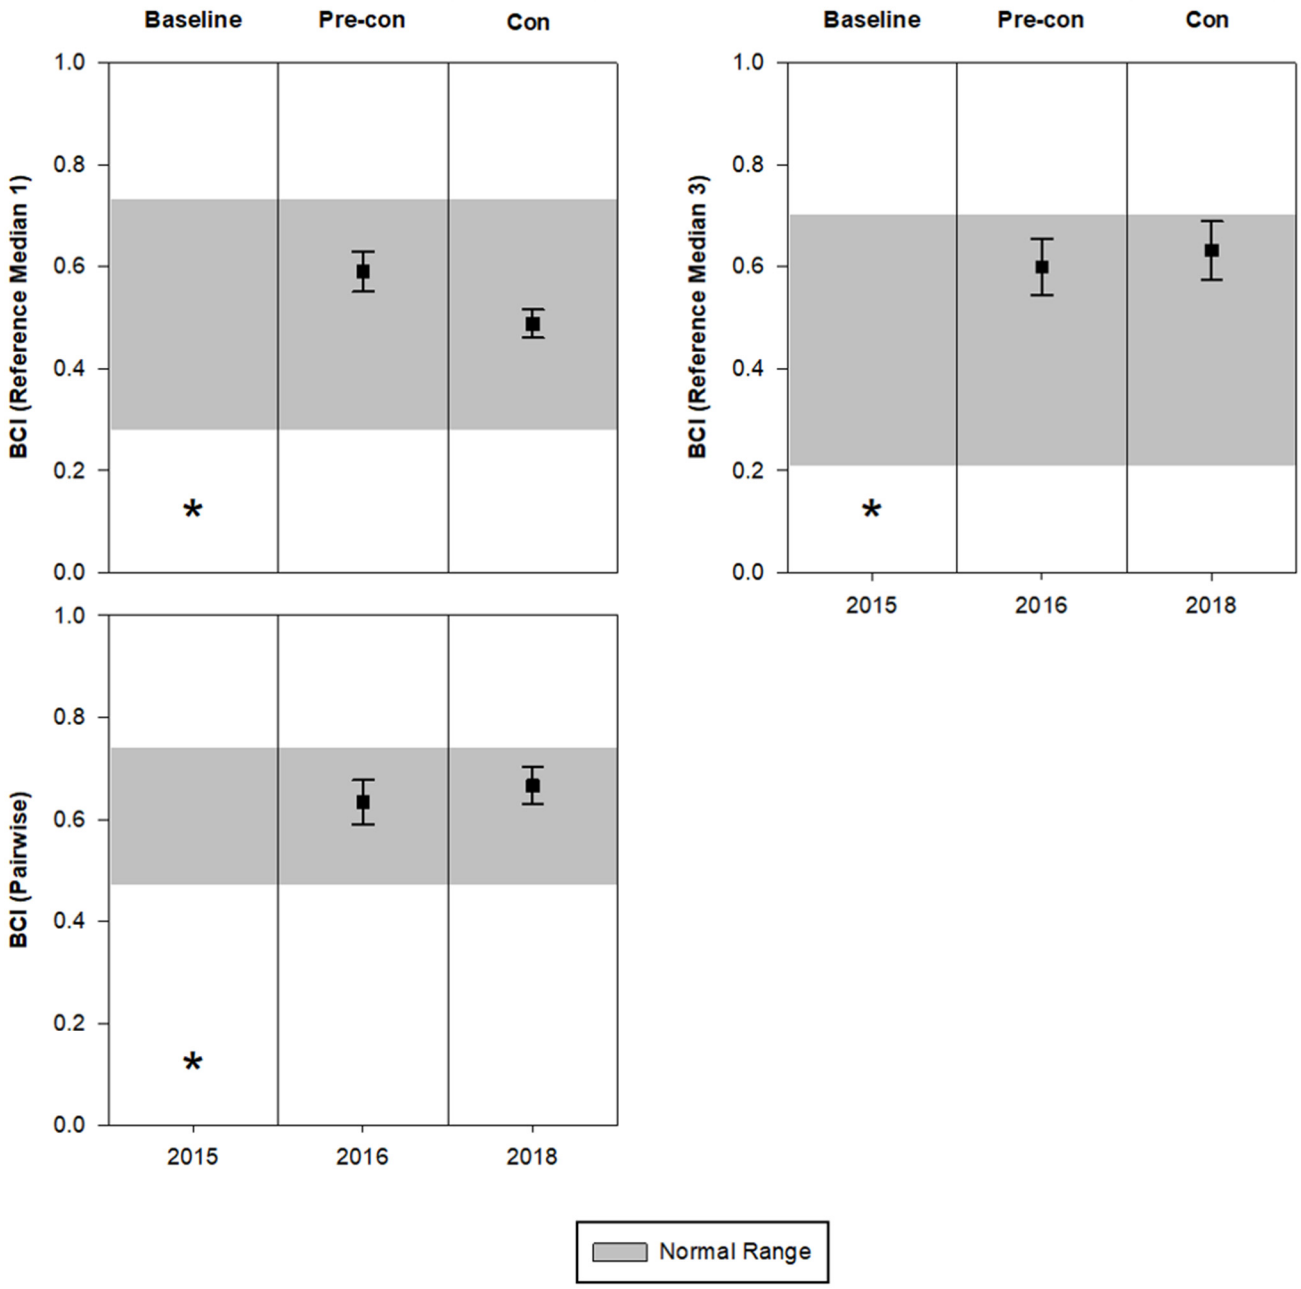
- BCI values were low to moderately dissimilar for all sampling areas using both calculation methods. The Near-field BCI values were most dissimilar compared the Reference Area 3 values using the EEM method and more aligned with those calculated for Reference Area 1. Using the BCI-EEM method (Reference Area 3 median value) a significant difference was detected in the overall ANOVA and for the *post-hoc* comparison, when the Near-field area was compared to the pooled reference areas (Table 9.4-3). Conversely, the ANOVA for the BCI EEM method (Reference Area 1 median value) did not identify a significant difference in the overall comparison.
- Using the BCI-PW method, the Reference Area 3 was the most dissimilar and the Mid-field area the least dissimilar. Again, BCI values calculated for the Near-field area most closely aligned with Reference Area 1. The ANOVA for the BCI PW method did not identify a significant difference in the overall comparison ($P>0.1$).
- All mean BCI values calculated using both the EEM and the pairwise methods were within the bounds of the normal range. The exception was the Mid-field area BCI calculated using the PW method.



9.4.2.2.2 Temporal Comparisons: Baseline (2015, 2016) and Operation (2018) Years

Temporal trends in biological variables in the Near-field area for the monitoring years 2015, 2016 and 2018 were visually evaluated to evaluate differences in the BIC over time (Figure 9.4-7 and Figure 9.4-8; Figure 9C-2 to 9C-4, Appendix C). The time period evaluated extended from the AEMP baseline into the first year of the Mine effluent discharge.

The following observations were noted with respect to temporal trends:



- Total invertebrate density in the Near-field area increased between 2015 and 2016 by almost a factor of two, followed by a decrease from 2016 to 2018 to values similar to those observed in 2015 during pre-construction. Increases in density and richness in 2016 to values above the normal range for density, but within the normal range for richness, potentially reflected a mild nutrient enrichment response, as reported by Golder (2018a). As described in Section 2.6, phosphorus loadings to the Near-field area peaked in 2016 as a result of the exploration camp STP discharge at the MEL-07 and then decreased substantially by 2018. By the 2018 AEMP sampling event, the STP discharge had ceased and the centralized Mine effluent discharge had commenced at the MEL-14 location.
- Unlike density and richness, diversity and evenness values in the Near-field area were reasonably comparable among years, although evenness appeared to decrease in 2016 compared to 2015 and 2018.

- No reference areas were sampled during 2015, therefore no BCI calculations were possible (Figure 9.4-8). BCI values in the Near-field area for both methods (EEM median and PW) showed low to moderate BCI values, with no visual differences among the years, and all years were within the normal range (Figure 9.4-8).

Pre-con = Pre-construction; Con = Construction. Error bars represent 1 standard error.

Figure 9.4-7: Mean Total Benthic Invertebrate Density, Richness, Simpson's Diversity Index and Simpson's Evenness Index in the Near-field Area, 2015, 2016 and 2018

Note: BCI (Reference Median 1 and Reference Median 3) were calculated using BCI EEM method.
Pre-con = Pre-construction; Con = Construction; * = no 2015 reference area data collected, not applicable. Error bars represent 1 standard error; BCI = Bray-Curtis Index.

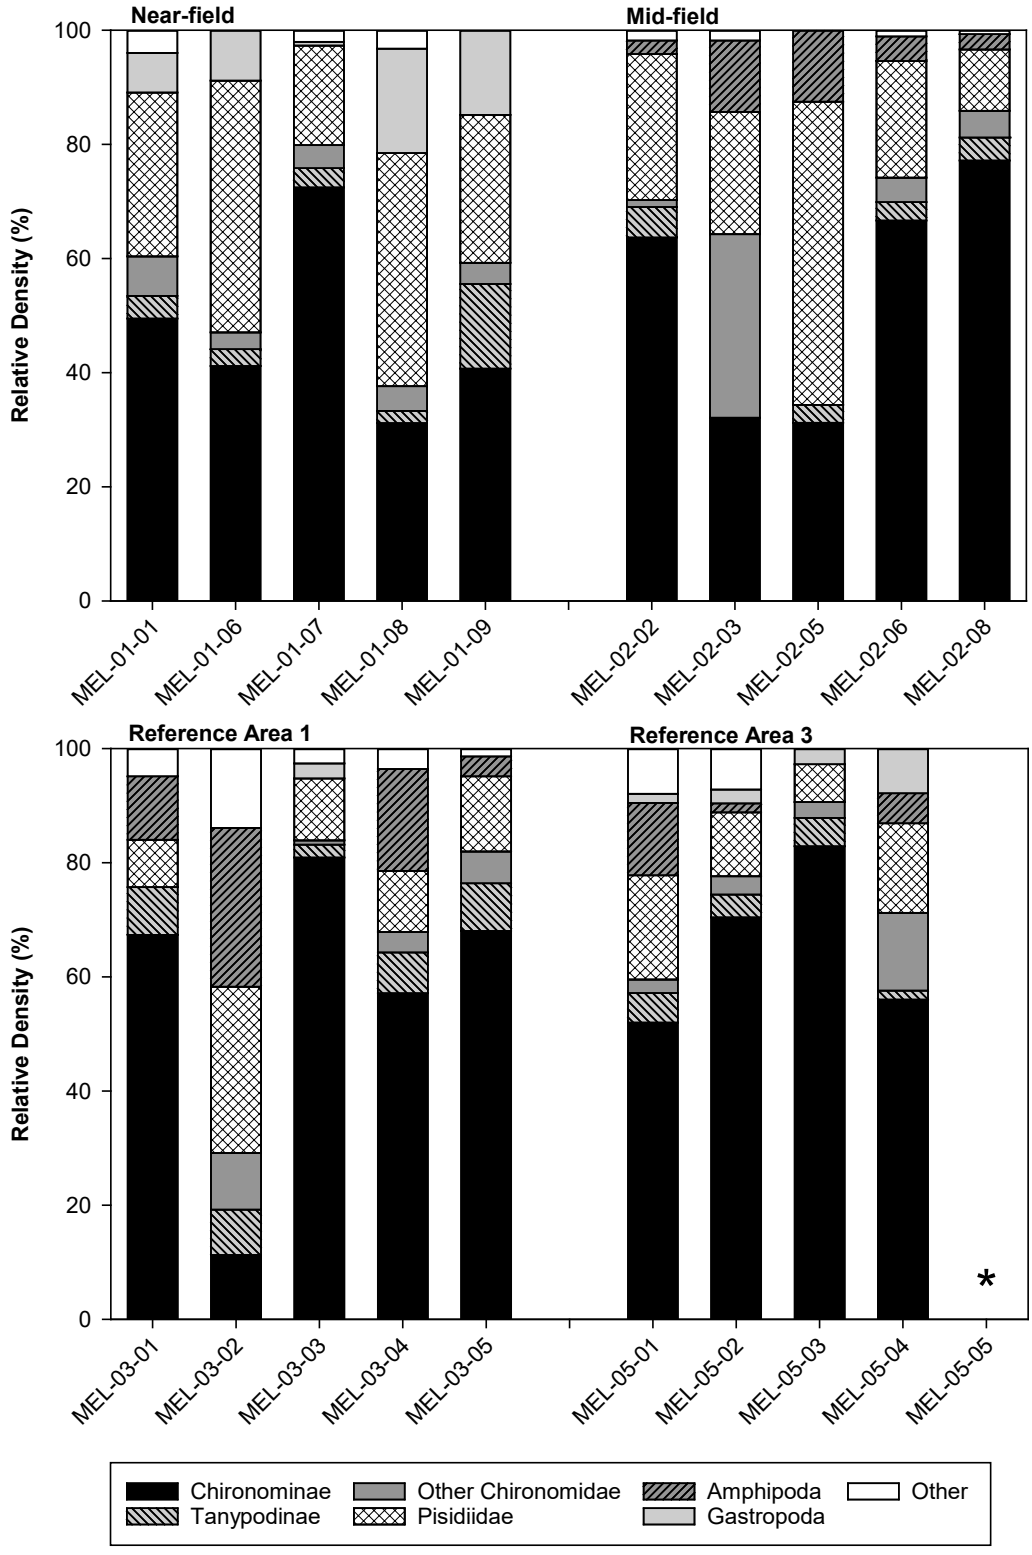
Figure 9.4-8: Mean Bray-Curtis Index Values for the Benthic Invertebrate Community in the Near-field Area, 2015, 2016 and 2018

9.4.2.2.3 Community Composition and Densities of Dominant Invertebrates

Benthic invertebrate taxa present at all stations consisted of 12 common subarctic taxa from the taxonomic groups Pisidiidae, Hydracarina and Chironomidae subfamilies: Chironominae, Tanypodinae, Orthocladiinae, and Prodiamesinae (Appendix 9D, Table 9D-3).

Dominant benthic invertebrates previously documented in Meliadine Lake include insects, including midges (Chironomidae), fingernail clams (Pisidiidae), valve snails (Valvatidae), and amphipods (shrimp-like crustaceans) (Golder 2018c). Overall, BIC structure in Meliadine Lake is consistent with other subarctic lakes (Golder 2017b and DeBeers 2018). Oliver (1968) stated that dipterans typically contribute one third to one half of total number of species in subarctic benthic invertebrate communities. This is consistent with the 2018 Meliadine Lake AEMP results, which reported Chironomidae to be the dominant group across all sampling stations accounting for 70% of the total density. Pisidiidae (18%) was the subdominant group, followed by Amphipoda (5%) as the third most numerous group (Figure 9.4-9).

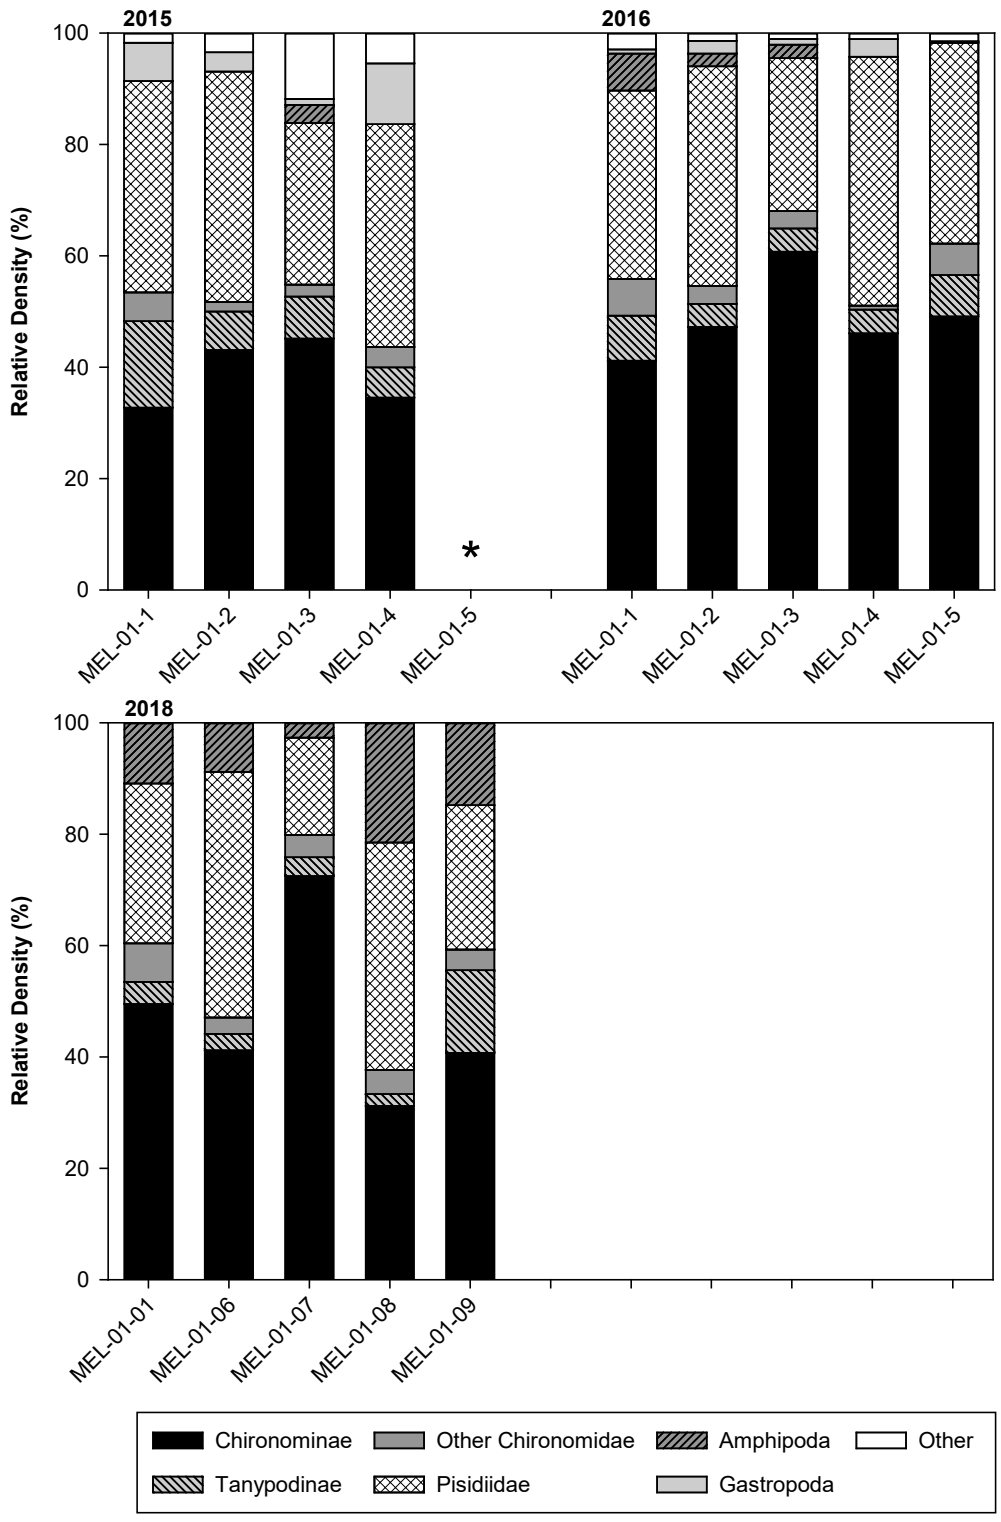
The Near-field area benthic community showed a wide range in Chironomidae relative density among stations: from 38% (MEL-01-08) to 80% (MEL-01-07) (Figure 9.4-9 and Figure 9.4-10). Pisidiidae was the subdominant group at all stations in the Near-field area, ranging from 17% (MEL01-07) to 44% (MEL01-06), with the exception of MEL-01-08 where co-dominance was observed between Chironomidae and Pisidiidae. Gastropods were present at all stations at low densities (<18%), likely reflective of their affinity for fine (silt/clay) substrates, which is supported by general preferences of genus present (*Valvata*) (Thorp and Covich 2001). Amphipoda were absent from Near-field area stations.



Mid-field area relative densities showed comparable chironomid dominance in comparison to the Near-field area, that ranged from 34% (MEL02-05) to 86% (MEL02-08), and reasonably comparable Pisidiidae densities that ranged from 11% (MEL02-08) to 53% at MEL02-05 (Figure 9.4-9). Amphipods were the third most abundant group, with relative abundance ranging from 2% to 13%. No gastropods were captured in the Mid-field area.

The relative density of Chironomidae in Reference Area 1 was proportionally high at all stations (60% to 84%), with the exception of MEL03-02, where Chironomidae density was 29% in 2018 (Figure 9.4-9). Mean Chironomidae relative density was similar to the Mid-field area (68%). Community composition at MEL03-02 was evenly proportioned among Chironomidae, Pisidiidae and Amphipoda (approximately 29% each). Gastropoda were absent at all stations with the exception of MEL03-03.

Mean Chironomidae relative density in Reference Area 3 in 2018 ranged from 60% (MEL05-01) to 91% (MEL05-04) (Figure 9.4-9). Pisidiidae contributed less than 18% of the relative density in Reference Area 3. Amphipods and gastropods constituted <5% to the community composition. One station (MEL05-05) was removed from the data analyses as it contained only one individual of Chironomidae (*Microtendipes* sp.).



In 2018, there were minor visual differences between the relative densities of dominant taxa (i.e., Chironomidae, Pisidiidae) in the Near-field area compared to Reference Area 1 (Figure 9.4-9). Chironomidae relative density increased with increasing distance from the CP1 diffuser, likely due to higher proportions of sand in the Reference areas. Pisidiidae showed the opposite relationship and the highest proportions were observed in the Near-field and Mid-field areas, likely associated with the presence of finer sediments. Similarly, gastropods were observed in the Near-field area at higher proportions than in any other areas.

Chironomidae density increased with increasing distance from the Near-field area in 2018, while Pisidiidae density was similar in all sampling areas (Fogure 9-12). Visual differences were apparent among years for Chironomidae and Pisidiidae densities: both had higher densities in 2016 compared to both 2015 and 2018 (Figure 9.4-12). However, densities of these groups in 2018 were not visually different from the baseline year of 2015.

9.4.2.2.4 Multivariate Analysis

The nMDS run on the 2018 BIC dataset produced a two-dimensional configuration with an overall stress value of 0.12, indicating a good level of fit to the original dataset (Figure 9.4-13). Community structure within all areas was moderately similar (i.e., within the 60% similarity ellipse), although some separation was observed between the Near-field area (MEL01) and the other sampling areas. The similarity was higher (i.e., within the 70% similarity ellipse) between the Mid-field area (MEL02) and the reference areas (MEL03 and MEL05). Similar to the univariate results, the Near-field area showed significant differences from the Mid-field area (i.e., $P = 0.032$) and Reference Area 1 (i.e., $P = 0.024$) (Table 9.4-4). No other significant differences were observed.

The configuration for the Near-field area BIC ordination run on 2015 and 2018 data had an overall stress value of 0.06, indicating a good level of fit to the original dataset (Figure 9.4-14). Community structure within the Near-field area showed separation of the 2016 Near-field area stations from the 2015 and 2018 Near-field area stations, reflective of the univariate results. Although all years were within low to moderate similarity ellipses (i.e. 40% and 50%) the pair-wise ANOSIM results comparing years were significantly different (i.e., R>0.5, $P = 0.08$) for all pairwise comparisons of years (Table 9.4-5). These results suggest a potentially high degree of variation in BIC structure among years in Meliadine Lake.

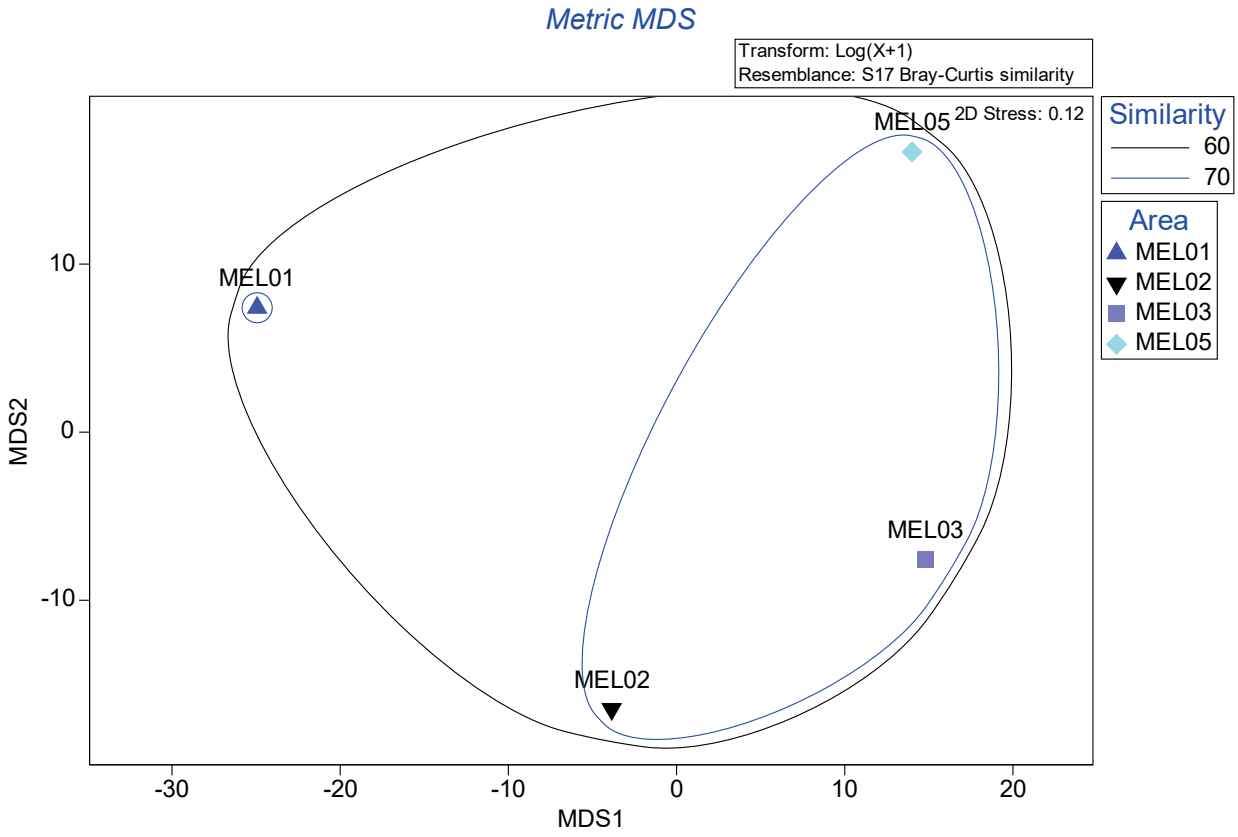

Figure 9.4-13: Ordination Plot of the Benthic Invertebrate Community for Meliadine Lake, 2018

Table 9.4-4: Benthic Invertebrate Community ANOSIM Results, 2018

Area	Area Comparisons	
	R statistic	*P*-value
Near-field Area (MEL01) vs Mid-field Area (MEL-02)	0.488	**0.032**
Near-field Area (MEL01) vs Reference Area 1 (MEL-03)	0.381	**0.024**
Near-field Area (MEL01) vs Reference Area 3 (MEL-05)	0.325	0.063
Mid-field Area (MEL-02) vs Reference Area 1 (MEL-03)	0	0.714
Mid-field Area (MEL-02) vs Reference Area 3 (MEL-05)	0.284	0.056
Reference Area 1 (MEL-03) vs Reference Area 3 (MEL-05)	0.036	0.349

Note: Comparisons are significant at $P < 0.05$. **Bolded** values indicate significance.
P = probability.

Table 9.4-5: Benthic Invertebrate Community ANOSIM Results, 2015, 2016 and 2018

Years	Near-field Comparisons	
	R statistic	*P*-value
2015 vs 2016	0.848	**0.008**
2015 vs 2018	0.640	**0.008**
2016 vs 2018	0.594	**0.008**

Significant differences are **bolded**. Significance was evaluated at $P<0.05$.

9.4.2.2.5 Effect of Variation in Habitat, and Sediment and Water Quality on the Benthic Invertebrate Community

The potential for variation in physical habitat, sediment quality and water quality parameters to contribute to spatial and temporal variability in community structure among stations in Meliadine Lake was evaluated using Spearman rank correlation analysis. Variables included in the correlation analysis were sediment particle size parameters, sediment TOC, concentrations of metals present in Meliadine Lake sediments above CCME sediment quality guidelines (i.e., arsenic, chromium, copper), waterborne concentrations of total phosphorus and nitrogen, and water depth.

Results of the Spearman correlations are provided in Table 9.4-6. Scatter-plots of habitat and community variables were not completed for 2018 because the significant relationships identified were below the moderate to high significance criterion, where further interpretation beyond the analysis presented here would be warranted.

The following significant correlations were identified from the results of the correlation analysis summarized in Table 9.4-6.

- Total invertebrate and Chironomidae densities were significantly negatively correlated with total phosphorus in water. However, these relationships were weak and inconsistent with a nutrient enrichment response (i.e., densities decreased with increased waterborne phosphorus).
- LTL richness was positively correlated with sand and negatively correlated with silt, clay, and sediment arsenic and chromium concentrations. Sediment metal concentrations were shown to increase with decreasing grain size in Section 8.0, with higher metal concentrations reported in finer sediments. This association was observed under baseline conditions; therefore, it is possible that resident biota in finer sediments have adapted to metal concentrations in those sediments.
- LTL evenness was negatively correlated with depth, suggesting that deeper stations had a less even distribution of taxa. This relationship is not unexpected in lakes under background conditions.

Overall, results of this analysis do not indicate that habitat variation, or variation in sediment or water quality, have an overriding influence on the BIC in Meliadine Lake. However, this is a coarse-level analysis, and due to high variation in data close to the analytical DL for TP (i.e., the most likely limiting nutrient in Meliadine Lake), correlation results for nutrient relationships may not be representative. Potential biological effects related to Mine-related variation in nutrient concentrations in Meliadine Lake are discussed further in Section 11.0 (Plankton Targeted Study).

Table 9.4-6: Spearman Rank Correlations between Benthic Invertebrate Community Variables and Selected Habitat Variables for Meliadine Lake, 2018

Benthic Community Variable	Spearman Correlation Coefficient									
	TOC	Sand	Silt	Clay	As in Sediment	Cr in Sediment	Cu in Sediment	TP in Water	TN in Water	Water Depth
Total density	-0.063	0.347	-0.386	-0.300	-0.439	-0.318	-0.296	**-0.544***	-0.022	0.395
Richness, FL	-0.386	0.267	-0.232	-0.402	-0.256	-0.149	-0.256	-0.154	-0.076	0.124
Richness, LTL	-0.296	**0.545***	**-0.566***	**-0.468***	**-0.502***	**-0.520***	-0.449	-0.407	-0.227	0.220
SDI, LTL	-0.384	0.321	-0.363	-0.210	-0.262	-0.170	-0.373	0.059	-0.037	-0.194
SEI, LTL	-0.126	-0.123	0.116	0.201	0.154	0.219	0.010	0.358	0.280	**-0.568***
Chironomidae density	0.109	0.310	-0.363	-0.216	-0.425	-0.248	-0.210	**-0.481***	-0.033	0.431
Pisidiidae density	-0.276	0.043	-0.083	-0.078	-0.105	-0.007	-0.075	0.308	-0.065	0.237

Note: Significant correlation coefficients are **bolded.**

TP = total phosphorus; TN = total nitrogen; FL = family level; LTL = lowest taxonomic level; * = $P<0.05$, ** = $P<0.01$, *** = $P<0.001$, $n = 19$.

9.4.2.2.6 Characterization of Within-Station Variability

The results of the characterization of within-station variability are presented in Appendix 9C, Table 9C-1 and Figure 9C-1.

The %SE value for richness was <20% for subsamples taken at station MEL-05-04, which indicates that the observed within-station variability was within the range expected for benthic invertebrate communities due to natural variability (Elliott 1971). As expected, total abundance was more variable than richness. The %SE for abundance at MEL-05-04 (24.7%) was slightly above 20% but was comparable or lower than within-station variability reported for other subarctic lakes in Northern Canada (e.g., DDMI 2007), including those previously reported for Meliadine Lake (Golder 2018c) and the level of within-station variability is considered acceptable. The assessment of 2018 within-station variability at station MEL-05-04 supports the continued compositing of five grab samples per replicate station for the EEM and AEMP programs at the Meliadine Mine. As per the AEMP Design Plan (Golder 2016a), samples for BIC analysis will therefore continue to be collected as a combination of composite samples (five grabs per station), along with individual subsamples (i.e., discrete samples) at one station to continue to evaluate within-station variation.

9.5 Summary

9.5.1 EEM

The BIC survey for the Cycle 1 EEM study was undertaken in August 2018 to evaluate if the Mine effluent discharge had an effect on benthic communities in Meliadine Lake. Benthic invertebrate community structure in the Near-field area exposed to the MEL-14 effluent discharge was compared to community structure in Reference Area 1 located within Meliadine Lake. Determination of an effect was based on statistical analysis of family-level benthic community effect endpoints and review of supporting endpoints, as recommended by EC (2012). Sediment physical characteristics and in situ water quality were evaluated to facilitate interpretation of benthic invertebrate data collected in fall 2018. The main findings of the 2018 EEM benthic survey are summarized below:

- No statistically significant differences were identified between the Near-field area and Reference Area 1 for the EEM effect endpoints and supporting endpoints evaluated in the Cycle 1 EEM study. The CESs for these endpoints were not exceeded.
- Total density was lower in the Near-field area compared to Reference Area 1, but both areas had similar family level taxa richness. Comparisons between the Near-field area and Reference Area 1 showed higher diversity, evenness, and Bray-Curtis dissimilarity in the Near-field area. Differences in these endpoints between the two sampling areas likely reflect pre-discharge differences in habitat, particularly differences in sediment substrate composition identified in Section 8.

Meliadine Lake benthic invertebrate communities were reflective of typical subarctic communities and were characterized by low densities and low to moderate family-level richness. Communities were dominated by the family Chironomidae, with Pisidiidae being subdominant. Gastropods were observed in the Near-field area at higher proportions compared to other areas, and amphipods were only present outside of the Near-field area, which likely reflects differences in habitat between the Near-field area and other sampling areas, reflecting taxon-specific habitat preferences.

9.5.2 AEMP

The objective of the BIC component of the AEMP was to evaluate whether treated Mine effluent has the potential to cause short or long-term effects on benthic invertebrate communities, due to changes in water or sediment quality in Meliadine Lake. This objective was addressed by comparing 2018 benthic invertebrate communities sampled in Near-field and Mid-field areas to two within-lake Reference areas. Benthic invertebrate AEMP variables were calculated at the LTL for all areas, and then compared among areas. In addition, the AEMP assessment also evaluated temporal changes in benthic community variables within the Near-field area for the monitoring years 2015, 2016 and 2018. This time period extended from the AEMP baseline into the first year of the Mine effluent discharge. Multivariate analysis was also run to investigate differences in community structure among sampling areas.

The main findings of the 2018 AEMP benthic invertebrate component are summarized below in point form to support the subsequent response to the AEMP key question:

- Significant differences were detected between the Near-field area and the pooled reference areas in 2018 for total invertebrate density and BCI (EEM method relative to Reference 3 median), in that the Near-field area had significantly lower density and BCI values compared to the pooled reference areas. There were no significant differences in richness, SDI, SEI or BCI (pairwise method or EEM method relative to Reference 1 median) between benthic communities from exposure and reference areas in 2018 based on LTL data.
- Multivariate analysis also found the Near-field area to be significantly different from the Mid-field area and the two Reference areas in 2018, although the benthic communities in these areas did show some overlap (60% similarity in community composition).
- In general, a limited number of significant correlations were identified between benthic community and habitat variables and they were generally weak. Despite some differences in sediment substrate type and chemistry among sampling areas, a significant correlation between total density and sediment parameters was not identified in 2018. Richness was significantly positively correlated with sand content and negatively correlated with silt, clay, and sediment arsenic and chromium concentrations. However, richness was not significantly different between the AEMP sampling areas.
- Normal ranges were developed for BIC variables using representative data from the 2015, 2016 and 2018 AEMP sampling programs. All mean 2018 AEMP variables for both exposure and reference areas sampled in Meliadine Lake were within their respective normal ranges, with the exception of BCI calculated using the pairwise method, where the Mid-field area mean was below the normal range lower boundary.
- In the Near-field area, 2018 mean values were similar to the corresponding 2015 values for all AEMP benthic variables. For all years, mean values for the AEMP variables were within their respective normal ranges, with the exception of mean density in 2016 that may be attributed to the influence of the STP discharge and the subsequent increase in phosphorus loadings to the Near-field area in 2016.

Key Question: Is the benthic invertebrate community affected by potential Mine-related changes in water and sediment quality in Meliadine Lake?

During the first year of the Mine effluent discharge, the Near-field area was found to have significantly lower density and BCI values compared to the pooled reference areas. There were no significant differences in LTL richness, SDI, SEI or BCI (pairwise method or EEM method relative to Reference 1 median) between benthic communities in exposure and reference areas. These findings were supported by multivariate analysis, which also found the Near-field area to be significantly different from the Mid-field area and the two Reference areas in 2018, although the benthic communities in these areas did show some overlap.

The observed difference in density between the Near-field and the pooled reference area could, at least in part, be due to documented pre-discharge differences in sediment composition between the Near-field area and the reference areas. As part of the 2018 AEMP, normal ranges were developed that considered pre-discharge and reference area variability in Melidaine Lake benthic community structure. Even though 2018 Near-field mean density was lower than in other areas, and was similar to that reported in 2015 under pre-construction conditions, it was within the normal range. All other AEMP variables also had mean values within normal ranges in all sampling areas.

Overall, the 2018 AEMP results indicate that benthic community has not been measurably affected by potential Mine-related changes in water and sediment quality in Meliadine Lake. Benthic invertebrate variables in the Near-field area were within their respective normal ranges. Statistical comparisons between areas did identify some significant differences between Near-field and reference areas, but these appeared to reflect pre-discharge differences in sediment composition among areas.

The 2018 data indicate that the current AEMP Design Plan is able to detect Mine-related differences in benthic invertebrate communities between exposure and reference areas in Meliadine Lake. As more benthic invertebrate data are collected through the AEMP and EEM programs, spatial trends and temporal trends relative to the normal range will be further evaluated.

9.6 Recommendations

No recommendations are provided for changes to benthic invertebrate monitoring under the EEM or AEMP.

10.0 FISH HEALTH

10.1 Introduction

Agnico Eagle's Mine triggered into an EEM in 2017 due to dewatering activities which resulted in a discharge to Meliadine Lake. The fish health component of the EEM evaluates potential differences in indicators of fish health (e.g., energy storage, energy usage, and survival) between the exposure area of Meliadine Lake (i.e., the Near-field area) and one reference area (i.e., Reference Area 1), resulting from the development and operations of the Mine.

The objectives of the fish health component are to:

- determine whether effluent from the Mine has an effect on the growth, reproduction, survival, or condition of fish in Meliadine Lake
- meet the requirements of Part 2, Schedule 5 of the MDMER regulations (Government of Canada 2018)
- provide data to inform adaptive management intended to reduce or eliminate Mine-related effects to fish health in Meliadine Lake

The 2018 fish health survey was implemented to meet EEM sampling requirements and was not intended to meet the specific requirements of the Mine's AEMP fish health component. Specifically, the 2018 fish health survey did not include: a second reference area, a large-bodied sentinel species, or a fish tissue chemistry component (as neither mercury or selenium concentrations in the effluent triggered a fish tissue study under the MDMER [Government of Canada 2018]). Fish health and tissue chemistry sampling for the AEMP is currently scheduled for 2021.

10.2 Methods

A fish health survey was conducted at the Near-field area and Reference Area 1 of Meliadine Lake from 7 to 20 August 2018. The Near-field area is the same as defined for the AEMP, and was selected as the exposure sampling area at the request of the EEM TAP, instead of the H17 discharge location proposed in the Cycle 1 EEM Study Design (Figure 10.2-1; Golder 2017a). Threespine Stickleback (*Gasterosteus aculeatus*) were targeted for the fish health survey based on their relative abundance in Meliadine Lake (Golder 2018c). A second sentinel species was not included in the fish health assessment as no other small-bodied fish species have been captured historically in sufficient abundance to meet EEM sample size requirements, as discussed in the Cycle 1 EEM Study Design (Golder 2017a). Therefore, both a population (i.e., lethal and non-lethal) and a lethal survey were completed with Threespine Stickleback. A brief description of the fish sampling methods are provided in Sections 10.2.1 to 10.2.3. A more detailed description of fish sampling methods is provided in the Cycle 1 EEM Study Design (Golder 2017a).

10.2.1 Field Methods

Fishing methods suitable for nearshore habitats were used to collect Threespine Stickleback from Meliadine Lake, including minnow traps and dip nets. An overview of the sampling area is provided in Figure 10.2-1. Sampling effort details for the Near-field area and Reference Area 1 are provided in Figure 10.2-2 and Figure 10.2-3, respectively. Water quality variables (i.e., water temperature, DO, conductivity, and pH) were measured daily during sampling. Detailed water quality and sediment quality data are provided for Meliadine Lake in Sections 6 and 8, respectively. Benthic invertebrate data are provided in Section 9.

The target sample sizes for the lethal fish health survey were 20 male, 20 female, and 20 juvenile Threespine Stickleback from each of the sampling areas. Non-lethal data were collected from at least 100 additional Threespine Stickleback in each area to supplement the population survey. Non-target species captured during sampling were enumerated, measured, weighed, and assessed for external abnormalities prior to live release near the location of capture. Each fish processed was assigned a unique fish identification number.

The following information was recorded for each sampling effort:

- time (in hours) for each fishing effort and gear type
- gear specific parameters (e.g., trap dimensions)
- water depth of each gear-type set
- latitude and longitude coordinates of each fishing effort
- substrate type (e.g., mud, sand, gravel, cobble) at each fishing location
- water quality field measurements (e.g., DO, water temperature, pH, and conductivity), once daily from the area sampled
- weather (e.g., air and water temperature, precipitation, wind velocity and direction)
- fishing effort identification number (i.e., a unique number for each sampling effort)
- number and species of fish captured
- photographs of representative habitat types and fish species captured

10.2.2 Population Survey

Threespine Stickleback included in the population survey were sampled using a combination of lethal and non-lethal methods. All fish included in the population survey underwent an external examination and total length (±1 mm) and total body weight (±0.001 g) were recorded. Any features that did not appear normal (i.e., deformities, erosions, lesions, tumours, or external parasites) were documented. Fish that were sampled using non-lethal methods were released near the capture location after processing.

10.2.3 Lethal Survey

Fish processed during the lethal survey were each assigned a fish identification number and underwent an external examination as described in the EEM TGD (Environment Canada 2012). Features of the fish that did not appear normal were documented (e.g., occurrence of deformities, erosion, lesions, tumours, or external parasites). Total length (±0.1 mm) and total body weight (±0.001 g) were recorded. Following the external examination, fish were sacrificed by a concussive blow to the head followed by cervical dislocation (i.e., cutting the spinal cord immediately behind the head). The internal organs were immediately assessed and any abnormalities in size, shape or colouration were documented. The liver and gonads were removed and weighed (±0.001 g). Sex and reproductive stage were assigned for each fish based on a visual examination of the gonads at the time of sampling using macroscopic features described in Table 10.2-1. Gonads were transferred to clean sample containers, preserved in 10% buffered formalin, and labelled with the fish identification number. Gonad histology and fecundity samples were submitted for respective analyses as described in Section 10.2.3.1 and Section 10.2.3.2. Carcasses were labeled with the fish identification number, frozen at -20°C and archived at the Golder Edmonton office for possible future chemistry analyses. Otoliths were extracted from frozen carcasses, dried, and submitted for aging analyses (Section 10.2.3.3).

10.2.3.1 Histology

Gonad samples from Threespine Stickleback were submitted to Dr. Dave Groman at the University of Prince Edward Island, Atlantic Veterinary College to confirm sex and maturity of lethally sampled fish. Sex and maturity were determined based on a histological assessment of gonad tissues with the aid of a light microscope, as per histological features listed in Table 10.2-1. Prior to interpretation, samples were prepared for histology by fixation, dehydration, clearing, embedding, sectioning, and staining.

To verify that data quality objectives were met, histology results were cross-referenced with field designated sex and maturity stages, external and internal photographs, as well as biological data (e.g., gonad weight, and fish length). Outliers and fish identified near the size-at-maturity were selected for reassessment by the lab to confirm the accuracy of their sex and/or reproductive staging assignments. The separation of adults and juveniles was determined after consideration of field assessments, gonad weight and histology results. If there were inconsistencies between field assessments and histology results, gonad histology results were weighed more heavily, with consideration of all available data to assign the final gonad maturity categories and sex determination.

10.2.3.2 Fecundity

Threespine Stickleback fecundity samples were processed by qualified biologists at the Golder Saskatoon office. Fecundity (i.e., the number of ripening eggs contained within the ovaries) was estimated by counting the number of ripening eggs present in a subsample of Threespine Stickleback ovarian tissue. Fecundity was then calculated using the following formula:

$$Fecundity = Subsample\ Egg\ Count * \frac{Ovary\ Weight\ (g)}{Subsample\ Weight\ (g)}$$

Mean egg size was determined by measuring the diameter of 30 eggs. To verify that data quality objectives were met, 10% of samples were independently verified by a second qualified biologist.

10.2.3.3 Aging

Otoliths collected from Threespine Stickleback were submitted to North/South Consultants Inc. (Winnipeg, Manitoba) for fish aging analysis. Whole otoliths from individual fish were mounted on slides to estimate age based on the number of annuli observed under a dissection microscope. To verify that data quality objectives were met, 10% of age estimates were independently verified by a second qualified biologist.

Table 10.2-1: Gonad Maturity Stages Used During the Meliadine Lake Fish Health Assessment, August 2018

Sex	Stage	Code	Macroscopic Features	Histological Features
Female	Unknown stage	10	Unable to determine stage.	Unable to determine stage.
	Immature	11	Small ovaries, often clear, blood vessels indistinct.	Only oogonia and PG oocytes present. No atresia or muscle bundles. Thin ovarian wall and little space between oocytes.
	Early Stage Development	12	Enlarging ovaries, blood vessels more distinct. Granular in appearance.	PG, CA, Vtg1, and Vtg2 oocytes present. No evidence of POFs or Vtg3 oocytes. Some atresia can be present.
	Late Stage Development	13	Large ovaries filling the body cavity, prominent blood vessels. Individual oocytes visible.	Vtg3 oocytes present or POFs in batch spawners. Atresia of vitellogenic and/or hydrated oocytes may be present. Early stages of OM can be present.
	Ripe	14	Eggs released with gentle pressure on abdomen.	Oocytes undergoing late OM including GVM, GVBD and hydration, or ovulation.
	Spent	15	Deflated ovaries, blood vessels prominent.	Presence of oocyte atresia and, in some species, POFs. Few if any Vtg2 or Vtg3 oocytes.
	Reabsorbing	16	Small atretic oocytes throughout the ovaries, which are hard and white.	Advanced stage oocytes are atretic and no POFs are present.
	Resting	17	Small ovaries, blood vessels reduced but present.	Only oogonia and PG oocytes present. Muscle bundles, enlarged blood vessels, thick ovarian wall, atresia and degenerating POFs may be present.

Table 10.2-1: Gonad Maturity Stages Used During the Meliadine Lake Fish Health Assessment, August 2018

Sex	Stage	Code	Macroscopic Features	Histological Features
Male	Unknown stage	20	Unable to determine stage.	Unable to determine stage.
	Immature	21	Small testes, often clear and threadlike.	Sg1 only; no lumen in lobules.
	Early Stage Development	22	Small testes, semi-translucent, but easily identified.	Spermatocysts evident along lobules. Sg2, Sc1, Sc2, St and Sz can be present in spermatocysts. Sz not present in lumen of lobules or in sperm ducts. GE continuous throughout.
	Late Stage Development	23	Testes large, firm and lobate. White to purplish in colour. Granular appearance.	Sz in lumen of lobules and/or sperm ducts. All stages of spermatogenesis (Sg2, Sc, St, Sz) can be present. Spermatocysts throughout the testis, active spermatogenesis. GE may be continuous or discontinuous.
	Ripe	24	Milt released with gentle pressure on abdomen.	Based on macroscopic observation only.
	Spent	25	Small and deflated testes. Blood vessels obvious. Violet-pink in colour.	Residual Sz present in lumen of lobules and in sperm ducts. Widely scattered spermatocysts near periphery containing Sc2, St, Sz. Little to no active spermatogenesis. Spermatogonial proliferation and regeneration of GE common in periphery of testes.
	Reabsorbing	26	Not typically observed in males.	Not typically observed in males.
	Resting	27	Small testes, often threadlike.	No spermatocysts. Lumen of lobule often nonexistent. Proliferation of spermatogonia throughout testes. GE continuous throughout. Small amount of residual Sz occasionally present in lumen of lobules and in sperm duct.

Note: Modified from Brown-Peterson et al. (2011).

CA = cortical alveolar; GVBD = germinal vesicle breakdown, GVM = germinal vesicle migration, OM = oocyte maturation, PG = primary growth, POF = postovulatory follicle complex, Vtg1 = primary vitellogenic, Vtg2 = secondary vitellogenic, Vtg3 = tertiary vitellogenic, GE = germinal epithelium, Sc1 = primary spermatocyte, Sc2 = secondary spermatocyte, Sg1 = primary spermatogonia, Sg2 = secondary spermatogonia, St = spermatid, Sz = spermatozoa.

10.2.4 Data Analysis

Data screening was performed prior to statistical analyses. Fish health data were screened for potential data entry errors or unusual data using box plots and scatterplots to visually examine data. Plots included total length versus carcass weight, carcass weight versus gonad weight, standard length versus total length, total length versus total body weight, carcass weight versus liver weight, total body weight versus carcass weight, age versus total length, age versus total body weight, age versus carcass weight, and age versus gonad weight. Outliers, as detected by the qualitative screening, were removed from the dataset only if they were determined to be the result of human error (i.e., sampling or measurement error). All outliers were checked with field data sheets and field photos as part of the screening process prior to removal from the dataset.

Data collected during the fish health program were compared among sampling areas to identify and quantify potential differences in effect endpoints between the Near-field and Reference Area 1. Endpoints were considered as either “effect” or “supporting” endpoints. Effect endpoints included specific parameters measured to determine whether there were any effects on indicators of survival, energy use, and energy storage among fish populations (Environment Canada 2012). Supporting endpoints included parameters measured to support the interpretation of potential differences in effect endpoints. A list of measured effect and supporting endpoints for the population

survey and the lethal survey are provided in Table 10.2-2 and Table 10.2-3, respectively. The magnitude of differences in effect endpoints were compared to CES as defined in the MDMER (Government of Canada 2018), which establish effects thresholds indicative of a potential risk to the environment (e.g., greater than 10% for relative body weight and greater than 25% for relative liver size and relative gonad size). In cases where sexes were compared separately (i.e., the lethal survey), only fish with sexes confirmed through histology were included in the statistical analysis.

Table 10.2-2: Statistical Procedures Used in the Population Survey

Indicator	Parameter	Endpoint	CES	Response Variable (Y)	Covariate (X)	Statistical Procedure
Survival	Length-frequency	Effect[a]	-	-	-	K-S test
Growth (energy use)	Length (immature fish)	Effect	25%[b]	Total length	-	ANOVA
	Body weight (immature fish)	Effect	25%[b]	Body weight	-	ANOVA
Reproduction (energy use)	YOY relative abundance	Effect	-	YOY relative abundance	-	Fisher's Exact Test
Condition (energy storage)	Relative body weight	Effect	10%	Body weight	Length	ANCOVA

a) Length-frequency is an effect endpoint for non-lethal sampling in the EEM program; however, because effect sizes are not expressed as a magnitude, but rather a maximum percent difference, there are no defined CES.

b) Critical effect size is applied herein but is not defined for the specific endpoint in the MDMER.

CES = critical effect size ; % = percent; K-S = Kolmogrov-Smirnov test; ANOVA = analysis of variance; ANCOVA = analysis of covariance; YOY = young-of-the-year; - = not applicable.

Table 10.2-3: Statistical Procedures Used in the Lethal Survey

Indicator	Parameter	Endpoint	CES	Response Variable (Y)	Covariate (X)	Statistical Procedure
Survival	Length	Effect[a]	25%	Total length	-	ANOVA
Growth (energy use)	Weight-at-age	Effect	25%	Body weight	Age	ANCOVA
Reproduction (energy use)	Relative gonad size	Effect	25%	Gonad weight	Body weight	ANCOVA
Condition (energy storage)	Relative body weight	Effect	10%	Body weight	Total length	ANCOVA
	Relative liver weight	Effect	25%	Liver weight	Body weight	ANCOVA
		Supporting	-	Liver weight	Total length	ANCOVA
	Relative egg size	Supporting	-	Egg size	Body weight	ANCOVA

a) Threespine Stickleback are short-lived in freshwater, so length was used as a surrogate for age (Environment Canada 2012).

CES = critical effect size ; % = percent; # = number; K-W = Kruskal-Wallis test; ANOVA = analysis of variance; ANCOVA = analysis of covariance; - = not applicable.

10.2.5 Descriptive Statistics

Catch-per-unit effort (CPUE) was calculated to provide an estimate of abundance by standardizing catch data to fishing effort. The CPUE was calculated separately for each species and was summarized by sampling area and gear type. For minnow traps, CPUE was calculated as the number of fish captured per trap per hour. For dip nets, CPUE was calculated as the number of fish captured per 100 seconds of sampling effort.

Descriptive statistics were calculated for individual fish health parameters, separated by sex, life stage (i.e., adult or juvenile), and sampling area. Descriptive statistics included sample size, median, arithmetic mean, standard deviation (SD), standard error (SE), and minimum and maximum values. Fish health indices were calculated as follows:

$$Condition\ Factor\ = \left(\frac{body\ weight}{length^3}\right) \times\ 100{,}000$$

$$Gonadosomatic\ index\ = \left(\frac{gonad\ weight}{body\ weight}\right) \times 100$$

$$Liver\ somatic\ index = \left(\frac{liver\ weight}{body\ weight}\right) \times 100$$

Weight and length measurements were reported in units of grams (g) and millimetres (mm), respectively.

Visual comparisons for fish health data were made using censored box plots as outlined in Barrett et al. (2014). The censored boxplots were defined using the minimum values, the quartiles, and the maximum values. Values that were 1.5 times the interquartile range beyond the quartiles were considered extreme and plotted individually. When extreme values were present, the whiskers were truncated to the next value in the dataset that was within 1.5 times the interquartile range beyond the quartiles (i.e., the whiskers may not always extend to the full 1.5 times the interquartile range if the next value in the dataset is closer to the quartile than the full 1.5 times the interquartile range).

10.2.6 Inferential Statistics

Statistical comparisons were conducted among sampling areas for fish health endpoints presented in Table 10.2-2 and Table 10.2-3. Differences in the length and body weight were compared among sampling areas using ANOVA. Differences in weight-at-age, relative gonad size, relative body weight, relative liver size, and relative egg weight were compared among sampling areas using analysis of covariance (ANCOVA). Significant differences between sampling areas were determined using an α of 0.1. As tapeworms were frequently observed in Threespine Stickleback captured from the Near-field area and Reference Area 1, inferential statistics were completed both with and without parasitized fish included (Golder 2017a).

The assumptions of ANOVA and ANCOVA are that the residuals of the data, after being fit to the model, are normally distributed and have equal variance between groups. The assumption of normality was assessed using the Shapiro-Wilk test, while Levene's test was used to assess equality of variances. Significant differences in assumptions were evaluated using an α of 0.05. If the assumptions of normality and equality of variance were not met, the data were $\log_{10}$-transformed and the assumptions were re-tested. When the assumptions could not be met using a $\log_{10}$ transformation, the non-parametric K-W test was used instead of ANOVA, while ANCOVA data were rank transformed. In addition to the assumptions of normality and equality of variance, ANCOVA has the additional assumption that the parameter regression slopes are parallel among sampling areas. To test this

assumption, the ANCOVA was conducted by first fitting separate regression models for each sampling area using a general linear model that included an interaction term between the sampling area and covariate:

Full ANCOVA model: $y = \beta_0 + \beta_1(x) + \beta_2(Area) + \beta_3(x) \times (Area) + \varepsilon$

where y is the response variable, x is the covariate, $Area$ is the sampling area indicator variable, and ε is the error term. If the coefficient β_3 of the $(x) \times (Area)$ interaction term was not significant (i.e., p>0.05), then the slopes were considered parallel and the ANCOVA proceeded by testing the significance of the coefficient β_2 of the $(Area)$ term in the reduced ANCOVA model that fits separate regressions for each area, but with a common regression slope:

Reduced ANCOVA model: $y = \beta_0 + \beta_1(x) + \beta_2(Area) + \varepsilon.$

When a significant interaction was observed, the regression slopes were considered significantly different. When the covariate was a strong predictor of the response variable and the ANCOVA had a high coefficient of determination (R^2 >0.8), the test for parallel slopes had high power to detect a difference that may not be practically significant. In this case, when the interaction term in the full ANCOVA model was significant, the slopes were fixed as parallel by fitting the reduced ANCOVA model because the reduced model explained almost as much (within 2%) of the variability in the response variable as the full model. In this case, the ANCOVA proceeded under the assumption that the regression slopes between groups were practically similar (Barrett et al. 2010).

Statistical outliers were evaluated using SRs from the ANOVA and ANCOVA models. Statistical outliers were identified with a SR value of plus or minus (±) 4.0 (Golder 2017a). When an outlier was detected, the validity of the data point was examined. If the outlier was determined to be the result of a data entry error, it was corrected; if the outlier was not the result of data entry error and could not be resolved otherwise, the analysis was completed with and without outliers included.

When significant differences in fish health parameters were observed between sampling areas, the magnitude of difference between the Near-field area and Reference Area 1 was calculated by expressing the difference as a percentage of the mean as follows:

Magnitude: $Magnitude = \frac{\bar{x}_{NF} - \bar{x}_{RA1}}{\bar{x}_{RA1}} * 100$

where $\bar{x}_{NF}$ is the mean or median value for the effect endpoint at the Near-field area, and $\bar{x}_{RA1}$ is the mean or median value for the effect endpoint at Reference Area 1. A positive magnitude of difference indicated that values were greater in the Near-field area than Reference Area 1, while a negative magnitude of difference indicated that values were greater in Reference Area 1 than the Near-field area.

If the statistical comparison was conducted on $\log_{10}$-transformed data, then the magnitude was calculated using geometric means. If the statistical comparison between sampling areas was conducted using the K-W test, the data were not considered to be normally distributed and the magnitude was calculated using medians. As the K-W test is a non-parametric method for testing whether samples originate from the same distribution (i.e., it is not a comparison of sample medians), there was the potential for the K-W test to be significant, but no differences in medians observed. For effect endpoints analyzed using ANCOVA, magnitudes were calculated from the least squares means.

Length-frequency distributions were compared among sampling areas using the non-parametric, two-sample Kolmogorov-Smirnov (K-S) test. The K-S test compares the cumulative relative distributions of total length between sampling areas by comparing the maximum difference between the two cumulative relative frequency distributions to a critical value, which is determined based on sample size, to assess whether the difference is large enough to indicate that the two distributions came from different populations. Differences in the length of Threespine Stickleback were compared among gear types using the K-W test. The prevalence of abnormalities were compared among sampling areas using the chi-square test.

10.2.7 Power Analysis

Power analyses were performed to determine the statistical power and sample size requirements to detect a magnitude of change that was equivalent to CESs defined in the MDMER as presented in Table 10.2-2 and Table 10.2-3 (Government of Canada 2018). Type I (α) and Type II (β) error rates were set to 0.1 (Environment Canada 2012); therefore, sufficient power was considered to be 0.9 (i.e., 1- β). Power analyses were conducted using the power and sample size function in G*Power 3.1 (Faul et al. 2007). Power analyses were only completed for endpoints with defined CES (Government of Canada 2018).

10.3 Quality Assurance and Quality Control

QA and QC procedures were applied to field sampling, laboratory analyses, data entry, data analyses, and report preparation. Pre-field meetings were held with the field crew prior to the start of the program to review specific work instructions for the field data collection, and to confirm that the field crew were familiar with the expectations of the sampling plan. Field equipment were calibrated throughout the field program following manufacturer specifications and all samples were collected by experienced personnel. Samples were labelled, preserved, and shipped according to standard protocols. Detailed field notes were recorded in waterproof field books and on pre-printed waterproof field data sheets in either pencil or indelible ink. Data sheets and sample labels were checked at the end of each field day for completeness and accuracy and were scanned into electronic copies at the completion of the field program. Chain-of-custody forms were used to track shipment and receipt of samples.

10.4 Results and Discussion

10.4.1 Catch Data Summaries

A total of 1,226 fish from four species were captured during the August 2018 small-bodied fish health survey at Meliadine Lake (Table 10.4-1). Fish were captured using a combination of minnow traps and dip netting. The spatial extent of sampling was indicated for the Near-field area in Figure 10.2-2, and Reference Area 1 in Figure 10.2-3. Species richness varied among sampling areas, with two species captured from the Near-field area and four species from Reference Area 1. Catch varied among sampling areas, with 905 fish captured at the Near-field area and 321 fish captured at Reference Area 1. Catches at each sampling area were dominated by Threespine Stickleback, accounting for 99% of the total catch at the Near-field area and 94% of the catch at Reference Area 1. Threespine Stickleback CPUE varied among sampling areas, with the majority of Threespine Stickleback captured using minnow traps in Meliadine Lake (Table 10.4-2). The CPUE of Threespine Stickleback captured using minnow traps was 0.44 fish per hour at the Near-field area and 0.11 fish per hour at Reference Area 1.

Table 10.4-1: Species Richness and Abundance of Fish Captured at Meliadine Lake, 2018

Species	Near-field Area	Reference Area 1	Total
Threespine Stickleback (*Gasterosteus aculeatus*)	899	301	1,200
Ninespine Stickleback (*Pungitius pungitius*)	6	18	24
Slimy Sculpin (*Cottus cognatus*)	0	1	1
Burbot (*Lota lota*)	0	1	1
Species Richness	2	4	4
Abundance	905	321	1,226

Table 10.4-2: Catch-Per-Unit Effort for Fish Captured from Meliadine Lake, 2018

Area	Sampling Method	Sampling Effort		THST	NNST	SLSC	BURB	Total
NF	Minnow Trap	2049 h	Abundance	899	6	0	0	905
			CPUE #/h	0.44	<0.01	0.00	0.00	0.44
RA1	Minnow Trap	2692 h	Abundance	298	18	1	1	318
			CPUE #/h	0.11	<0.01	<0.01	<0.01	0.12
	Dip Net	3600 s	Abundance	3	0	0	0	3
			CPUE #/100 s	0.08	0.00	0.00	0.00	0.08

NF = Near-field Area; RA1 = Reference Area 1; THST = Threespine Stickleback; NNST = Ninespine Stickleback; SLSC = Slimy Sculpin; BURB = Burbot; CPUE = catch-per-unit-effort; # = number of fish; h = hour; s = second; <= less than.

Water quality measurements were comparable among the Near-field area and Reference Area 1 in 2018. Water temperatures ranged from 10.2 to 12.7°C at the Near-field area and 9.0 to 12.6°C at Reference Area 1. At the Near-field area, pH ranged from 5.9 to 7.4 versus 6.1 to 7.3 at Reference Area 1. DO concentrations ranged from 9.8 to 11.3 mg/L at the Near-field area and 9.2 to 12 mg/L at Reference Area 1. Specific conductivity ranged from 86 to 106 µS/cm at the Near-field area and 71 to 79 µS/cm at Reference Area 1. Fish sampling effort and supporting environmental data are provided for each sampling area in Appendix 10A. Detailed water quality and sediment quality data are provided for Meliadine Lake in Sections 6 and 8, respectively.

10.4.2 Population Survey

A total of 1,200 Threespine Stickleback were captured during the Meliadine Lake fish health program (Table 10.4-1). Of these, 216 were sampled during the lethal survey and an additional 654 Threespine Stickleback were processed using non-lethal methods (Appendix 10B). A combined total of 870 Threespine Stickleback were included in the population survey; 570 fish were collected in the Near-field Area and 300 fish were collected in Reference Area 1. An additional 330 individuals were released without processing to minimize hold times and reduce the risk of incidental mortalities.

Threespine Stickleback sample size targets for the population survey were met at each of the sampling areas. Descriptive statistics for the Threespine Stickleback population survey are provided in Table 10.4-3, with the results of statistical comparisons presented in Table 10.4-4. Data are provided in Appendix 10B, spatial comparisons are presented in Appendix 10C, and temporal comparisons for the Near-field area between 2018 and 2015 are provided in Appendix 10D.

Table 10.4-3: Descriptive Statistics for Threespine Stickleback Collected from Meliadine Lake, 2018

Stage	Parameter	Near-field Area							Reference Area 1

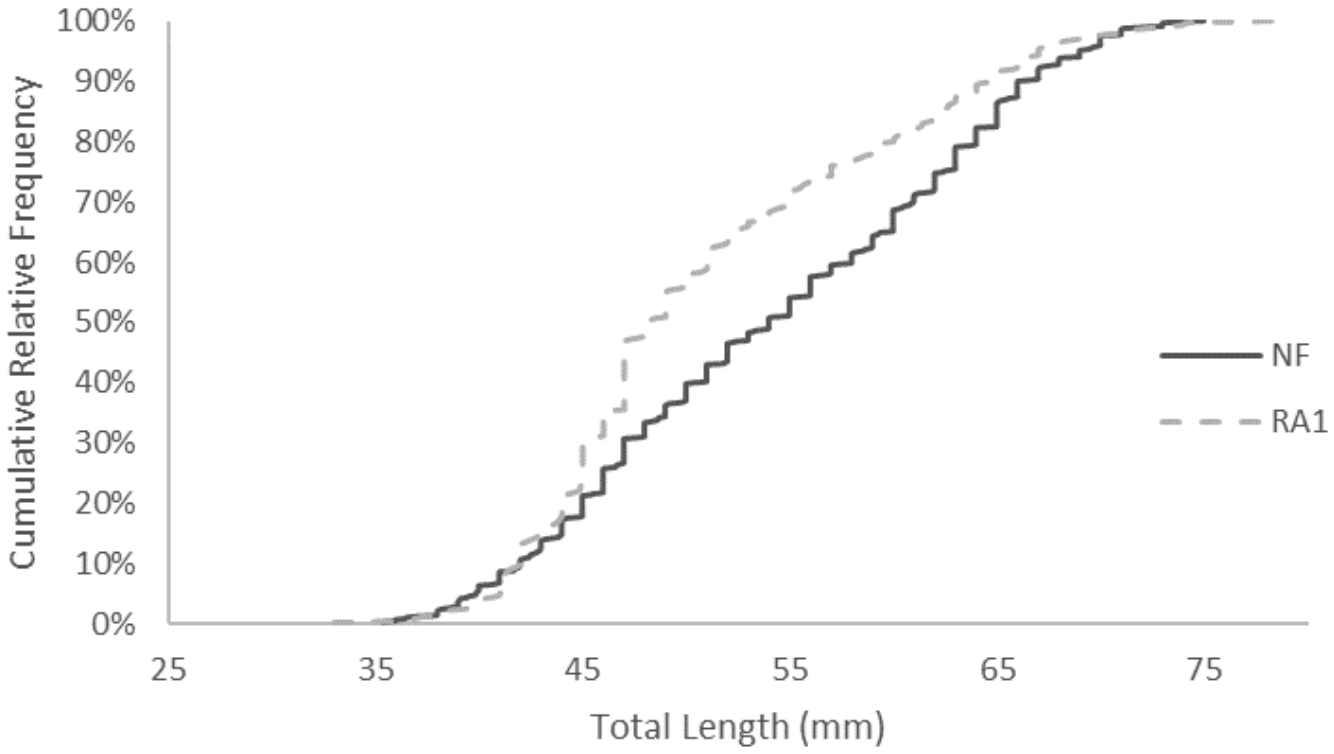
a) Analysis conducted using juvenile fish, defined as individuals below than the size-at-maturity of 44.5 mm.

b) Not tested. No young-of-the-year were captured from either area.

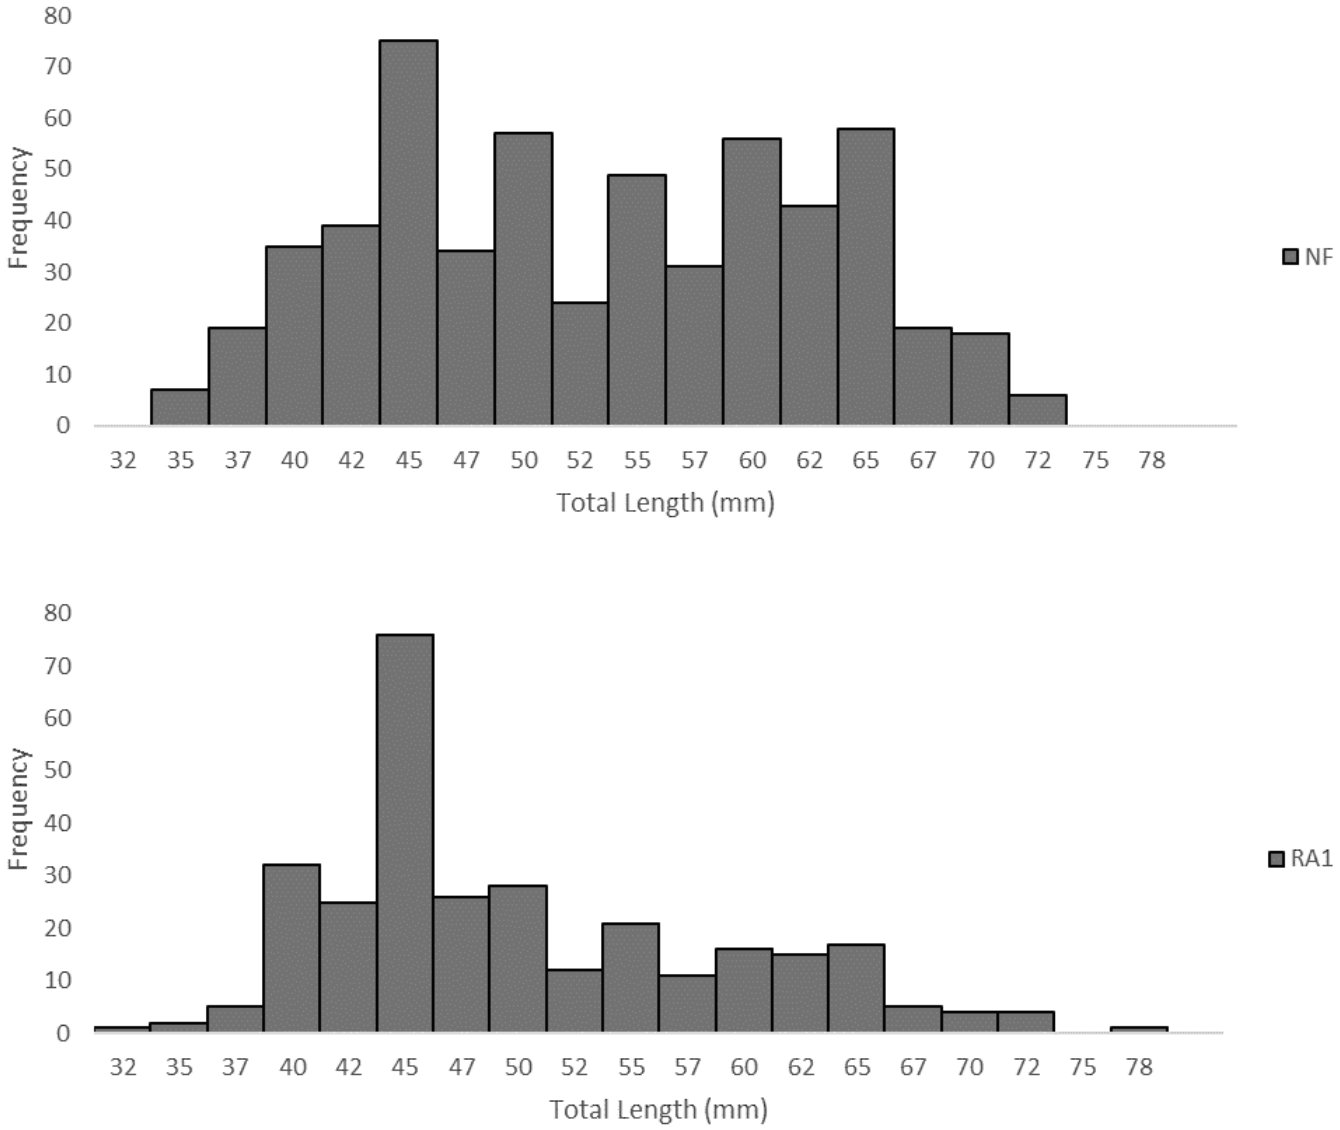
c) Slopes are considered practically similar (Barrett et al. 2010).



d) Magnitude based on maximum percent difference between groups in cumulative frequency distribution.

n = sample size; ; NF = Near-field Area; RA1 = Reference Area 1; *P*-value = probability value; MSE = mean squared error; SSD = statistically significant difference (α= 0.1) ; % = percent; CES = critical effect size; K-W = Kruskal-Wallis; ANCOVA = analysis of covariance; K-S = Kolmogorov-Smirnov; rank = rank transformed data; <= less than; n/a or - = not applicable.

10.4.2.1 Survival

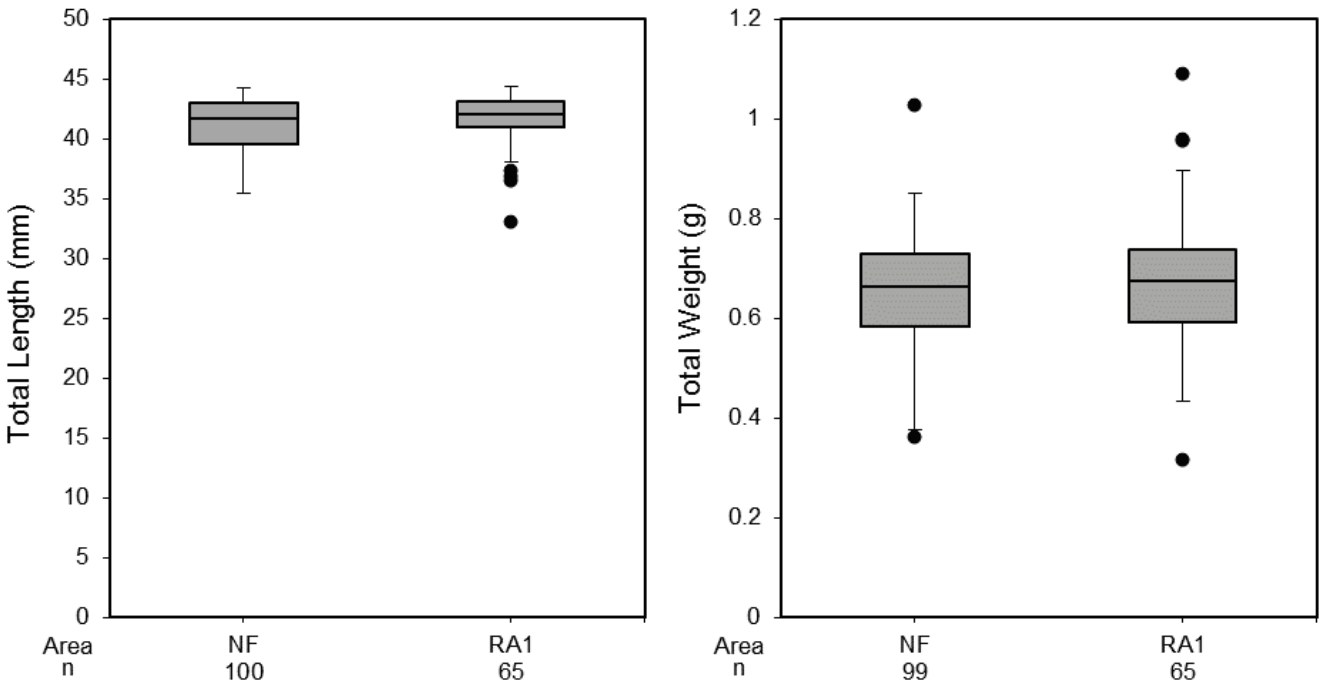


10.4.2.1.1 Length-Frequency

Length-frequency distributions of Threespine Stickleback were significantly different among sampling areas, with a maximum percent difference in cumulative relative frequency of 20% (Table 10.4-4 and Figure 10.4-1). Differences between areas resulted from a greater proportion of larger individuals (i.e., >55 mm) captured from the Near-field area when compared to Reference Area 1 (Figure 10.4-2).

NF = Near-field area; RA1 = Reference Area 1 ; % = percent; mm = millimetre.

Figure 10.4-1: Cumulative Length-Frequency Distribution of Threespine Stickleback Collected from Meliadine Lake, 2018



NF= Near-field Area; RA1 = Reference Area 1; mm = millimetre.

Figure 10.4-2: Length-Frequency Distributions for Threespine Stickleback Collected from Meliadine Lake, 2018

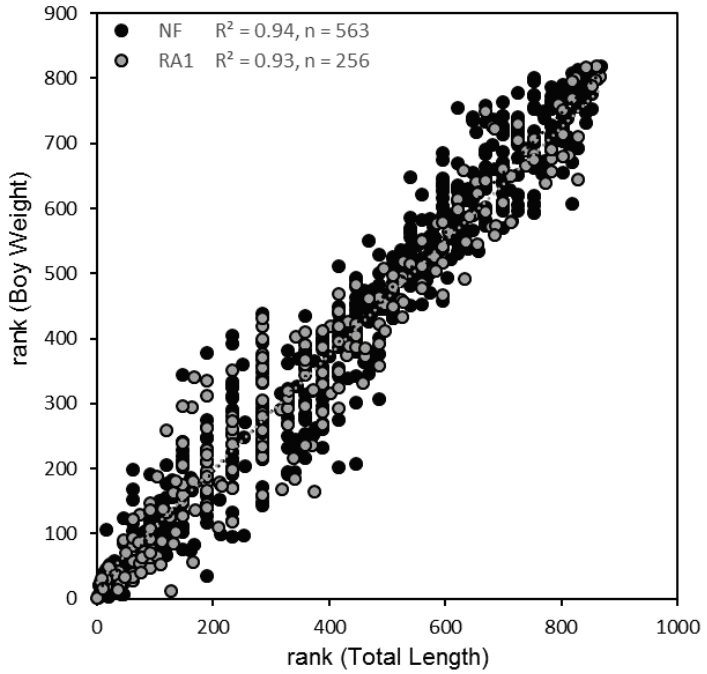
10.4.2.2 Growth

10.4.2.2.1 Size-at-Age

Threespine Stickleback ranged in size from 33.0 to 79.0 mm, and 0.316 to 4.909 g (Table 10.4-3, Figure 10.4-3). There were no significant differences observed for total length and body weight of immature Threespine Stickleback (i.e., individuals smaller than the calculated size-at-maturity of 44.5 mm, Section 10.4.3.2.2) captured from the sampling areas (Table 10.4-4). Statistical power was sufficient to detect a CES of 25% for both total length and body weight. Spatial comparisons of total length and body weight for all fish sampled (i.e., juveniles and adults) are provided in Figures 10C-1 and 10C-2, respectively.

NF = Near-field Area; RA1 = Reference Area 1; n = sample size; mm = millimetre; g = gram.

Figure 10.4-3: Length and Weight of Immature Threespine Stickleback Captured from Meliadine Lake During the Population Survey, 2018



10.4.2.3 Reproduction

No young-of-the-year (YOY) were captured in the Near-field area or Reference Area 1 during the fish heath survey. Therefore, the relative abundance of YOY was not compared between areas. The low catchability of YOY may have been a consequence of the timing and location of sampling effort. Threespine Stickleback were determined to be spawning in Meliadine Lake during the August 2015 and August 2017 sampling periods (Golder 2016c and 2018), based on the presence of male secondary sex characteristics and the occurrence of ripe and spent individuals of both sexes. Similar observations were made in August 2018. Threespine Stickleback are typically a spring spawning species; however, extended spawning seasons have been observed for some populations (Wooton et al. 1978; Chellappa et al. 1989). Based on this information and our observations, Threespine Stickleback likely spawn from June through to August in Meliadine Lake. As a consequence, YOY may have been too small at the time of sampling to be effectively captured, or occupied habitats that were not effectively targeted by the sampling methods employed (e.g., residing within interstitial spaces of the rocky substrate, or at depths greater than 3 m). These results were consistent with previous fish health surveys conducted in Meliadine Lake (i.e., August 2015 and August 2017), that employed a variety of alternative gear types, including beach seines, hoop nets, and backpack electrofishing (Golder 2016c and 2018).

10.4.2.4 Condition

10.4.2.4.1 Condition Factor

Condition factor of Threespine Stickleback collected from Meliadine Lake ranged from 0.54 to 1.29 (Table 10.4-3). Relative body weights were not significantly different among sampling areas (Table 10.4-4), and statistical power was sufficient to detect a CES of 10% for relative body weight.

Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-4). Statistical outliers were excluded.
NF = Near-field Area; RA1 = Reference Area 1; g = gram; mm = millimetre; R^2 = coefficient of determination; n = sample size; rank = rank transformed data.

Figure 10.4-4: Body Weight Relative to Total Length for Threespine Stickleback Collected During the Population Survey from Meliadine Lake, 2018

10.4.3 Lethal Survey

A total of 216 Threespine Stickleback were lethally sampled from Meliadine Lake during the fish health assessment. Target sample sizes were achieved at each sampling area (Table 10.4-5). Descriptive statistics for lethally sampled Threespine Stickleback are provided in Table 10.4-6, with the results of statistical comparisons among sampling areas presented in Table 10.4-7, and statistical comparisons excluding fish parasitized by tapeworms in Table 10.4-8. As sample sizes for unparasitized fish were small (i.e., sample sizes ranged from 13 to 19), results of the lethal survey focused on all Threespine Stickleback sampled. Fish health data and statistical outliers removed from the analyses are provided in Appendix 10B, spatial comparisons for fish health parameters between the Near-field area and Reference Area 1 are presented in Appendix 10C, and temporal comparisons for the Near-field area between 2018 and 2015 are provided in Appendix 10D.

Table 10.4-5: Sample Sizes for Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018

Life Stage	Sex	Target Sample Size	Achieved Sample Size		
			Near-field	Reference Area 1	Total
Adult	Female	20	31	25	56
	Male	20	21	23	43

n = sample size; *P*-value = probability value; MSE = mean squared error; NF = Near-field Area; RA1 = Reference Area 1; CES = critical effect size ; % = percent; K-W = Kruskal-Wallis; ANOVA = analysis of variance; ANCOVA = analysis of covariance; log = log_{10} transformed data; rank = rank transformed data; <= less than; n/a = not applicable.

10.4.3.1 Survival

10.4.3.1.1 Age

Age of Threespine Stickleback sampled from Meliadine Lake[10] during the lethal survey ranged from 1 to 5 years (Table 10.4-6), with the majority of fish sampled reaching sexual maturity between the ages of 1 and 2 (see Figure 10.4-7). As Threespine Stickleback are short-lived, and it can be difficult to detect a 25% difference in age, fish length was used as a surrogate effect endpoint for age (Environment Canada 2012). Lethally sampled female and male Threespine Stickleback ranged in length from 43.1 to 74.1 mm and 44.9 to 65.8 mm, respectively (Table 10.4-6, Figure 10.4-5). No significant differences in length were observed between the Near-field area and Reference Area 1 for female or male Threespine Stickleback. Statistical power was sufficient to detect a CES of 25% for both sexes (Government of Canada 2018).

+

NF = Near-field Area; RA1 = Reference Area 1; n = sample size; mm = millimetre.

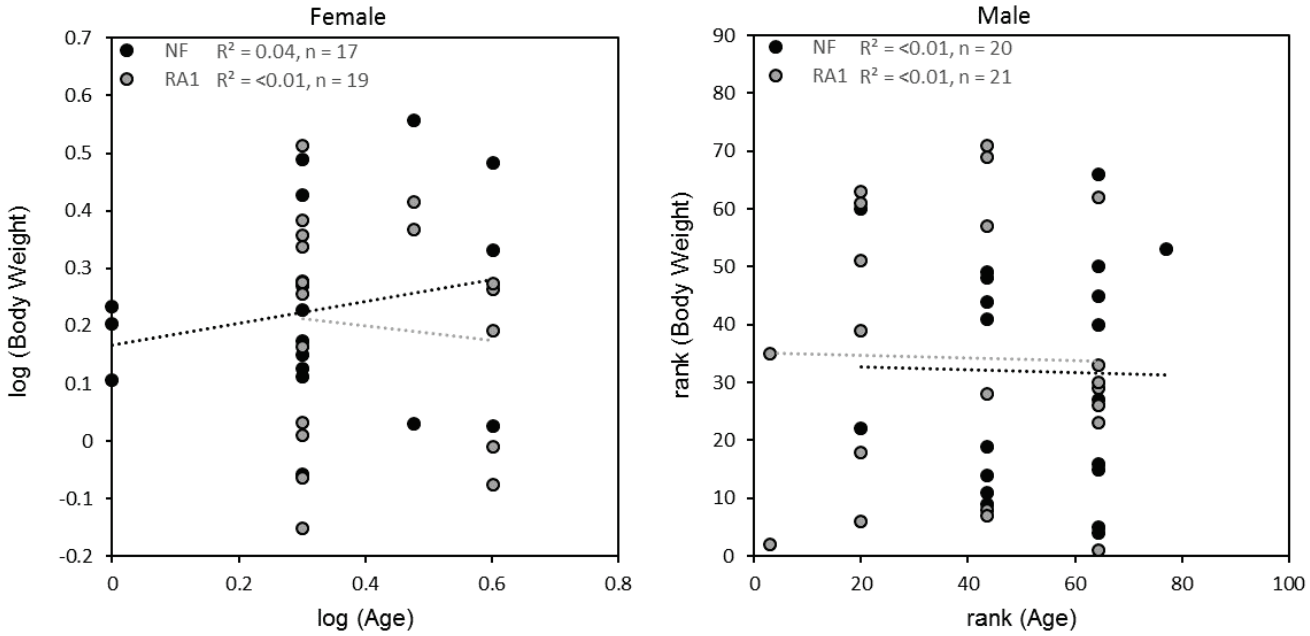

Figure 10.4-5: Length of Female and Male Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018

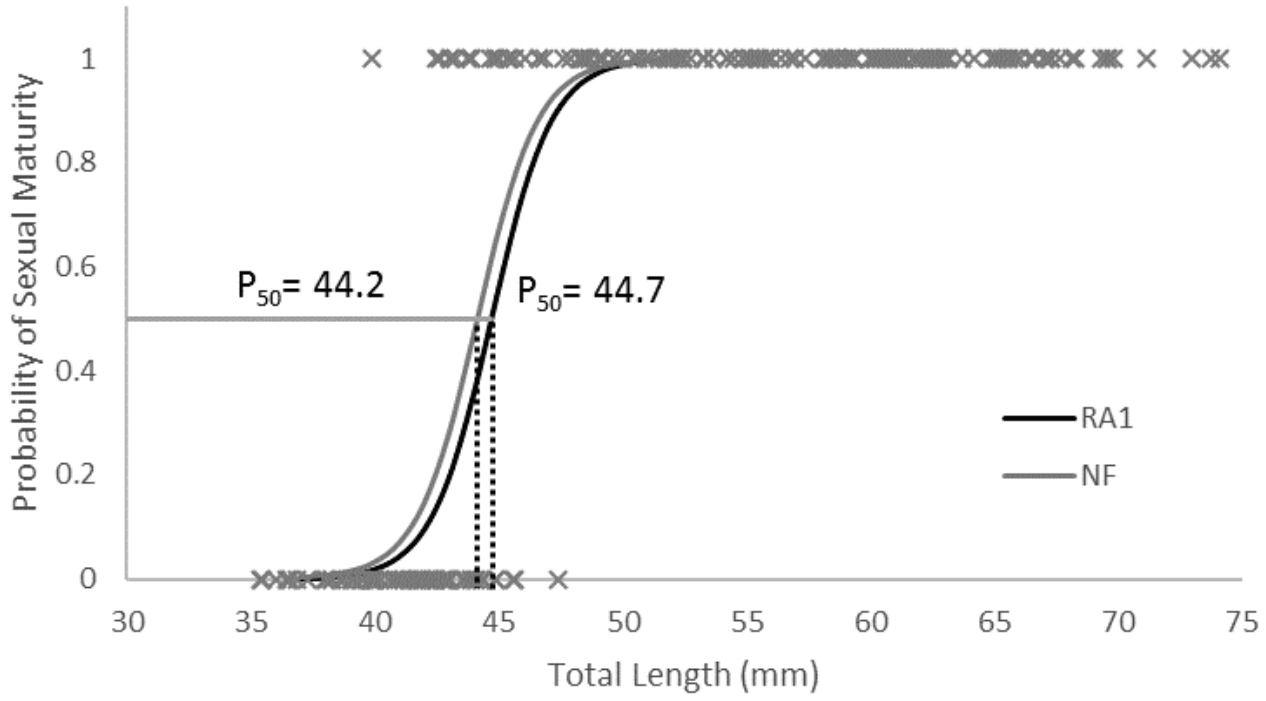
[10] Ages were not assigned based on length-frequency distributions in 2018 as individual modes could not be reconciled with laboratory data. Laboratory assigned ages of Threespine Stickleback ranged from 1 to 5 years; however, only two modes could be distinguished from the length frequency-distribution ranging from 35 mm to 52 mm, and 52 mm to 72 mm (Figure 10.4-5).

10.4.3.2 Growth

10.4.3.2.1 Weight-at-Age

Lethally sampled female and male Threespine Stickleback ranged in total body weight from 0.433 to 4.222 g and 0.706 to 2.596 g, respectively (Table 10.4-3). Using total body weight and laboratory assigned ages, no significant differences in weight-at-age for females or males were observed between the Near-field area and Reference Area 1 (Table 10.4-6, Figure 10.4-6). Laboratory assigned ages were not a strong predictor of body weight (females $R^2 = 0.242$; males $R^2 = 0.198$), resulting in a high degree of variation in the data and a subsequent reduction in statistical power. While statistical power was low for weight-at-age comparisons (i.e., ranging from 0.397 to 0.554 for females and 0.511 for males [Table 10.4-7]), the magnitudes of difference were below the CES of 25%.



Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-7).
NF = Near-field Area; RA1 = Reference Area 1; g = gram; y = year; R^2 = coefficient of determination; n = sample size; log = $\log_{10}$ transformed data; rank = rank transformed data.

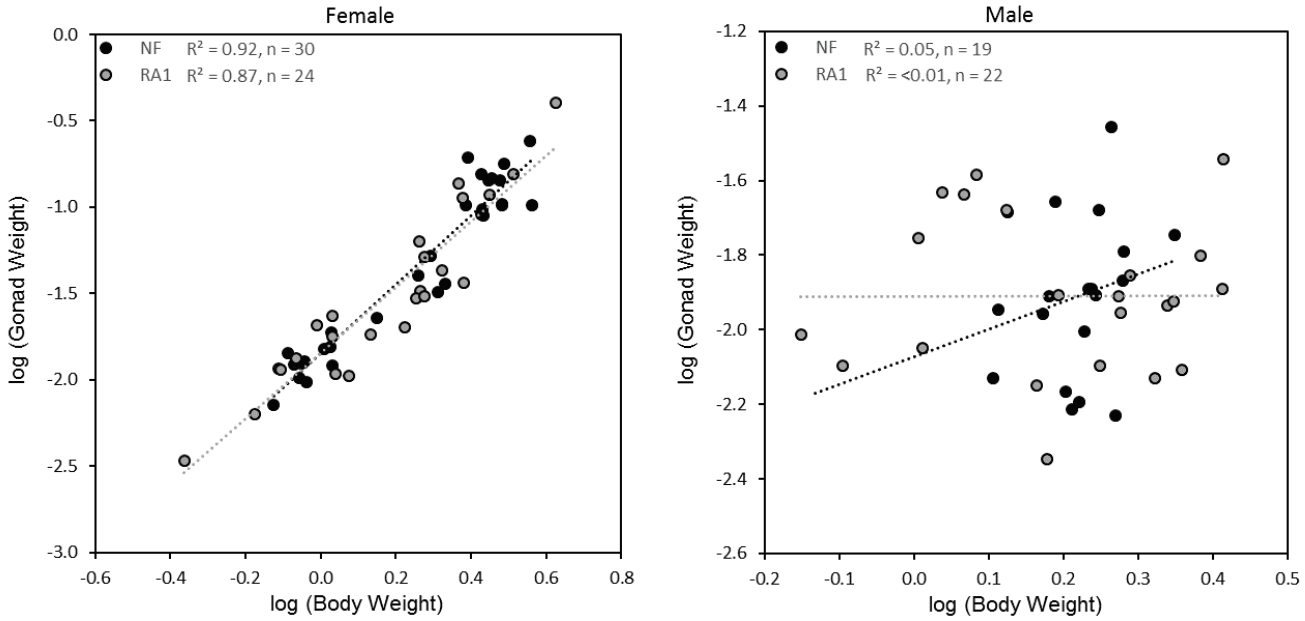
Figure 10.4-6: Body Weight Relative to Age for Female and Male Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018

10.4.3.2.2 Size-at-Maturity

Fish length was a significant predictor of maturity in Threespine Stickleback, based on a binary logistic regression (P<0.001). Size-at-maturity (i.e., the total length at which 50% of the population reaches sexual maturity, or P_{50}) was similar between Near-field area and Reference Area 1 (P = 0.446), with fish maturing at 44.2 and 44.7 mm, respectively (Figure 10.4-7). Size-at-maturity was also similar among fish parasitized and unparasitized by tapeworms (P = 0.784), maturing at 44.4 and 44.7 mm, respectively.

Note: Plotted curve represents the modelled size at maturity. Actual data used in the analysis are represented by the symbol x.
NF = Near-field Area; RA1 = Reference Area 1; P_{50} = the total length at which 50% of the population reach sexual maturity; mm = millimetre.

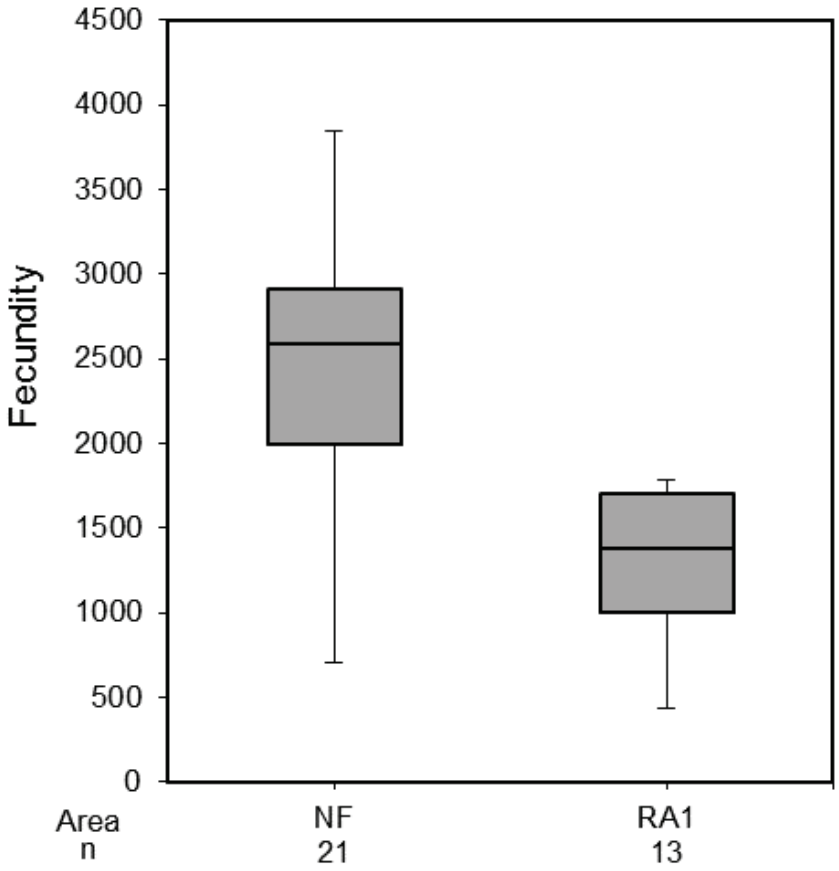
Figure 10.4-7: Size-at-Maturity of Threespine Stickleback at Near-field Area and Reference Area 1, 2018



10.4.3.3 Reproduction

10.4.3.3.1 Relative Gonad Size and Fecundity

The gonadosomatic index for female and male Threespine Stickleback ranged from 0.78 to 19.20 and 0.30 to 2.15, respectively. No significant differences were observed in relative gonad weight for female or male Threespine Stickleback, among sampling areas (Table 10.4-7, Figure 10.4-8). Although statistical power for relative gonad weight was low (i.e., ranging from 0.715 to 0.886 for females and 0.412 to 0.574 for males), the magnitudes of difference observed were below the CES of 25%.

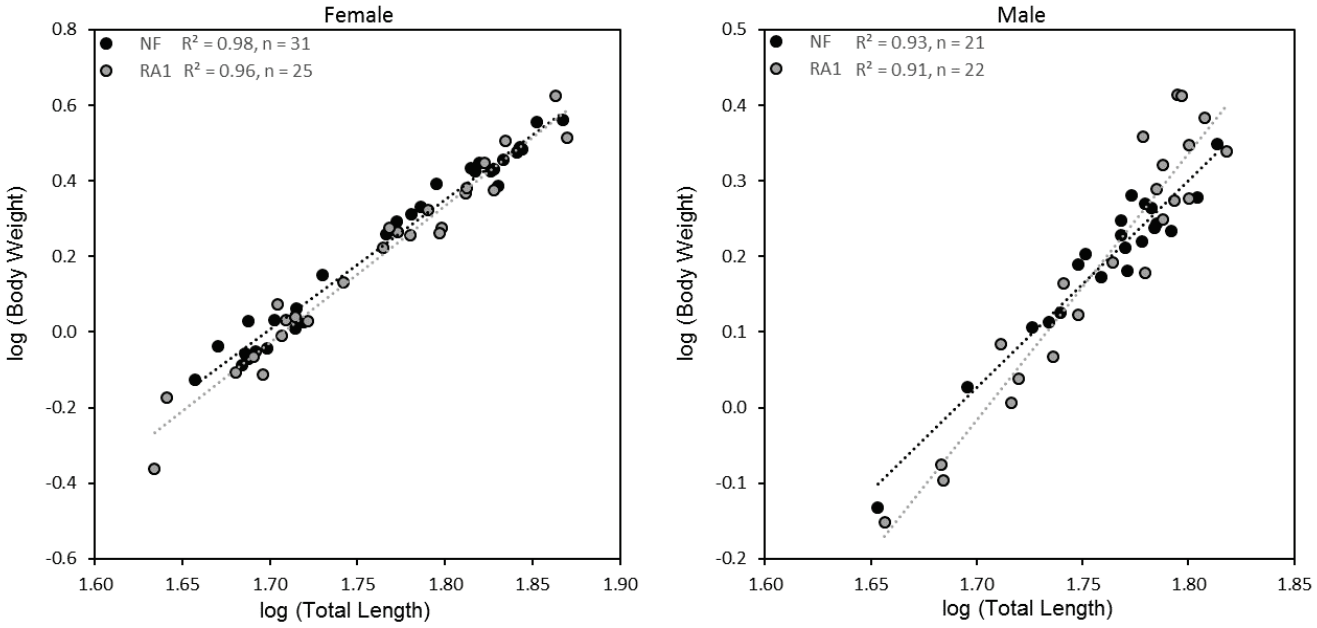


Threespine Stickleback are multiple spawners (Environment Canada 2012), and fish collected in August 2018 included a range of reproductive stages, including early stage development, late stage development, ripe, spent and resting (Table 10.2-1; Appendix 10B). The variability in reproductive stages likely contributed to increased variation in relative gonad size, contributing to the low statistical power observed.

Fecundity of female Threespine Stickleback sampled from Meliadine Lake ranged from 431 to 3845 eggs per female (Table 10.4-6, Figure 10.4-9).

Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-7). Statistical outliers were excluded.
NF = Near-field Area; RA1 = Reference Area 1; g = gram; R^2 = coefficient of determination; n = sample size; log = log10 transformed data.

Figure 10.4-8: Gonad Weight Relative to Body Weight for Female and Male Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018



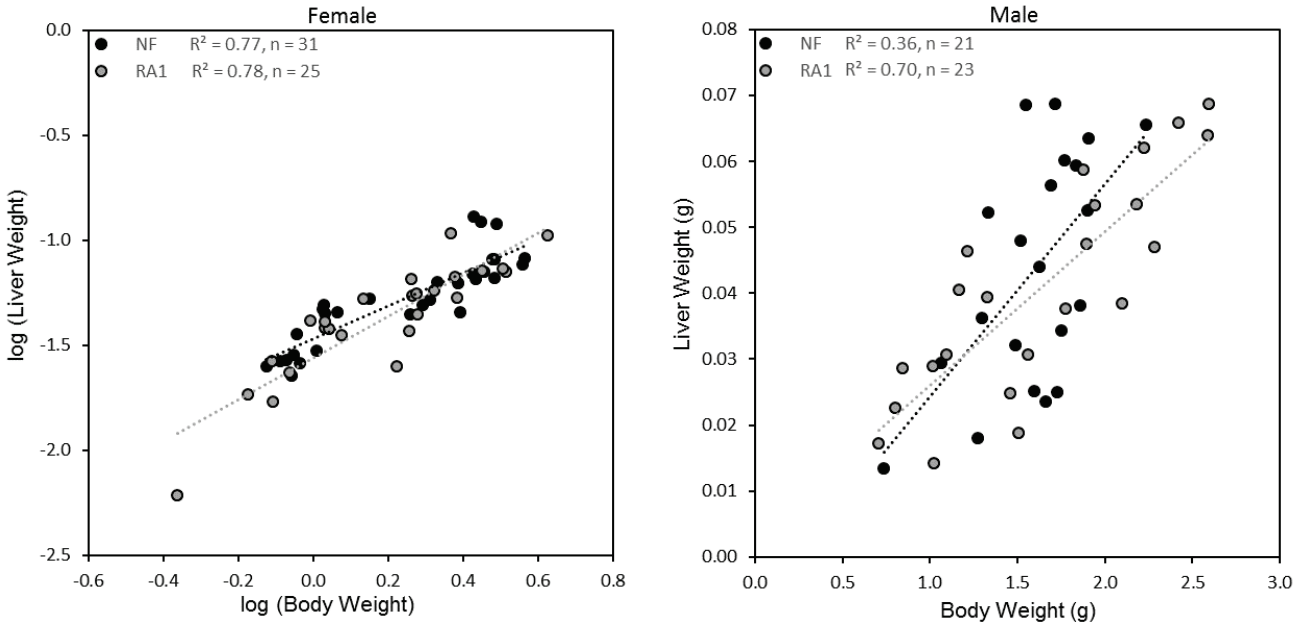
NF = Near-field Area; RA1 = Reference Area 1; n = sample size.

Figure 10.4-9: Fecundity of Female Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018

10.4.3.4 Condition

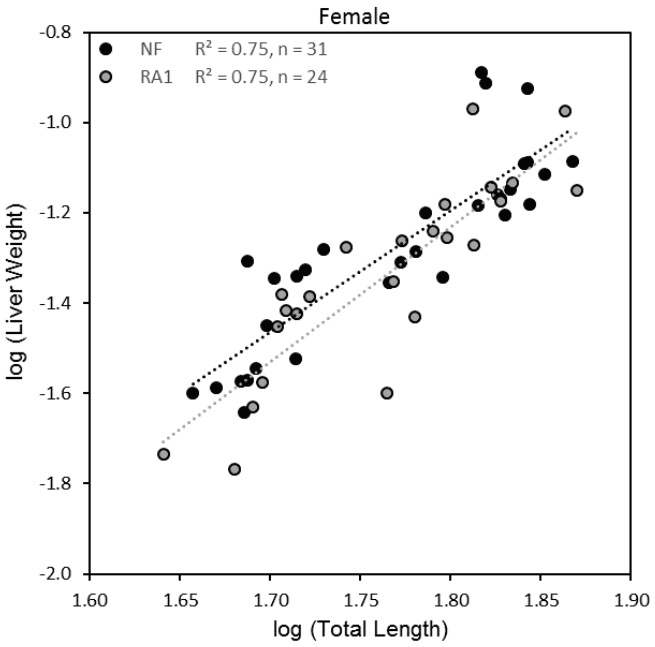
10.4.3.4.1 Condition Factor

Condition factor for lethally sampled female and male Threespine Stickleback from Meliadine Lake ranged from 0.54 to 1.09 and 0.69 to 1.13, respectively (Table 10.4-6). Relative body weight was significantly greater at the Near-field area relative to the Reference Area 1 for lethally sampled female fish (i.e., 6%; Table 10.4-7, Figure 10.4-10), but was not different for male fish. The magnitude of differences between the Near-field area and Reference Area 1 were below the CES of 10% for both female and male fish (Government of Canada 2018). Statistical power was sufficient to detect a 10% difference in relative body weight for both female and male Threespine Stickleback.



Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-7). Statistical outliers were excluded.
NF = Near-field Area; RA1 = Reference Area 1; g = gram; mm = millimetre; R^2 = coefficient of determination; n = sample size; log = log10 transformed data.

Figure 10.4-10: Body Weight Relative to Total Length for Female and Male Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018

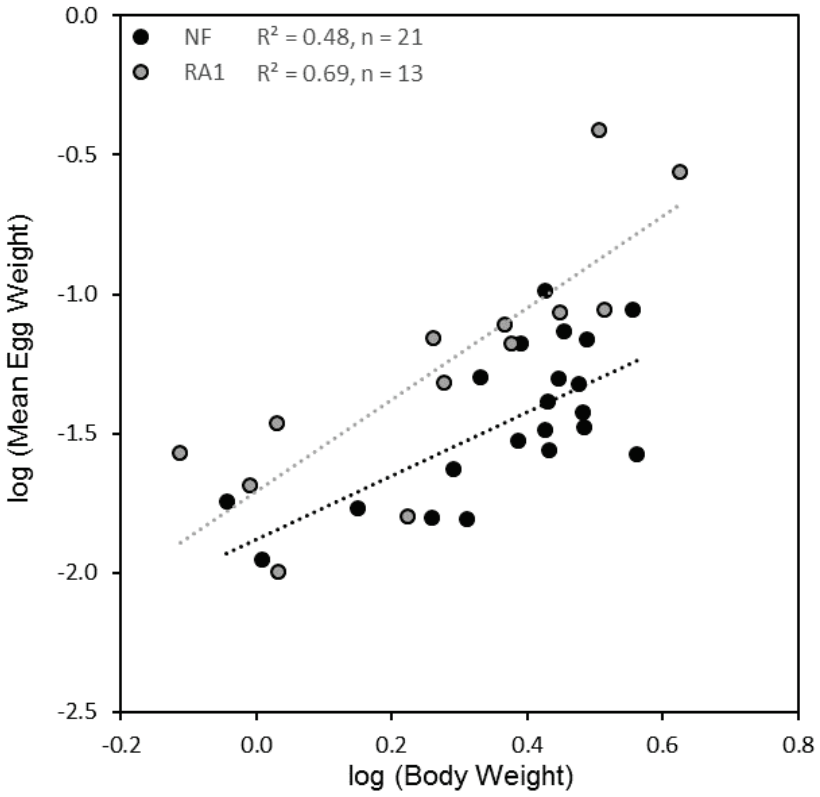


10.4.3.4.2 Relative Liver Size

The liver somatic index ranged from 1.41 to 4.85 for female Threespine Stickleback, and from 1.25 to 4.44 for males (Table 10.4-6). No significant differences were observed among sampling areas in relative liver size with body weight as a covariate for female or male fish (Table 10.4-7, Figure 10.4-11). Statistical power was sufficient to detect a difference of 25% for female relative liver size, while statistical power for male fish was 0.872. Relative liver size with total body length as the covariate was also examined as a supporting endpoint for energy storage in females, with no significant differences found between the two areas (Table 10.4-7, Figure 10.4-12).

Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-7).
NF = Near-field Area; RA1 = Reference Area 1; g = gram; R^2 = coefficient of determination; n = sample size; log = log10 transformed data.

Figure 10.4-11: Liver Weight Relative to Body Weight for Female and Male Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018



Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-7). Statistical outliers were excluded.
NF = Near-field Area; RA1 = Reference Area 1; g = gram; mm = millimetre; R^2 = coefficient of determination; n = sample size; log = log10 transformed data.

Figure 10.4-12: Liver Weight Relative to Total Length for Female Threespine Stickleback Lethally Sampled from Meliadine Lake, 2018

10.4.3.4.3 Relative Egg Size

Mean egg weight for female Threespine Stickleback sampled from Meliadine Lake ranged from 0.010 to 0.387 mg (Table 10.4-6, Figure 10.4-13). Relative egg size was examined as a supporting endpoint for energy storage in female fish and was 54% less in the Near-field area when compared to Reference Area 1 (Table 10.4-7).

Note: Data transformations consistent with those used in the statistical analysis (Table 10.4-7).
NF = Near-field Area; RA1 = Reference Area 1; g = gram; R^2 = coefficient of determination; n = sample size; log = log10 transformed data.

Figure 10.4-13: Egg Weight Relative to Body Weight for Female Threespine Stickleback Sampled from Meliadine Lake, 2018

10.4.3.5 Pathology

External abnormalities observed in Threespine Stickleback sampled from Meliadine Lake included frayed, clubbed, or marginated gills (i.e., gills with light, discoloured margin along tips of lamellae) and mild fin erosion (Table 10.4-9). The prevalence of external abnormalities was low, affecting 11% of the fish lethally sampled in Meliadine Lake, with a similar prevalence among sampling areas (Table 10.4-9). No body deformities or abnormalities of the eyes, skin, thymus, pseudobranchs, opercula or vent were observed.

Internal abnormalities observed in Threespine Stickleback sampled from Meliadine Lake included liver discoloration (i.e., “fatty” livers with a coffee cream colour) and a low incidence of swollen, mottled or granular kidneys (Table 10.4-11). Fatty livers are commonly observed in fish populations with an abundant food sources and are generally not indicative of disease (Kandemir and Polat 2007). Mesenteric fat content did not vary significantly among sampling areas (*P*=0.186; Table 10.4-10).

Table 10.4-9: Number of Lethally Sampled Threespine Stickleback with External and Internal Abnormalities, 2018

2	15	5
3	5	1

0 = None; 1 = <50%; 2 = 50%; 3 = >50%.

10.4.3.6 Parasites

Internal parasites were frequently observed in Threespine Stickleback sampled from Meliadine Lake and occurred in 61.9% of fish from the Near-field area and 71.1% of fish from Reference Area 1 (Table 10.4-11). Among lethally sampled fish, no Threespine Stickleback exhibited a low severity of parasitism (e.g., cysts), 62.5% of fish exhibited a moderate severity of parasitism in (e.g., tapeworms), and less than 0.1% exhibited a high severity of parasitism (e.g., multiple tapeworms). A significant difference was observed in the prevalence of parasites between adults and juveniles (P=0.016), with 60% of adults parasitized and 71% of juveniles parasitized. No significant differences were observed in the prevalence of parasites among sampling areas (P=0.248) or between males and females (P=0.129). Only one external parasite was observed in 2018, on a fish from the Near-field area.

A large tapeworm, suspected to be *Schistocephalus solidus,* was the most prevalent parasite among Threespine Stickleback captured in Meliadine Lake. The tapeworm infected 141 of the 216 fish sampled. The tapeworm *S. solidus* parasitizes small-bodied fish and fish-eating birds. Small-bodied fish, such as the Threespine Stickleback, become infected after consuming infected copepods and serve as an intermediate host for the parasite. The parasite develops in the body cavity of the fish until it is consumed by a fish-eating bird and is transmitted to its definitive host (Barber and Huntingford 1995). Potential definitive hosts for *S. solidus* in the Near-field area of Meliadine Lake are Sandhill crane (*Grus canadensis*), which were observed in the area during the time of sampling. On average, tapeworms accounted for 19.0% of body weight in infected fish.

The results of the statistical analysis for the lethal survey are presented for all fish (i.e., with and without parasites; Table 10.4-7) and non-parasitized fish only (Table 10.4-8). The results of the effect endpoint comparisons were similar with parasitized fish included and excluded from the analysis, with significant differences in female condition observed in both comparisons, and the magnitude of difference ranging from 6% to 9%, respectively (Table 10.4-7 and Table 10.4-8). When parasitized fish were excluded from the analysis, mean squared errors were typically smaller, due to reduced model variation; however, statistical power was also lower, due to a decreased sample sizes.

Table 10.4-11: Number of Parasitic Infections and Relative Severity Observed in Threespine Stickleback Collected from Meliadine Lake, 2018

Parasites	Severity	Near-field Area	Reference Area 1
External	0	569	300
	1	1	0
	2	0	0
	3	0	0
Internal	0	48	26
	1	0	0
	2	75	60
	3	3	4

Note: Values represent counts.

0 = no parasites; 1 = few parasites; 2 = moderate parasite infestation; 3 = numerous parasites.

10.5 Summary and Conclusions

Threespine Stickleback were the only species captured in sufficient numbers from the Near-field area and Reference Area 1 of Meliadine Lake to meet sample size requirements for the fish health component of the EEM program. Adult and juvenile Threespine Stickleback were abundant throughout shallow areas of Meliadine Lake (i.e., less than 3 m), and were susceptible to capture using minnow traps and dipnets. Young-of-the-year, however, were not captured or observed during sampling. This may have been due to YOY occupying habitats that were not effectively targeted by the sampling methods employed (e.g., residing within interstitial spaces of the rocky substrate, or at depths greater than 3 m), or YOY may not have been present due to the timing of sampling (i.e., during the spawning period).

Threespine Stickleback were spawning in Meliadine Lake during the August 2018 sampling period, based on the presence of male secondary sex characteristics and the occurrence of ripe and spent individuals of both sexes. Threespine Stickleback undergo multiple spawning events throughout the spring and summer months (Barrett and Munkittrick 2010); and exhibit extended spawning seasons for some populations (Wooton et al. 1978; Chellappa et al. 1989). Based on this information and observations herein, Threespine Stickleback likely spawn throughout the open-water period in Meliadine Lake. The extended spawning period likely contributed to the variability in reproductive endpoints observed during the 2018 sampling, with Threespine Stickleback documented at a variety of maturity stages within the dataset. However, because Threespine Stickleback likely spawn through the open-water period, it is unlikely the sensitivity of reproductive endpoints could be improved by altering sample timing. The current sample timing (i.e., August) conforms with EEM guidance when using Threespine Stickleback as a sentinel species (Barrett and Munkittrick 2010).

The majority of Threespine Stickleback captured were infected by a tapeworm that competes with the host for available resources and has been found to decrease the energy allocated to storage and spawning in Threespine Stickleback (Schultz et al. 2006; Rushbrook et al. 2007). The parasite was abundant at each of the areas sampled and, therefore, has the potential to confound the detection of changes in energy storage and reproductive endpoints that may result from the Mine. To evaluate the effect of parasitism on fish health endpoints, statistical analyses were completed with and without parasitized included (Table 10.4-7 and Table 10.4-8). The results of the two approaches were similar, and the emphasis of the analytical results were focused on analyses with parasitized fish included, due to better sample sizes and statistical power. The August 2018 sampling results also indicated that Threespine Stickleback infected with tapeworms reached sexual maturity at a similar size as uninfected fish.

Population structure for Threespine Stickleback varied among sampling areas, with larger individuals collected from the Near-field area when compared to Reference Area 1 (Table 10.5-1). Female Threespine Stickleback sampled from the Near-field area had greater relative body weight than individuals sampled from Reference Area 1, suggesting increased energy storage at the Near-field area; however, the magnitude of difference (i.e., 6%) was below the CES of 10% (Table 10.5-2). Supporting fish health endpoints for energy storage did not indicate the same; there were no significant differences observed in relative liver size, and relative egg size was significantly greater at Reference Area 1. Fish health endpoints were similar for male Threespine Stickleback among sampling areas (Table 10.5-2).

Power analyses of fish health endpoints indicated that sample sizes were sufficient to reliably detect differences that met or exceeded CESs for the majority of effect endpoints (i.e., power >0.9). However, a large degree of variability in age and gonad weights resulted in low statistical power for weight-at-age and relative gonad size comparisons for both sexes. Despite low power in these instances, the magnitudes of difference observed were below CES (Table 10.4-7).

In conclusion, Threespine Stickleback was the only species captured in sufficient abundance from Meliadine Lake to support sample sizes requirements of the EEM fish population survey. An effect was observed in the Near-field area for female condition, however the effect size of 6% was less than the CES of 10%. A similar response was not observed in supporting energy storage endpoints (i.e., relative liver weight and relative egg weight). Statistical analyses were confounded by a lack of a predictive relationship between age and body weight, and Threespine Stickleback being at a variety of reproductive stages at the time of sampling. These factors contributed to low statistical power for some endpoints. Threespine Stickleback were also commonly parasitized by tapeworms, which increased variability in the dataset; however, when infected fish were included in the statistical analysis, increased variability was offset by increased samples sizes resulting in a net increase in statistical power.

Table 10.5-1: Summary of Effect Endpoints for Threespine Stickleback Collected During the Population Survey, 2018

Parameter	CES	Magnitude of Difference	Comparison to Reference
Length-frequency distribution	(a)	20%(b)	↑
Weight-at-age	25%	-1%	-
Length-at-age	25%	-1%	-
Relative body weight	10%	1%	-

a) Length-frequency is an effect endpoint for non-lethal sampling in the EEM program; however, a CES has not been defined (Government of Canada 2018).

b) Magnitude based on maximum percent difference between groups in cumulative frequency distribution.

CES = critical effect size; NF = Near-field area; RA1 = Reference Area 1; ↑ = endpoint significantly greater at Near-field area compared to Reference Area 1; - = not significantly different.

Table 10.5-2: Summary of Effect Endpoints for Threespine Stickleback Sampled During the Lethal Survey, 2018

Sex	Parameter	CES	Magnitude of Difference	Comparison to Reference
Female	Age(a)	25%	0%	-
	Weight-at-age	25%	15%	-
	Relative gonad size	25%	4%	-
	Relative body weight	10%	6%	↑
	Relative liver size	25%	10%	-
Male	Age(a)	25%	7%	-
	Weight-at-age	25%	-18%	-
	Relative gonad size	25%	-1%	-
	Relative body weight	10%	-2%	-
	Relative liver size	25%	9%	-

a) Length was used as a surrogate for age (Environment Canada 2012).

CES = critical effect size; NF = Near-field area; RA1 = Reference Area 1 ; % = percent; ↑ = endpoint significantly greater at Near-field area compared to Reference Area 1; - = not significantly different.

10.6 Recommendations

No recommendations are provided for changes to fish health monitoring under the EEM.

11.0 PLANKTON TARGETED STUDY

Plankton monitoring was conducted as a targeted study to evaluate if plankton will be a useful long-term monitoring tool for the Mine. Prior to the 2018 sampling program, the plankton study included sampling and analysis of depth-integrated nutrients, chlorophyll *a*, phytoplankton, and zooplankton over three years in Meliadine Lake (2015, 2016, and 2017) and two years in the Peninsula Lakes[11] (2015 and 2016). Based on the data collected, it was determined that the phytoplankton dataset (i.e., chlorophyll *a*, phytoplankton abundance, biomass, and composition of major taxonomic groups, along with supporting nutrient data collection) should be carried forward to future years for Meliadine Lake to further evaluate its usefulness as a monitoring tool (Golder 2018c). Due to high variability between seasonal sampling events, it was recommended that phytoplankton sampling during only a single season be carried forward for future monitoring years. August (summer) was chosen as the most useful target month for analysis of spatial trends due to lower variability in phytoplankton monitoring endpoints among years in August (Golder 2018c). Additionally, due to high variability in the zooplankton dataset as a whole, it was recommended that zooplankton not be carried forward as a monitoring tool for Meliadine Lake. As a result, only phytoplankton sampling during the summer season was carried forward for 2018 to evaluate potential changes in key monitoring endpoints (abundance, biomass, community composition) and to provide an indication of potential changes to trophic status in the lake.

This report section provides a summary of data collected during the summer 2018 phytoplankton sampling program in Meliadine Lake, with a comparison against data collected during summer sampling events during the pre-construction and construction phase of the Mine (2015 through 2017). Data collected during spring and fall sampling events during the pre-construction and construction phase is not reported herein, because seasonal variability in plankton community characteristics does not allow valid year-to-year comparisons of data collected in different months during the open-water season. Data are also provided for the Peninsula Lakes for chlorophyll *a* samples collected in 2018 and compared against data collected during previous monitoring years. Statistical analyses of spatial variability in the phytoplankton community of Meliadine Lake are presented, along with analysis of nutrient concentrations in relation to effluent discharges in the Near-field area, and analysis of potential effects on plankton abundance, distribution and community composition.

11.1 Methods

11.1.1 Sampling Design

The plankton sampling program in 2018 was based on the AEMP Design Plan (Golder 2016a). The sampling program consisted of a single sampling event during open-water conditions in August (summer) targeting the exposure and reference areas of Meliadine Lake, with additional sampling for chlorophyll *a* in the Peninsula Lakes. The 2015 program specifically targeted the exposure areas of Meliadine Lake, with seasonal sampling during three sampling events, July (spring), August (summer), and September (fall), and additional sampling in the Peninsula Lakes. The 2016 program targeted both exposure and reference areas of Meliadine Lake, with sampling during all three seasons and additional sampling in the Peninsula Lakes. The 2017 program targeted the exposure and reference areas of Meliadine Lake during all three seasons and included only chlorophyll *a* sampling in the Peninsula Lakes.

Sampling was conducted in conjunction with the water quality sampling program in August (summer) in 2015 through 2018 (Table 11.1-1; Figure 1-3). A total of five stations were sampled in each of the Near-field (NF) and Mid-field (MF) exposure areas of Meliadine Lake in all years, and in three reference areas of Meliadine Lake

[11] Chlorophyll *a* was also sampled at the peninsula lakes in 2017.

in 2016, 2017 and 2018. New stations were added to replace historical stations in the Near-field and Mid-field exposure areas in 2018 as described in Section 6.2.1. Plankton samples in Meliadine Lake in all years were collected from a target water depth of 8 to 10 m.

Three stations in each of the Peninsula Lakes (A8, B7, and D7) were sampled in 2015 to 2018 from a target water depth of 1.5 to 2.5 m (Figure 1-3). Not all stations were consistently sampled during each field program due to delays caused by inclement weather conditions (e.g., fog, high winds).

The plankton sampling program consisted of the following components:

- measurements of total water depth (m) and Secchi depth (m)
- collection of depth-integrated water samples for nutrient analysis (soluble reactive silica [SRSi], TN, and TP) from the euphotic zone (Meliadine Lake only)
- collection of chlorophyll *a* samples
- collection of phytoplankton samples

NAD = North American Datum; Chl = indicates that chlorophyll *a* samples were collected; DIN = indicates that depth-integrated nutrient samples were collected; P = phytoplankton samples were collected; - = the site was not included in the sampling plan for a particular field program, or was not sampled due to weather, environment, or schedule limitations; QC-dup = indicates that a quality control duplicate sample was collected. (a) DIN QC-dup samples. (b) Phytoplankton QC-dup samples.

11.1.2 Field Methods

11.1.2.1 Supporting Environmental Variables, Nutrients, and Chlorophyll a

During the time of sampling, local weather data (i.e., air temperature, wind conditions, and rainfall) were collected. At each sampling station, water depth and physicochemical measurements were recorded. Total depth of the water column was measured either by using a sounding line or a boat-mounted sonar unit. In situ physicochemical measurements of specific conductivity, DO, pH, and water temperature were collected at each lake station using a submersible multi-sensor probe system (Hanna HI-9828 multiprobe). In situ physicochemical measurements were taken just below the surface and every 1 m thereafter throughout the water column, ending at 1 m above the lake bed. Secchi depth was measured using a 20 cm diameter Secchi disk at each station; this information was used to estimate the euphotic zone depth for depth-integrated sample collection.

Depth-integrated composite samples were collected at all Meliadine Lake stations for analysis of chlorophyll *a* and nutrient concentrations. Given the shallow nature of the Peninsula Lakes, depth-integrated samples were not collected at these locations. Instead, discrete samples at mid-column depths were collected for analysis of chlorophyll *a* and nutrients.

The euphotic zone is defined as the extent of the water column that is exposed to sufficient sunlight for photosynthesis to occur (typically to a depth in the water column where 1% of the surface irradiance is measured). While in the field, the euphotic zone was calculated as two times the Secchi depth (Koenings and Edmundson 1991; Alberta Environment [AENV 2006]).

Once the euphotic zone depth was determined, a Kemmerer sampler was used to collect discrete water samples starting at the surface, and continuing every 2 m through the extent of the euphotic zone. If the total water column depth was less than two times the Secchi depth, a water sample was collected every 2 m from the surface to 2 m above the lake bed.

Equal volumes of water from each discrete depth were combined into a large, clean bucket to create a composite, depth-integrated sample. From this composite sample, single subsamples were collected for nutrient analysis, triplicate subsamples were collected for chlorophyll *a* analysis, and a single subsample was taken for phytoplankton community analysis as described in Section 11.1.2.2.

Sample bottles for nutrient analysis were provided by ALS (Edmonton), which is an analytical laboratory accredited by CALA. Water samples were processed (i.e., filtered and/or preserved as required, and refrigerated) at site according to the instructions provided by ALS. Water samples requiring filtration were filtered through a 0.45-µm Millipore filter in a Nalgene filter tower, using a vacuum pump, before being preserved with laboratory-provided preservative based on the required analysis. Water samples were kept cool through refrigeration before shipping, and during shipping by adding ice-packs to the coolers. Samples were shipped to ALS as soon as possible after sample collection and processing. Samples were analyzed for TN, dissolved nitrogen, total Kjeldahl nitrogen (TKN), dissolved Kjeldahl nitrogen, total ammonia, nitrate, nitrite, TP, dissolved phosphorus, dissolved orthophosphate, and SRSi.

Water samples for chlorophyll *a* analysis were collected at each station during all field programs. Measurement of chlorophyll *a* concentration in water is a standard method to estimate phytoplankton biomass. Chlorophyll *a* is the primary photosynthetic pigment in phytoplankton and is frequently used as an indicator of phytoplankton biomass and primary production. Triplicate water samples for chlorophyll *a* analysis were filtered through a 47 mm diameter Whatman glass fiber type-C filter (nominal pore size: 1.2 µm) in a glass filter tower, using a vacuum pump under low light conditions to prevent photo-shock in the algal cells. A volume of 300 to 500 millilitres (mL) of water was filtered for each chlorophyll *a* sample. The filters were folded in half, placed in a pre-labelled Petri dish, wrapped with aluminum foil, and frozen. Frozen filters were submitted to the Biogeochemical Analytical Service Laboratory at the University of Alberta, Edmonton, Alberta, for spectrophotometric analysis of chlorophyll *a*.

11.1.2.2 Phytoplankton Collection

A single water sample for phytoplankton analysis (either depth-integrated [Meliadine Lake stations] or discrete samples [peninsula lake stations]) was used to fill a 250-mL amber Nalgene bottle. Phytoplankton samples were preserved with approximately 4 mL of Lugol's solution. Samples were sealed, labelled, and stored in the dark (inside coolers) for transportation to Plankton R Us, Winnipeg, Manitoba, for taxonomic identification to the lowest practical taxonomic level, and abundance and biomass estimates.

11.1.3 Laboratory Methods

Laboratory methods for nutrient analysis, including the laboratory test code, laboratory test description and analytical method references are further described in the laboratory certificate of analysis (Attachment A). Laboratory procedures for chlorophyll *a* analysis include extraction, filtration and spectrophotometric analysis. Chlorophyll concentrations were calculated using the absorbencies at specified wavelengths and the original extraction and filtration volumes. Laboratory methods for phytoplankton enumeration, identification, and QA/QC procedures are further described in Appendix 11A.

11.1.4 Data Analysis

11.1.4.1 Depth-Integrated Samples

Descriptive statistics (i.e., minimum, median, maximum, mean, standard error, standard deviation) for depth-integrated nutrients and chlorophyll *a* were calculated to evaluate spatial and temporal data collected in Meliadine Lake. Where concentrations were below the DL, the concentration was set to half the value of the DL for calculating summary statistics. The percentage of non-detect samples in the data set was reported for each parameter.

11.1.4.2 Trophic Status

Trophic status is a useful means of classifying lakes and can be used as an indicator to describe the productivity of a system. Trophic status of a waterbody can be evaluated by examining the concentrations of chlorophyll *a*, nutrients, and water transparency. Chlorophyll *a* is the primary photosynthetic pigment in phytoplankton, and is often used as a surrogate measure of phytoplankton biomass and production in lakes (Franklin et al. 2012). The essential nutrients necessary for phytoplankton growth are nitrogen, phosphorus, carbon, and for some groups (e.g., diatoms), silica. The primary nutrient that often limits phytoplankton growth in lakes is phosphorus (Schindler 1974); therefore, phosphorus is often used to establish the trophic status of lakes. Secchi depth (a measure of water transparency) can be used as a coarse surrogate of phytoplankton biomass, because in many waterbodies, Secchi depth is inversely related to phytoplankton biomass (Dodds and Whiles 2010); therefore, Secchi depth is also considered when evaluating trophic status.

The three main classes of trophic status are the following:

- oligotrophic (nutrient-poor, unproductive systems)
- mesotrophic (moderately productive systems)
- eutrophic (nutrient-rich, highly productive systems)

The trophic status of Meliadine Lake was evaluated by examining the nutrient data (TP), chlorophyll *a* concentrations, and water transparency (Secchi depth). The trophic status was determined using the Vollenweider (1968) trophic classification scheme for lakes (Table 11.1-2), the CCME (2004) trigger ranges (Table 11.1-3), and the Carlson (1977) Trophic State Index (TSI; Table 11.1-4). Of the three commonly used variables to calculate TSI, chlorophyll *a* is considered the best predictor of the overall trophic status of lakes (Carlson and Simpson 1996). As a result, the overall trophic status of Meliadine Lake was determined using the TSI value calculated based on chlorophyll *a* concentrations, and this classification was supported by TSI values calculated based on nutrient availability (TP) and water transparency.

Table 11.1-2: General Trophic Classification of Lakes

Trophic Status	Total Phosphorus (mg/L)		Chlorophyll *a* (µg/L)		Secchi Depth (m)	
	Mean	Range	Mean	Range	Mean	Range
Oligotrophic	0.008	0.003 to 0.018	1.7	0.3 to 4.5	9.9	5.4 to 28.3
Mesotrophic	0.027	0.011 to 0.096	4.7	3.0 to 11.0	4.2	1.5 to 8.1
Eutrophic	0.084	0.016 to 0.386	14.3	3.0 to 78.0	2.5	0.8 to 7.0

Source: Vollenweider 1968.

mg/L = milligrams per litre; µg/L = micrograms per litre.

Table 11.1-3: Trophic Classification of Canadian Lakes Based on Total Phosphorus Trigger Ranges

Trophic Status	Total Phosphorus (mg/L)
Ultra-oligotrophic (very nutrient-poor)	<0.004
Oligotrophic (nutrient-poor)	0.004 to 0.010
Mesotrophic (containing a moderate level of nutrients)	0.010 to 0.020
Meso-eutrophic (containing moderate to high levels of nutrients)	0.020 to 0.035
Eutrophic (nutrient-rich)	0.035 to 0.100
Hyper-eutrophic (very nutrient-rich)	>0.100

Sources: CCME 2004; Environment Canada 2004.

mg/L = milligrams per litre; <= less than; >= greater than.

The TSI is a numerical trophic state index for lakes that classifies lakes on a scale of 0 to 100 (Carlson 1977). The index number is calculated from Secchi depth, chlorophyll *a*, and TP using the following equations (Carlson 1977):

$$TSI\ (TP) = 10\left(6 - \frac{\ln {}^{48}/_{TP}}{\ln 2}\right) \quad \text{Equation 1}$$

$$TSI\ (Chl) = 10\left(6 - \frac{2.04 - 0.68 \ln Chl}{\ln 2}\right) \quad \text{Equation 2}$$

$$TSI\ (Secchi) = 10\left(6 - \frac{\ln Secchi}{\ln 2}\right) \quad \text{Equation 3}$$

where:

- TSI = trophic state index
- TP = total phosphorus
- ln = the natural log
- Chl = chlorophyll *a*
- Secchi = Secchi depth

Values calculated using these equations are multiplied by 10 to give the scale a range of 0 to 100. The numerical scales for each of the three TSIs are presented in Table 11.1-4.

Table 11.1-4: Comparison of Trophic State Index Classification and General Trophic Classification of Lakes

Trophic State Index	Total Phosphorus (mg/L)	Chlorophyll *a* (µg/L)	Secchi Depth (m)	General Trophic Classification
<30 to 40	0 to 0.012	0 to 2.6	>8.0 to 4	Oligotrophic
40 to 50	0.012 to 0.024	2.6 to 20	4 to 2	Mesotrophic
50 to 70	0.024 to 0.096	20 to 56	2 to 0.5	Eutrophic
70 to 100+	0.096 to 0.38+	56 to 155+	0.5 to <0.25	Hyper-eutrophic

Source: Carlson 1977.

mg/L = milligrams per litre; µg/L = micrograms per litre; <= less than; >= greater than.

11.1.4.3 Phytoplankton

Phytoplankton data were analyzed separately, but the same approach was used for both datasets. The following variables were calculated for each sample:

- total abundance (abundance by cell density as cells per litre [cells/L])
- total biomass (biomass as milligrams per cubic metre [mg/m^3])
- total taxonomic richness (richness as number of taxa [no. of taxa] at a station)
- relative abundances (as percentages) of major taxonomic groups
- relative biomass (as percentages) of major taxonomic groups

Abundance and biomass data were divided into major taxonomic groups. Phytoplankton groups were Cyanobacteria, Chlorophyceae (chlorophytes), Chrysophyceae (chrysophytes), Cryptophyceae (cryptophytes), Dinophyceae (dinoflagellates), Bacillariophyceae (diatoms), and Euglenophyceae (euglenoids).

Mean total abundance and mean total biomass were calculated for each sampling area (e.g., Near-field area) and plotted as bar graphs showing the mean and standard error (SE). Mean taxonomic richness at the species level was summarized for each area and plotted as a bar graph. Taxonomic richness provides an indication of the diversity at a station; higher richness values typically indicate more healthy and balanced communities. For stations where duplicate QC samples were collected, total taxonomic richness was calculated as the average richness of the two duplicate samples.

11.1.4.4 Spatial and Temporal Trends

Nutrient concentrations, chlorophyll *a,* and plankton community variables were compared visually among areas and years to explore inter-annual and spatial trends. The following variables were plotted for each area and sampling event:

- mean total nitrogen and total phosphorus concentrations
- mean chlorophyll *a* concentration
- mean total phytoplankton abundance and biomass
- total nitrogen, total phosphorus, chlorophyll a concentrations, and total phytoplankton biomass plotted for each station in the Near-field area

- mean total phytoplankton richness
- mean relative proportion accounted for by each major taxonomic group, based on abundance and biomass, plotted as stacked bars (for phytoplankton)

Scatter plots were used to evaluate the strength of the relationship between chlorophyll *a* concentrations and phytoplankton biomass, and to evaluate the spatial variability of each variable against concentrations of depth-integrated nutrients.

11.1.4.5 Statistical Analysis

The objective of the statistical comparisons of plankton data collected in Meliadine Lake was to compare data collected from the Near-field area (MEL-01) with the Mid-field exposure area (MEL-02) and the three reference areas (MEL-03, MEL-04, and MEL-05). Descriptive statistics (i.e., minimum, maximum, median, mean, standard deviation, standard error) were calculated to compare and evaluate spatial and temporal data collected in Meliadine Lake. One-way ANOVA or the Kruskal-Wallis test was used to compare plankton endpoints (e.g., abundance, biomass, richness) and nutrient and chlorophyll *a* concentrations among sampling areas. Multivariate analysis (nMDS) was also used to investigate differences in community structure among areas. Statistical tests were performed using SYSTAT 13.1 for Windows (Systat Software 2009) or PRIMER version 7.0.13 software (Quest Research 2017).

Statistical Analysis

Univariate statistical comparisons were used to identify differences in plankton community endpoints among areas. A significance level (α) of 0.1 was used for ANOVA models, and an α of 0.05 was used for testing statistical assumptions (i.e., normality and homogeneity of variances). Prior to conducting ANOVAs, the assumptions of parametric statistical tests were verified using the Shapiro-Wilk test for normality and Levene's test for homogeneity of variances on untransformed and log-transformed data. Data that violated assumptions of normality or equality of variances were transformed and the effectiveness of the transformations was verified. If the assumptions of the ANOVA were not met, the non-parametric equivalent of ANOVA (i.e., Kruskal-Wallis test) was used.

Mean values for each parameter from the exposure and reference areas were initially compared to one another in an overall ANOVA. Tukey's honestly significant difference (HSD) method was used for multiple unplanned (i.e., *a posteriori*) comparisons following the overall ANOVA. This test adopts a conservative approach by employing experiment-wise error rates for the Type I error (Day and Quinn 1989). Therefore, a *P* value of 0.1 was used for these tests.

For variables that did not meet parametric test assumptions (e.g., chlorophyll *a*), the Kruskal-Wallis test was used to test for differences among sampling areas. Kruskal-Wallis tests were considered significant at $P < 0.1$. The multiple-comparison procedure controls the experiment wise error rates for the Type I error and, therefore, holds the probability of correctly finding no difference at 1–α. However, under this scenario, the task of correctly detecting differences that are significant is more difficult (Daniel 1990). To maintain a sufficiently small Type II error (β) with the multiple comparisons, a larger α (or *P*-value) was used. The contrasts were tested at $P = 0.1$, and the multiple comparisons were conducted with $P = 0.15$.

Multivariate Analysis

Non-metric multidimensional scaling (nMDS), a multivariate ordination technique, was used to investigate differences in plankton community structure among areas in August 2016, 2017 and 2018. nMDS takes a pair-wise matrix of similarities among cases calculated from the original taxonomic data (biomass by station-year),

and then reduces it to a small number (typically two) of underlying dimensions of variation among cases. In this way, nMDS can visually simplify a multidimensional taxonomic data-set in two or three dimensions that capture the major patterns of variation in community composition.

The plankton taxonomic data were analyzed at the LTL. A square root transformation was applied to improve the separation of the data among stations on the nMDS plots. Transforming the data also reduced weighting of the analysis by the most abundant taxa. The appropriate data transformation was determined by examining “shade plots” created in PRIMER. Alternative data transformations were also explored; however, stronger transformations (i.e., fourth-root and Log x+1 transformations), heavily down-weighted the data, and were deemed unsuitable for this analysis.

Following the data transformation, a Bray-Curtis resemblance matrix was generated, and the nMDS procedure was applied to this matrix. Using rank order information, nMDS determined the relative positions of stations in two dimensions based on community composition. Goodness-of-fit was determined by examining the Shepard diagrams as well as the stress values, which were calculated from the deviations in the Shepard diagrams. Two dimensions were selected for each nMDS after confirming that the final stress value of the two-dimensional configuration was sufficiently low (less than 0.2; Clarke 1993). Points that fall close together on the nMDS ordination plot represent samples with similar community composition; points that are far apart from each other represent samples with dissimilar community composition.

11.1.4.6 Normal Range

The methods for defining the normal range for the Plankton Targeted Study followed the methods described in Section 6.2.4.2. Provisional normal ranges for plankton were calculated for Meliadine Lake from pooled reference area (MEL-03, MEL-04, and MEL-05) data collected during the AEMP between 2016 and 2018. Near-field and Mid-field data collected between 2015 and 2017 were not included in the normal range calculation, because water quality and chlorophyll *a* data collected during these years suggested a slight effect on primary productivity in the exposure areas in Meliadine Lake, potentially as a result of treated sewage discharges from the exploration camp.

The normal ranges provided in this report are considered provisional due to the limited sample sizes used in the calculations. The normal range is intended to estimate the range of natural spatial and temporal variability, and the more reference data incorporated into the calculation, the more accurate the estimate becomes. These normal ranges may be re-defined in future reports to allow for the inclusion of additional monitoring data in the reference areas.

11.2 Quality Assurance/Quality Assurance

11.2.1 Methods

QA components of the program included the use of trained personnel and an accredited analytical laboratory; QC components included assessments of duplicate samples for DIN and phytoplankton. Phytoplankton samples were collected from each sampling station using consistent sampling techniques for each sample. Replicates were collected immediately after one another and were preserved using approximately the same concentration of Lugol's solution. The taxonomic laboratory identified organisms down to the lowest practical taxonomic level.

Chlorophyll *a* samples were collected from each sampling station using consistent sampling techniques for each sample. Replicates were collected immediately after one another and were kept cool and dark until filtered and frozen prior to sample shipment.

Further details regarding the QA/QC practices applied during this study and detailed results of the QA/QC measures implemented by the taxonomic and analytical laboratories are reported in Appendix 11A. A summary of the key QC findings is provided in Section 11.2.2 below.

11.2.2 Results

Key QC findings for the 2018 plankton monitoring programs are as follows:

- Nutrients and Chlorophyll *a*:
  - A total of 12% of paired concentrations in duplicate DIN samples had a RPD greater than 20%. Each of the three RPD exceedances came from duplicate samples collected at MEL-01-09 in August 2018, where RPDs for concentrations of TKN, TN and TP exceeded 20%. All RPDs for the other set of DIN duplicate samples collected at MEL-02-01 in 2018 were below 20%.
  - Concentrations of dissolved parameters were generally lower than corresponding total concentrations for the DIN samples. Dissolved concentrations were higher than total concentrations for 4.4% of comparisons.
  - RPDs for total phosphorus concentrations in 2018 were below 20% in all samples.
- Phytoplankton:
  - The dominant taxon was consistent between duplicate samples for phytoplankton biomass and abundance.
  - RPDs for total phytoplankton biomass and abundance were below 50% for all duplicates.
  - RPDs above 50% were observed in the majority of duplicates for major phytoplankton taxonomic groups; however, graphical presentation of the relative abundances of major phytoplankton groups showed that variation between duplicates was actually low and that the proportions of major groups were similar between duplicates.

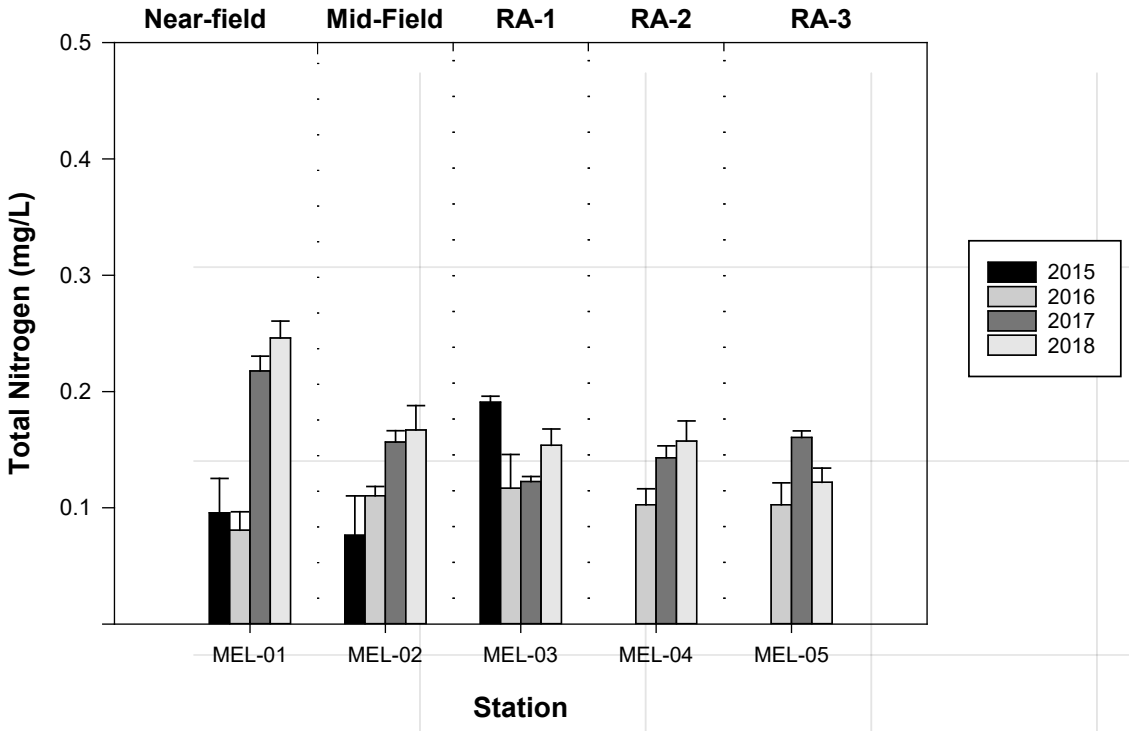
Differences between original and QC samples were deemed minor, and within the range of variability expected in plankton data. Based on this assessment, the plankton monitoring data are considered adequate to meet the needs of the AEMP for the Mine.

11.3 Results and Discussion

The results of the phytoplankton sampling programs completed in Meliadine Lake in 2015 to 2018 are summarized in Sections 11.3.1 to 11.3.3. Chlorophyll *a* sampling results in the peninsula lake are summarized in Section 11.4. Results from previous sampling programs in the Peninsula Lakes in 2015 through 2017 were presented in 2017 AEMP Annual Report (Golder 2018c). Detailed results are provided in the following appendices:

- Appendix 11B: Depth-Integrated Nutrients and Chlorophyll *a*
- Appendix 11C: Trophic Status
- Appendix 11D: Phytoplankton Community Results

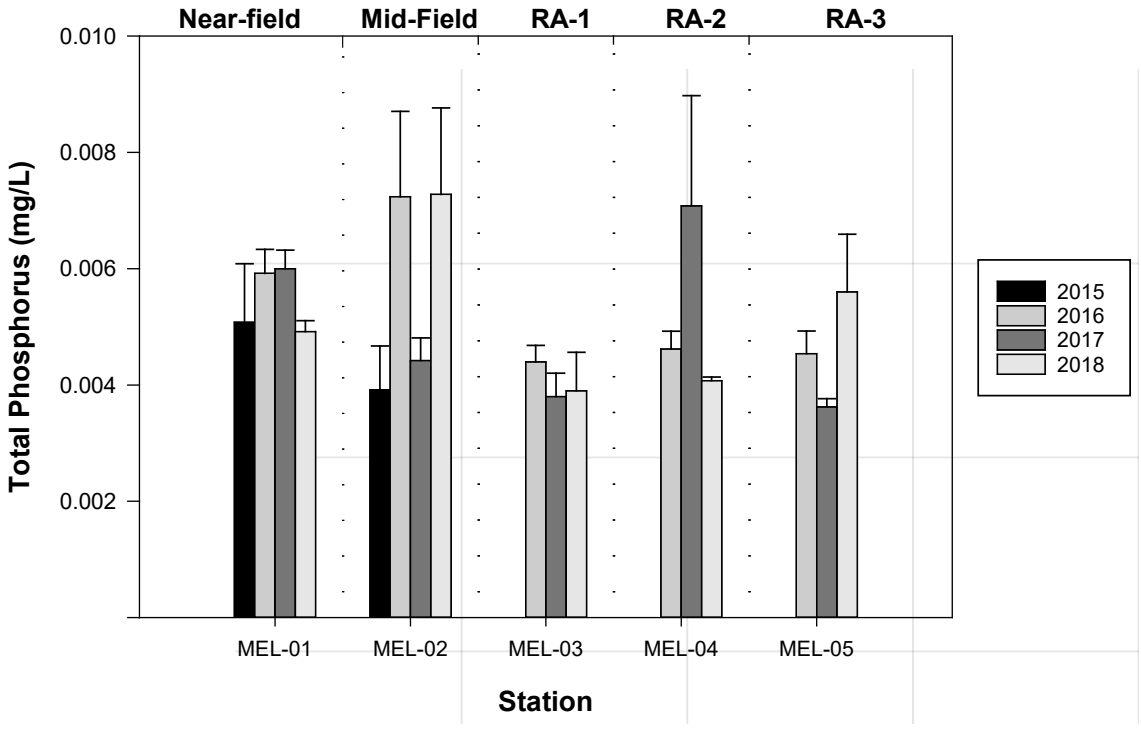
11.3.1 Depth-Integrated Nutrients and Chlorophyll *a*



Depth-integrated nutrient and chlorophyll *a* results for samples collected from Meliadine Lake in 2015 to 2018 are provided in Appendix 11B. Summary statistics (count, minimum, median, mean, maximum, standard error, standard deviation) for depth-integrated nutrients are provided in Tables 11B-1 to 11B-3. Summary statistics for chlorophyll *a* are provided in Table 11B-4. Raw data for depth-integrated nutrients and chlorophyll *a* are provided in Tables 11B-5 and 11B-6 respectively.

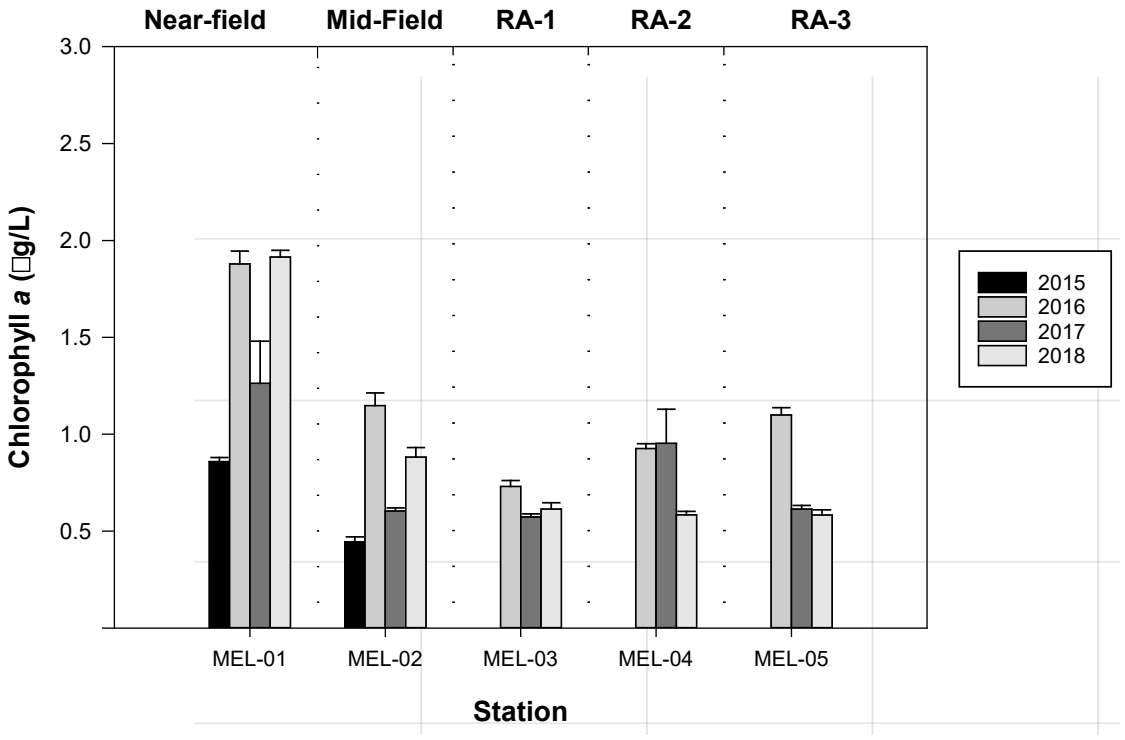
Concentrations of most depth-integrated nutrients were generally low in 2018 and consistent with concentrations observed in previous years. The mean concentration of TN in the Near-field area was 0.25 mg-N/L in 2018, which is slightly higher than in previous years, when mean TN concentrations ranged between 0.08 and 0.22 mg-N/L (Figure 11.3-1). Concentrations of TN ranged between a mean concentration of 0.12 mg-N/L (MEL-05) and 0.17 mg-N/L (MEL-02) in the Mid-field and reference areas in 2018, compared with a range of 0.08 to 0.19 mg-N/L in previous years.

Concentrations of TP in 2018 were generally above DLs but were low and consistent with TP concentrations observed in 2015, 2016 and 2017 (Figure 11.3-2). Some variability in TP concentrations was observed across sampling areas in 2018, but no consistent trends were apparent. The mean concentration of TP in the Near-field area was 0.0049 mg-P/L which was consistent with TP concentrations in previous years, which ranged between 0.0051 and 0.0060 mg-P/L. Concentrations of TP in the Mid-field exposure and reference areas ranged from a mean concentration of 0.0039 mg-P/L (MEL-03) to 0.0073 mg-P/L (MEL-02) in 2018 compared with a range of 0.0036 to 0.0072 mg-P/L in previous years.



Concentrations of nitrate, nitrite, ammonia, and orthophosphate were below DLs in the majority of samples collected in 2018, consistent with previous years. Minor spatial differences were observed in silica concentrations in Meliadine Lake in 2018, with slightly higher mean concentration of silica in the Near-field area (0.36 mg/L) than in the Mid-field area (0.31 mg/L) and the reference areas (0.24 mg/L); however, the observed difference in silica concentrations was less pronounced than observed in 2017.

Chlorophyll *a* concentrations followed a similar spatial trend in 2018 as observed in previous years, with higher concentrations in the Near-field area than the Mid-field and reference areas (Figure 11.3-3). Mean chlorophyll *a* concentration in the Near-field area in 2018 was 1.9 ± 0.03 µg/L compared to 0.9 ± 0.05 µg/L in the Mid-field area, and 0.6 ± 0.03 µg/L in the reference areas. Chlorophyll *a* concentrations in the Near-field area were higher in 2018 than in 2017 (1.3 ± 0.2 µg/L) and 2015 (0.9 ± 0.2 µg/L) but consistent with concentrations observed in 2016 (1.9 ± 0.07 µg/L).



Notes: Mean values are presented for each area. Error bars represent standard error (SE). RA = Reference Area; mg/L = milligrams per litre.

11.3.1.1 Statistical Comparisons of Nutrients and Chlorophyll a

Statistical comparisons of depth-integrated nutrient and chlorophyll *a* concentrations from samples collected in August 2016, 2017 and 2018 were made to evaluate spatial variability among the five areas of Meliadine Lake. Data collected in August 2015 was omitted from statistical comparisons due to lack of sampling in the reference areas. Differences observed in the concentrations of total nitrogen, total phosphorus, and chlorophyll *a* in August 2016, 2017 and 2018 in Meliadine Lake are summarized below:

- In 2016, total nitrogen concentrations were not significantly different among any of the five sampling areas ($P = 0.695$) (Table 11.3-1). In 2017, total nitrogen was significantly higher among the areas overall ($P < 0.001$), which was mostly attributed to significant differences between the Near-field and the Mid-field areas and reference areas. Significant differences in nitrogen concentrations were also observed between the Mid-field area and RA-1, and between RA-1 and RA-3 in 2017. In 2018, a similar trend was observed with significant differences in TN overall ($P = 0.041$) and between the Near-field area and all other areas.
- Total phosphorus concentrations varied significantly overall among areas in 2016 ($P = 0.051$), 2017 ($P = 0.054$) and 2018 ($P = 0.056$); however, few significant differences were observed in pairwise comparisons between areas, and there was no clear spatial trend of differences between the Near-field area and other areas (Table 11.3-1). Significant differences were observed between the Mid-field area and RA-1 in 2016, between RA-2 and RA-3 in 2017, and between the Near-field area and RA-2, the Mid-field area and RA-1, and the Mid-field area and RA-2 in 2018.

- Chlorophyll *a* concentrations were significantly different among areas in all years (P <0.001) (Table 11.3-1). Pairwise comparisons revealed that chlorophyll *a* concentrations were significantly different between the Near-field area and all other areas in 2016, 2017 and 2018 (P <0.001). In 2016, significant differences were observed among all other areas except one, while in 2017 there were no significant differences among the Mid-field area and reference areas. In 2018, there were significant differences in chlorophyll *a* concentrations between the Mid-field area and the reference areas but not among the reference areas.

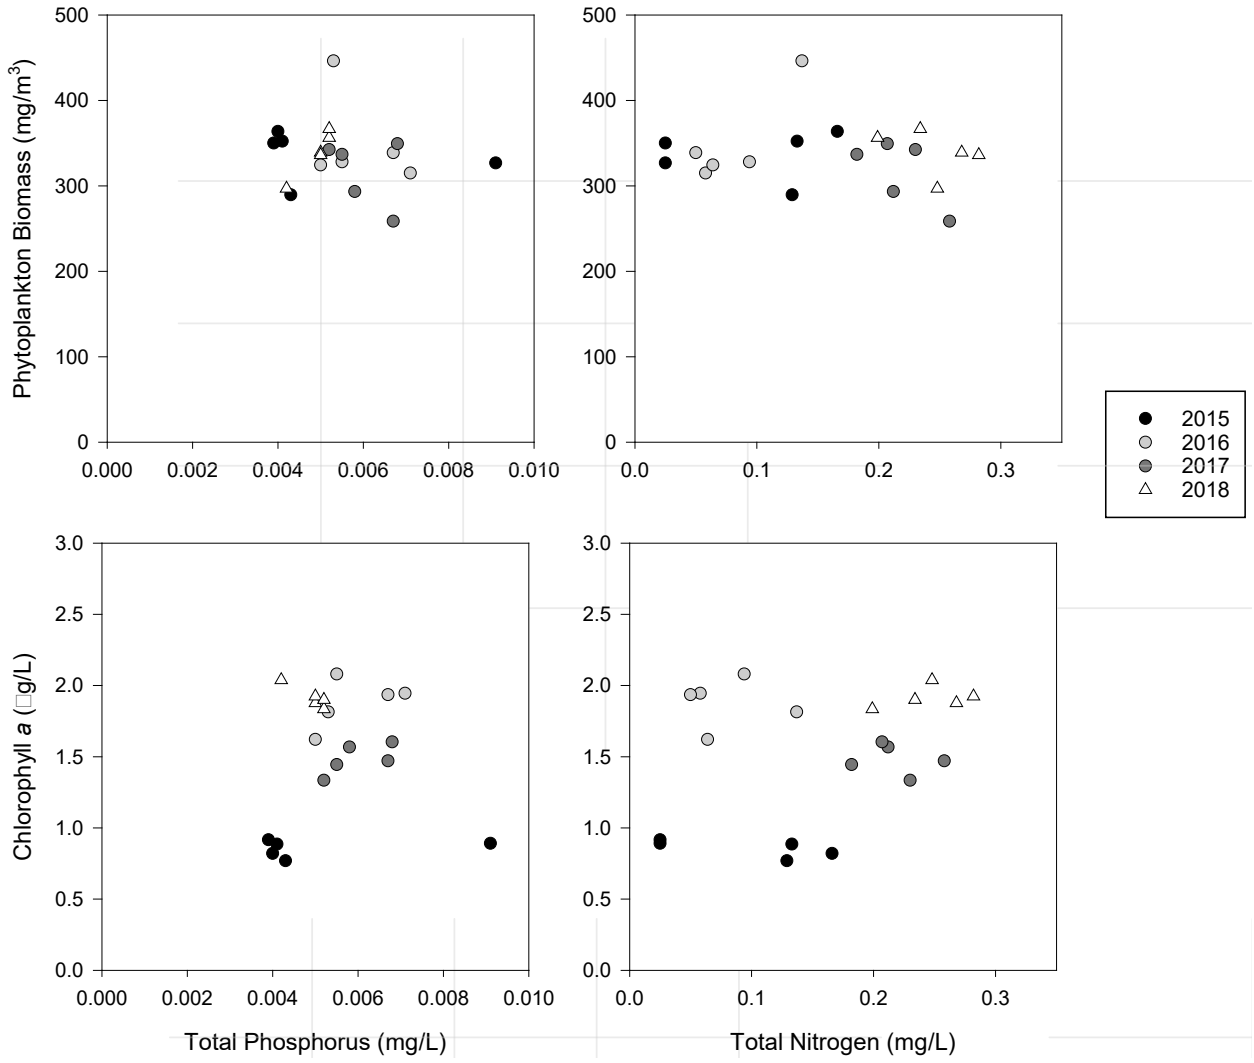
(a) Distributions of all variables violated the assumption of normality even after transformation; however, the results are considered reliable as the assumption of equal variances was not violated and ANOVA is robust against violations of the assumption of normality.

Note: *P*-values representing significant differences between areas (*P*<0.1) are **bolded**.



ANOVA= Analysis of Variance; Tukey's= Tukey's Honestly Significant Difference Test; *P*-value = probability value; <= less than; RA = Reference Area.

11.3.1.2 Evaluation of Variability in Phytoplankton Biomass and Chlorophyll a in the Near-field Area Relative to Nutrients

Scatter plots of nutrients, chlorophyll *a*, and phytoplankton biomass were prepared to assess variability of biomass and chlorophyll *a* in relation to variability in nutrient concentrations (i.e., TN and TP) in the Near-field area (Figure 11.3-4). Spatial variability in nutrient concentrations in the Near-field area during each sampling event was generally lower than the variability among years. Temporal variability in concentrations of TN was observed, but not for TP. There was no apparent relationship between nutrient concentrations and phytoplankton biomass or chlorophyll *a*, with the possible exception of TP versus chlorophyll a, where an outlier value for 2015 is inconsistent with a weak overall positive relationship.

The lack of apparent relationships in Figure 11.3-4 suggests that higher concentrations of total phosphorus and total nitrogen did not result in higher phytoplankton biomass or chlorophyll *a,* suggesting that nutrient inputs from treated sewage and Mine effluent in the Near-field area has not resulted in enhanced phytoplankton growth. However, other analyses have shown that chlorophyll *a* concentration and mean phytoplankton abundance and biomass were highest in the Near-field area compared to the Mid-field and reference areas during all years of monitoring, and Mid-field area results for each of these variables were also slightly elevated relative to the reference areas. In addition, TSI based on chlorophyll *a* concentration was highest in the Near-field area, followed by the Mid-field area, and lowest in the three reference areas. These results provide evidence of a gradient in primary productivity in Meliadine Lake, with the highest level in the Near-field area.

The apparent lack of relationships between nutrient concentrations and indicators of primary productivity do not necessarily indicate the lack of an effect on productivity. A relationship with TN is unlikely, because the limiting nutrient in Meliadine Lake is most likely phosphorus and possibly other micronutrients (e.g., silica). Detecting a relationship with TP may be difficult at this time, because the available sample size is small, TP results are near the DL where analytical variation is large, and there is limited variation in TP concentration to date. An increase in TP concentration of approximately 2 µg/L has resulted in a consistent, measurable effect on chlorophyll *a* concentration in parts of Lac de Gras as a result of the Diavik Diamond Mine effluent discharge, as shown by long-term monitoring by the Diavik AEMP (Golder 2017c). Continued monitoring of nutrients and productivity indicators, and periodic re-evaluation of nutrient-productivity relationships is recommended to better understand potential nutrient enrichment-related effects in Meliadine Lake.

Note: µg/L = micrograms per litre; mg/m^3 = milligrams per cubic metre; mg/L = milligrams per litre.

Figure 11.3-4: Nutrients versus Phytoplankton Biomass and Chlorophyll *a* Concentration in August in the Near-field Area, 2015 to 2018

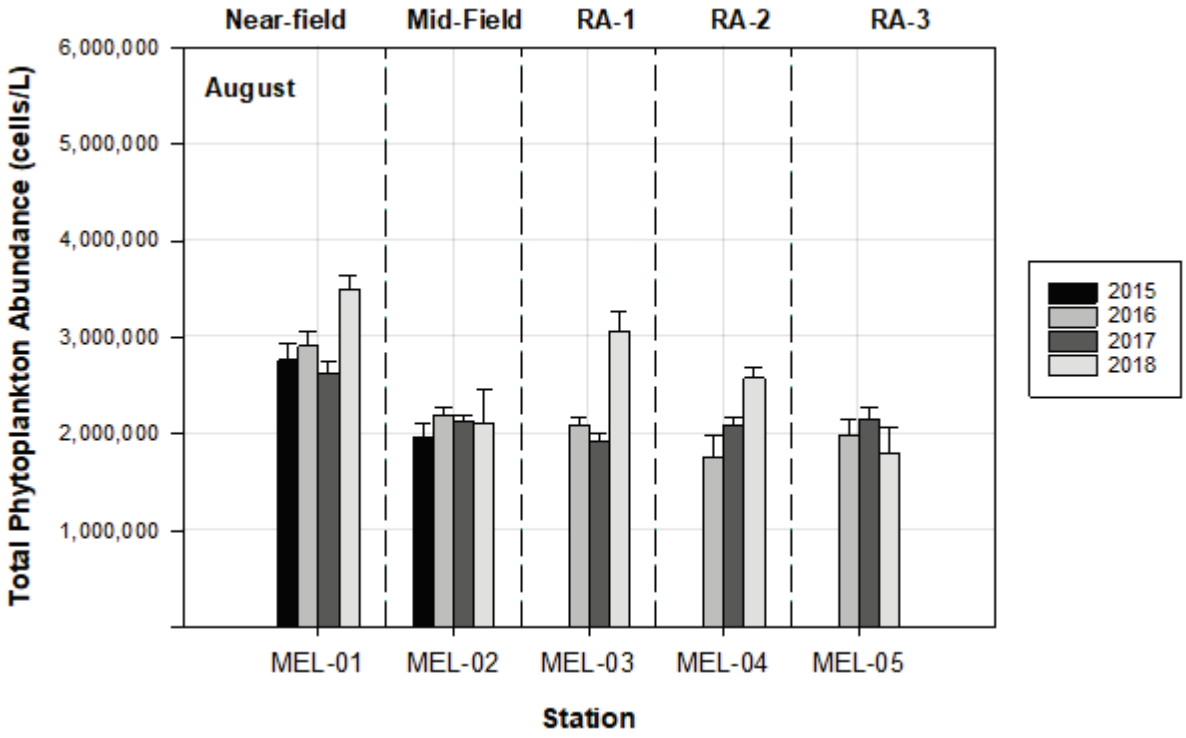
11.3.2 Trophic Status Classification

Concentrations of TP and chlorophyll *a*, and Secchi depth were measured as part of the water quality sampling program and were used to characterize the trophic status of Meliadine Lake. Summary tables for these variables and TSI are provided in Appendix 11C, Tables 11C-1 and 11C-2 for samples collected in August, in 2015 through 2018.

Chlorophyll *a* concentration was within the oligotrophic range throughout Meliadine Lake in 2015 through 2018 according to the general trophic classification systems of lakes (Table 7.1-2; Vollenweider 1968). Mean chlorophyll *a* concentration in 2018 ranged from 0.58 ± 0.03 μg/L in Reference Area 3 to 1.91 ± 0.03 μg/L in the Near-field area. Chlorophyll *a* concentration was within the same range in 2018 as in previous years of sampling (Appendix 11C, Table 11C-1. Table 11C-2).

Concentrations of total phosphorus were also consistent with an oligotrophic (nutrient-poor) classification based on the CCME (2004) trigger ranges (i.e., between 0.004 and 0.010 mg/L) (Table 7.1-3). The mean concentration of total phosphorus in 2018 ranged from 0.0039 ± 0.0007 mg-P/L in Reference Area 1 to 0.0073 ± 0.0015 mg-P/L in the Mid-field area, which is consistent with concentrations of total phosphorus measured in Meliadine Lake in previous years (Appendix 11C, Table 11C-1, Table 11C-2).

Secchi depth measurements throughout Meliadine Lake were also consistent with an oligotrophic classification (Appendix 11C, Table 11C-1, Table 11C-2). During the 2018 sampling program, mean Secchi depth in Meliadine Lake ranged from 6.4 m in the Near-field area to 7.0 m in Reference Area 3. Secchi depths measured in 2018 were consistent with Secchi depths measured in previous years.



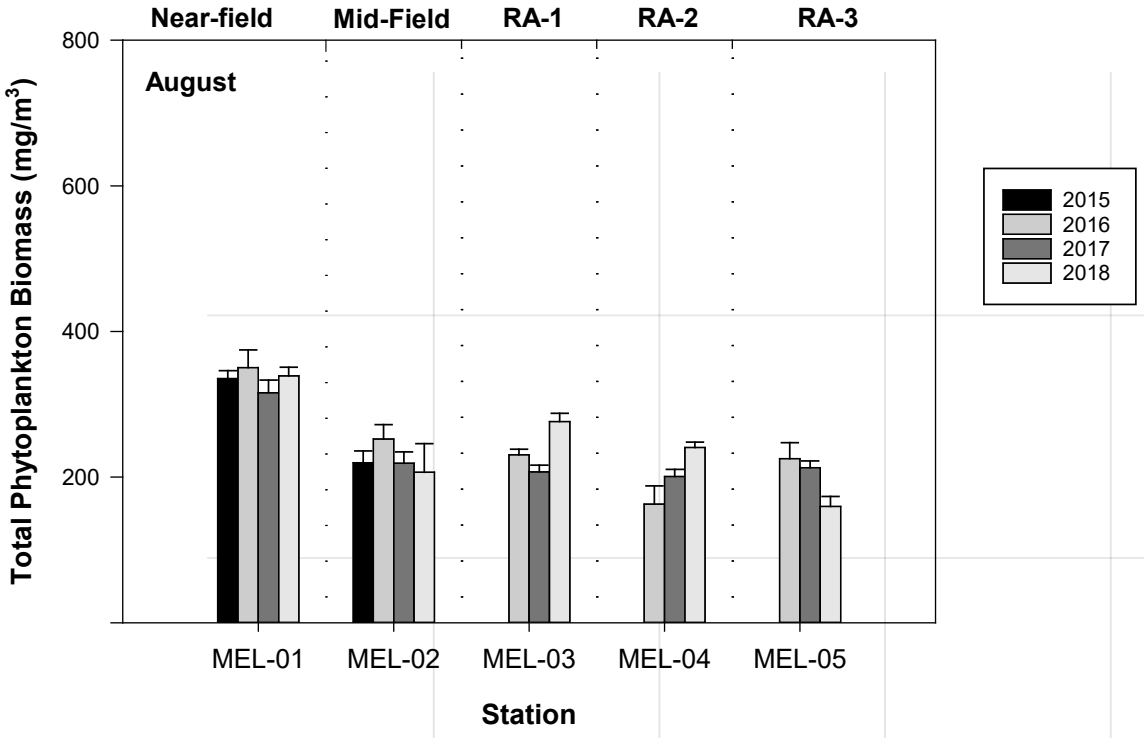
Based on the TSI calculations for chlorophyll *a* in August, the overall trophic status of Meliadine Lake was considered to be oligotrophic (Appendix 11C, Table 11C-2). TSI based on chlorophyll *a* concentration was highest in the Near-field area (37 ± 0.2), followed by the Mid-field area (29.3 ± 0.5), and lowest TSI was calculated at the three reference areas (ranging between 25.3 ± 0.5 and 25.7 ± 0.5). TSI values based on total phosphorus concentrations and Secchi depth were also low, and supported the oligotrophic classification based on the TSI for chlorophyll *a* in Meliadine Lake (Appendix 11C, Table 11C-2).

11.3.3 Phytoplankton

Descriptive statistics that summarize the phytoplankton abundance, biomass, and richness by season, year and area are provided in Appendix 11D, Table 11D-1. Relative abundance of major phytoplankton groups from samples collected in Meliadine Lake is provided in Appendix 11D, Table 11D-2. Raw phytoplankton taxonomic data for Meliadine Lake are provided in Appendix 11D, Tables 11D-3 to 11D-5.

11.3.3.1 Abundance

Phytoplankton abundance was higher in some exposure and reference areas in 2018 than in previous monitoring years but the spatial trend of abundance in 2018 was consistent with the trend observed during previous years (Figure 11.3-5). Mean phytoplankton abundance in the Near-field area in 2018 was 3,503,229 ± 137,000 cells/L, higher than the abundance observed in 2015 to 2017 which ranged between 2,637,110 ± 104,786 cells/L (2017) and 2,909,414 ± 154,628 cells/L (2016). Abundance in the Mid-field area was consistent with previous monitoring years and lower than in the Near-field area. Mean abundance was 2,101,478 ± 366,873 cells/L in the Mid-field area in 2018. Abundance in the reference areas was higher in 2018 than in 2016 or 2017 at Reference Areas 1 and 2, and slightly lower than abundance in previous years at Reference Area 3; mean phytoplankton abundance in the reference areas ranged between 1,803,459 ± 257,821 cells/L and 3,054,288 ± 212,971 cells/L in 2018. Abundance in each of the three reference areas was lower than in the Near-field area in 2018.

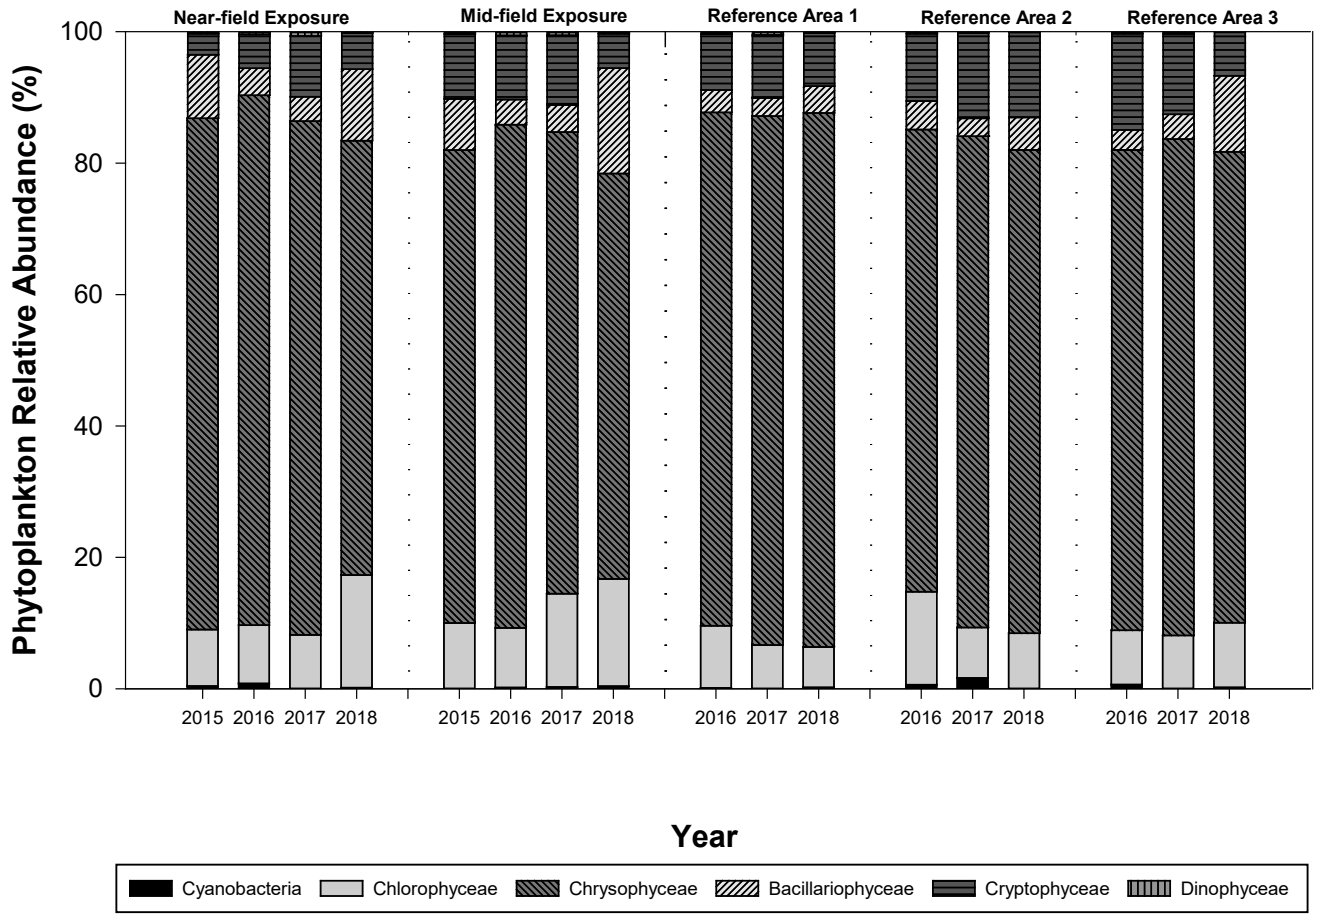


Notes: Mean values are presented for each area. Error bars represent standard error (SE). RA = Reference Area; cells/L = cells per litre.

Figure 11.3-5: Total Phytoplankton Abundance in Meliadine Lake in August, 2015 to 2018

11.3.3.2 Biomass

Phytoplankton biomass generally followed a similar spatial trend as abundance in 2018, while differences among years were less pronounced (Figure 11.3-6). In 2018, biomass was highest in the Near-field area, reaching 339.11 ± 11.93 mg/m^3 compared to 206.53 ± 39.33 mg/m^3 in the Mid-field area, and a range of 159.76 ± 13.52 mg/m^3 (MEL-05) to 276.08 ± 11.43 mg/m^3 (MEL-03) in the reference areas (Appendix 11D, Table 11D-1). Biomass in 2018 was generally consistent with previous years, with only slight increases observed in Reference areas 1 and 2, and a decrease in biomass observed in Reference Area 3 in 2018. The increase in phytoplankton abundance observed in the Near-field area in 2018 did not result in a corresponding increase in biomass, suggesting that the increase in abundance was likely a result of a larger number of smaller phytoplankton taxa in the Near-field area in 2018. Biomass in Reference Areas 1 and 2 was higher in 2018 than in 2016 and 2017, suggesting that the increase in abundance in these areas in 2018 can at least partially be attributed to a greater number of larger phytoplankton taxa.



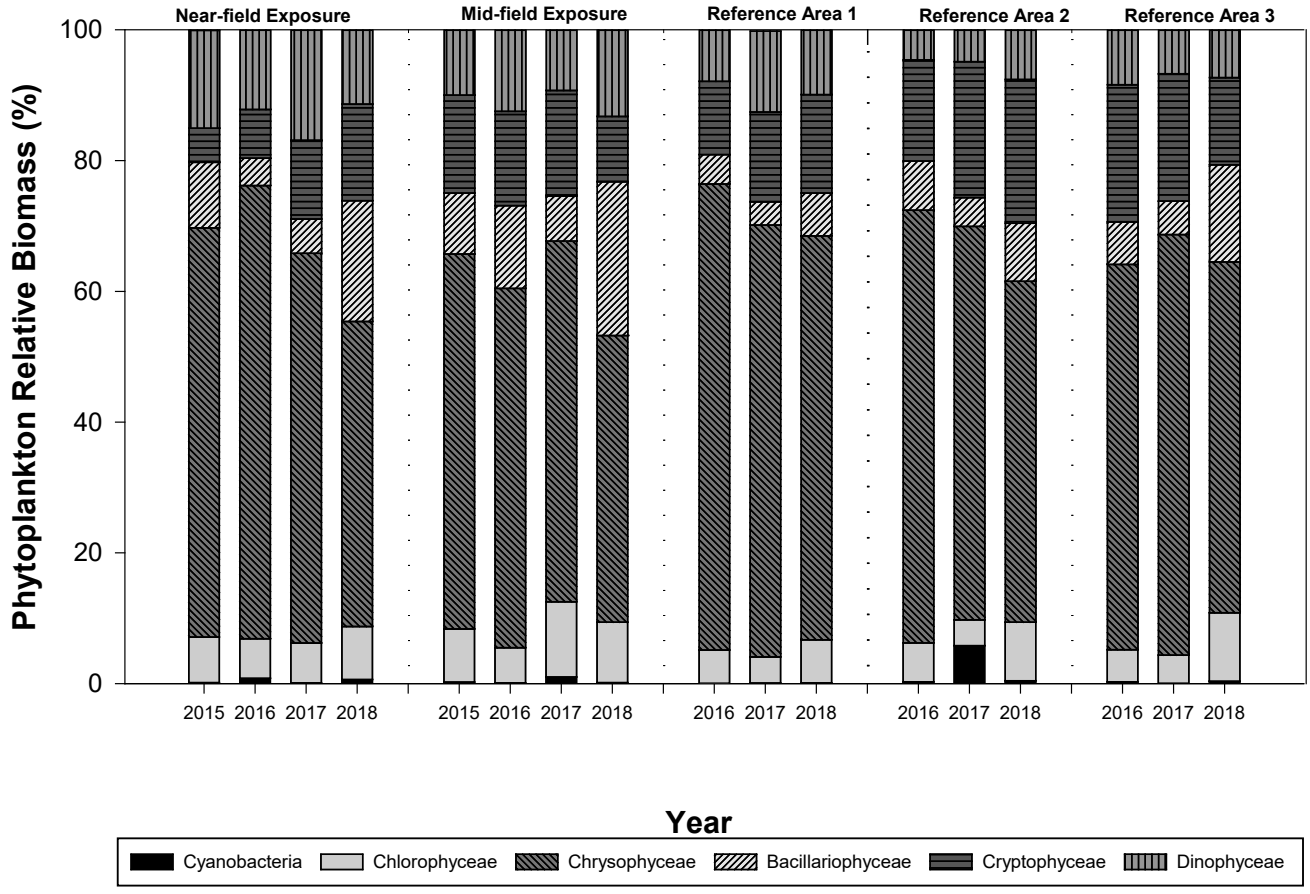
Notes: Mean values are presented for each area. Error bars represent standard error (SE). RA = Reference Area; mg/m^3 = milligrams per cubic metre.

Figure 11.3-6: Total Phytoplankton Biomass in Meliadine Lake in August, 2015 to 2018

11.3.3.3 Community Composition by Abundance

A total of 98 distinct phytoplankton taxa were identified in samples collected in Meliadine Lake in August 2015, 2016, 2017 and 2018. Overall, the relative abundance of major phytoplankton groups was similar throughout Meliadine Lake in 2018 to previous years. The most abundant, or dominant, taxa during each sampling program were golden algae of the group Chrysophyceae (Appendix 11D, Table 11D-2). Abundant taxa in the majority of samples collected included *Uroglena volvox*, *Chrysococcus sp.*, *Chrysochromulina* sp., and *Dinobryon* sp., all from the group Chrysophyceae (Appendix 7D, Tables 7D-3 and 7D-4). Chlorophytes (Chlorophyceae), diatoms (Bacillariophyceae) and cryptomonads (Cryptophyceae) were generally the next most abundant phytoplankton groups, with minor spatial and temporal variation in abundance observed for each group. Cyanobacteria and dinoflagellates (Dinophyceae) were largely absent from the phytoplankton community in Meliadine Lake, making up less than 1% the total relative abundance of phytoplankton in most samples.

The relative abundance of phytoplankton in August 2018 followed a similar spatial trend as in previous years with some minor changes in relative abundance in the exposure areas (Figure 11.3-7). Abundance was dominated by chrysophytes in all areas in 2018, which represented between 62% and 81% of total phytoplankton abundance (Appendix 11D, Table 11D-2). Diatoms contributed slightly more to overall abundance in the Near-field and Mid-field areas in 2018 (11% at MEL-01; 16% at MEL-02) than in previous years (4% to 10%). Chlorophytes also contributed more to overall abundance in 2018 in the exposure areas (17% at MEL-01; 16% at MEL-02) compared to previous years (4 to 14%). In general, higher variability in the relative abundance of chlorophytes, diatoms and dinophytes was observed in the exposure areas, higher relative abundance of chrysophytes was observed in the reference areas, and low relative abundance of cyanophytes was observed in all areas.

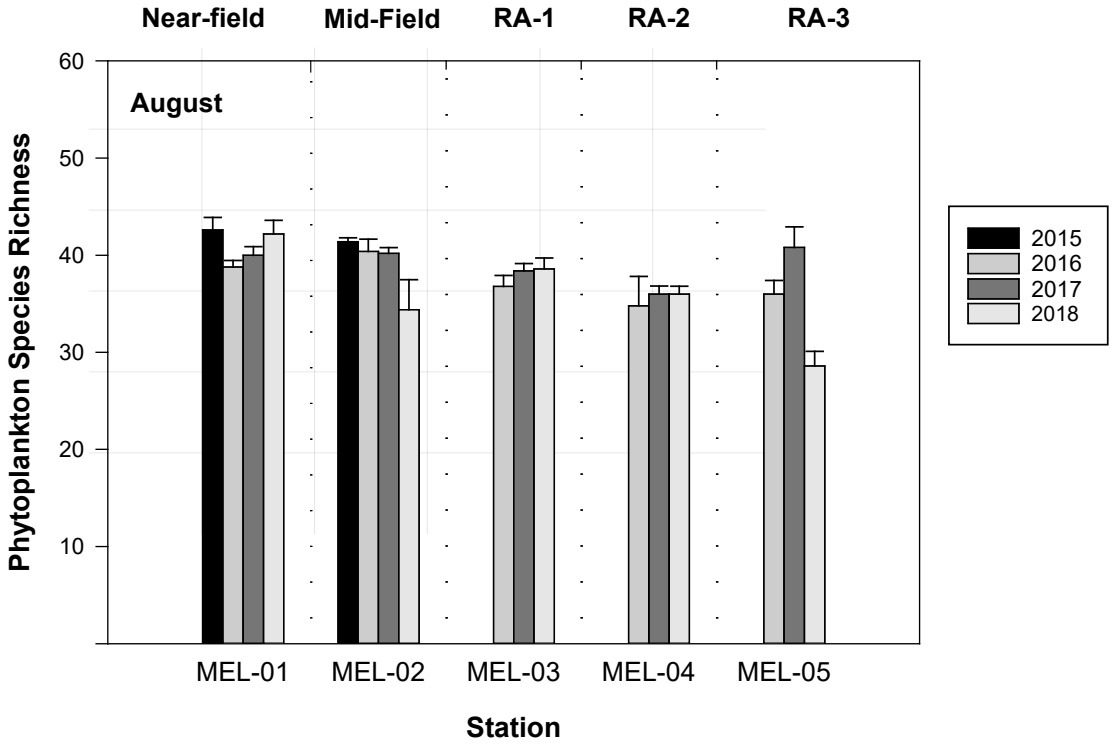


Note: Bars represent mean values for each area.

Figure 11.3-7: Relative Abundance of Major Phytoplankton Groups in Meliadine Lake, 2015 to 2018

11.3.3.4 Community Composition by Biomass

The relative biomass of major phytoplankton groups in Meliadine Lake followed a similar trend as relative abundance, with the only notable differences between 2018 and previous years observed in the exposure areas (Figure 11.3-8). As with abundance, chrysophytes contributed the most to relative biomass in all areas in Meliadine Lake; however, the relative abundance of chrysophytes was lower in the exposure areas (47% at MEL-01; 44% at MEL-02) than in the reference areas (52% to 62%) (Appendix 11D, Table 11D-2). The relative biomass of diatoms was higher in the exposure areas in 2018 (19% to 24%) than in the exposure areas in previous years (4% to 13%) or in the reference areas in all years (4 to 15%). The relative proportions of chlorophytes, cryptomonads and dinoflagellates by biomass showed no discernable trends between exposure and reference areas or among years. Dinoflagellates generally contributed more to relative biomass compared to relative abundance (i.e., larger cells but rare), while the relative biomass of other major groups was generally proportional to their relative abundance (i.e., smaller cells but common).



Notes: Bars represent mean values for each area (n=5).

Figure 11.3-8: Relative Biomass of Major Phytoplankton Groups in Meliadine Lake, 2015 to 2018

11.3.3.5 Species Richness

Species richness was relatively consistent throughout much of Meliadine Lake with few observable trends among years or stations (Figure 11.3-9). Richness varied little between the exposure areas and the reference areas in 2018 and among years in any area. In 2018, mean richness was highest in the Near-field area (42 ± 1 taxa) and lowest in Reference Area 3 (29 ± 2 taxa) (Appendix 11D, Table 11D-1). Richness in the Near-field area in 2018 was consistent with richness observed in previous years. Richness in the Mid-field area was lower in 2018 (34 ± 2 taxa) than in previous years, when mean richness ranged between 40 and 41 taxa. Species richness in Reference Area 3 was notably lower than in all other areas (29 ± 2 taxa) and in general was highly variable among years in this area.

Notes: Mean values are presented for each area. Error bars represent standard error (SE). RA=Reference Area.

Figure 11.3-9: Total Phytoplankton Species Richness in Meliadine Lake, 2015 to 2018

11.3.3.6 Statistical Comparisons of Phytoplankton Community Variables

Statistical comparisons of phytoplankton community variables from samples collected in August 2016, 2017 and 2018 were made to evaluate spatial variability among the five areas of Meliadine Lake. Data collected in August 2015 was omitted from statistical comparisons among areas in Meliadine Lake due to a lack of sampling in the reference areas. A summary of statistical comparisons of variables among Near-field and Mid-field areas and the three reference areas in August 2016, 2017 and 2018 is presented in Table 11.3-2.

Differences observed in the abundance, biomass, and richness of the phytoplankton community in August 2016 and August 2017 in Meliadine Lake are summarized below:

- Phytoplankton abundance was significantly different among the five sampling areas in 2016 (P <0.001), 2017 (P = 0.004) and 2018 (P <0.001) (Table 11.3-2). Pairwise comparisons showed that abundance in the Near-field area was significantly higher than in the Mid-field area and each of the three reference areas in 2016 and 2017. In 2018, the Near-field area was significantly different than the Mid-field area and two of the three reference areas, while significant differences were also observed between the Mid-field area and one of the reference areas (Reference Area 1) and among some of the reference areas. There was no significant difference in abundance between the Mid-field exposure area and the reference areas or among the reference areas in 2016 or 2017.
- Phytoplankton biomass was also significantly different (P <0.001) among sampling areas in all years (Table 11.3-2). Pairwise comparisons of biomass estimates showed a similar trend as abundance in all years with significant differences between the Near-field area and all other areas in each year. A significant difference was also observed between the Mid-field area and Reference Area 2 in 2016 (P = 0.068) and between each of the reference areas in 2018.
- Phytoplankton species richness was significantly different among areas overall in 2016 (P = 0.081), 2017 (P = 0.065) and 2018 (P = 0.006); however, comparatively fewer significant differences were observed in pairwise comparisons of exposure and reference areas in 2016 and 2017 (Table 11.3-2). In 2016, no significant differences were observed in pairwise comparisons between areas, while in 2017 the only significant difference observed was between the Mid-field area and Reference Area 2. In 2018, significant differences were observed between the Near-field area and the Mid-field area and reference areas, among the three reference areas, and between the Mid-field area and Reference Area 3.

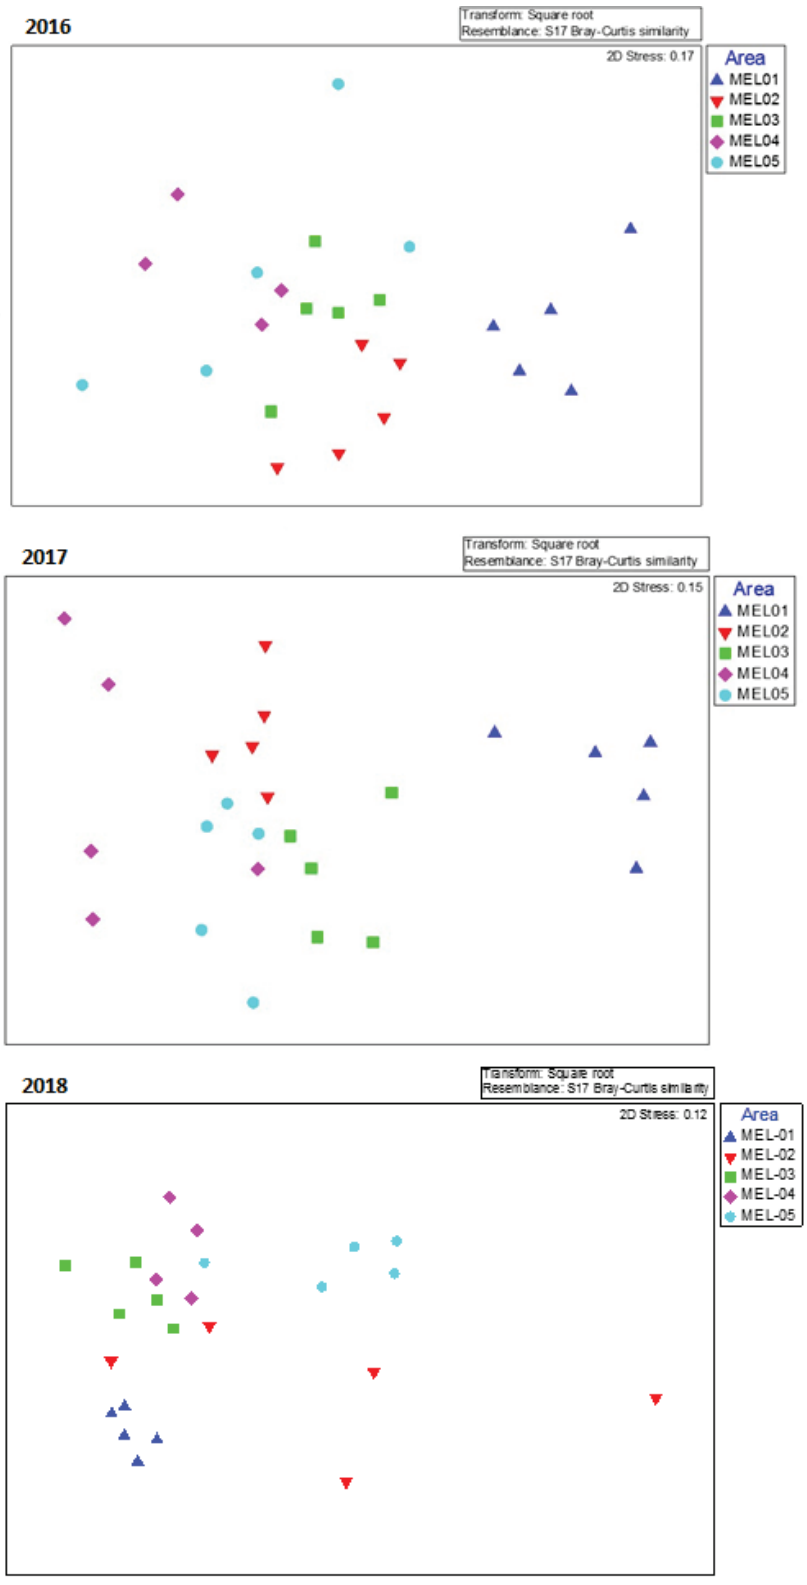
11.3.3.7 Multivariate Analysis



Two nMDS dimensions were derived from the phytoplankton biomass data collected in Meliadine Lake. Phytoplankton biomass in August 2016, 2017 and 2018 were analyzed separately to enable a good fit of the ordination results. The nMDS ordination of the samples by area illustrates the degree of similarity in community composition among stations in each area.

The stress value of the final configuration was 0.17 for August 2016, 0.15 for August 2017, and 0.12 for August 2018, which represent a “fair” fit (<0.2) of the ordination results to the input data in qualitative terms (Clarke 1993). According to the categories provided by Clarke (1993), some interference may be present, which could confound the interpretations made from the plots, so results should be interpreted with caution. One sample from August 2016 (MEL-04-03) was excluded from the analysis due to major differences in phytoplankton community compared to other locations.

The majority of stations in 2016 clustered together by area with more similarities present among the reference areas than among the exposure areas (Figure 11.3-10). Differences in taxonomic composition by biomass were especially apparent between the Near-field area (MEL-01) and all other areas in August 2016. The Mid-field area (MEL-02) more closely resembled the reference areas, and stations clustered relatively close together. Some variability in taxonomic composition was apparent in the reference areas, especially in Reference Area 3 (MEL-05), for which individual stations were not closely related.

In August 2017, most stations were also clustered together by area (Figure 11.3-10). Stations in the Near-field area (MEL-01) were again clustered separately from the Mid-field (MEL-02) and reference areas, indicating taxonomic composition by biomass was different in the Near-field area in 2017. Some variability in community composition was also evident in Reference Area 2 (MEL-04) in August 2017, when the majority of stations did not cluster together with the other reference areas.

In August 2018, generally similar results were observed as in 2016 and 2017, with stations in the Near-field area (MEL-01) clustering closely together despite the change in sampling locations in this area in 2018. In the Mid-field area (MEL-02) in 2018, notably higher variability between stations was observed in 2018 than in previous years, with three Mid-field stations clustering relatively far away from all other stations. The results suggest high variability in community composition in the Mid-field area was present in 2018. The observed differences can be partially explained by changes made to the sampling design in 2018, as two of the Mid-field stations which clustered away from the Near-field and reference stations were the stations which were added in 2018 (MEL-02-06 and MEL-02-08); however, the station clustering farthest from the other locations was MEL-02-02, which was sampled in 2016 and 2017, suggesting that a relatively large amount of natural variability may exist in the Mid-field area. As in previous years, all three reference areas clustered relatively close together in 2018.

Notes: MEL-04-03 in 2016 was excluded from analysis due to major differences in phytoplankton community relative to all other stations.

Figure 11.3-10: Ordination Plot of August Phytoplankton Biomass in Meliadine Lake in 2016 to 2018

11.3.3.8 Comparisons to Normal Ranges

Normal ranges for phytoplankton abundance, biomass, and richness along with concentrations of chlorophyll *a* were calculated using Mid-field area and reference area data collected during the 2015 to 2018 sampling programs. Data collected from Near-field area in all years was excluded from the normal range calculation due to suspected influences on phytoplankton monitoring variables from effluent inputs during these years. A comparison of mean and median values from 2018 was then compared against the normal ranges calculated for each parameter.

Mean and median values for some parameters in 2018 exceeded the upper bounds of the normal ranges (Table 11.3-3). Mean phytoplankton abundance and median phytoplankton biomass and chlorophyll *a* concentration in the Near-field area were higher than their respective normal range upper bounds in 2018. Mean species richness in 2018 fell within the normal range in the Near-field and Mid-field areas and the reference areas. Mean abundance, median biomass and median chlorophyll *a* concentration in the Mid-field area and the reference areas were within the normal range for each parameter.

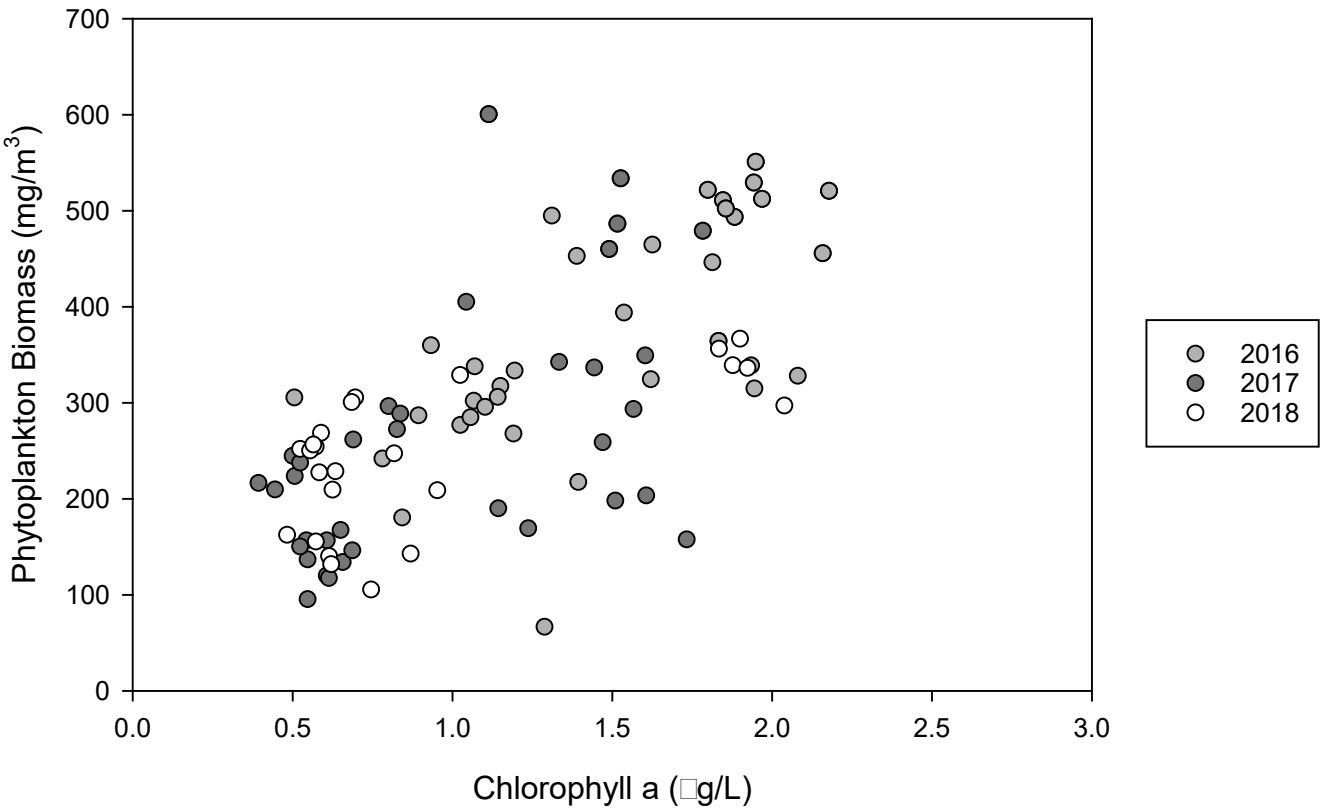
Table 11.3-3: Normal Ranges for Selected Phytoplankton Parameters in Meliadine Lake, 2018

Parameter	Unit	n	Calculation Method[c]	Normal Range		Mean/Median[a]		
				Lower Bound	Upper Bound	Near-field	Mid-field	Reference Area[b]
Phytoplankton Abundance	cells/L	69	PI(λ)	1,510,476	3,045,764	**3,503,229**	2,101,478	2,479,844
Phytoplankton Biomass	mg/m^3	69	Percentile	161	305	**339**	209	221
Species Richness	No. of taxa	69	PI(λ)	32	43	42	34	34
Chlorophyll *a*	µg/L	139	Percentile	0.52	1.18	**1.94**	0.84	0.60

(a) Lake area means were calculated using the back-transformed mean when the normal range was defined as the prediction interval using Box-Cox transformed data. The median was used when the calculation method was Percentile.

(b) Reference area data were pooled from Reference Areas 1, 2, and 3.

(c) Percentile mean calculated from 30 iterations of Normal Range calculations



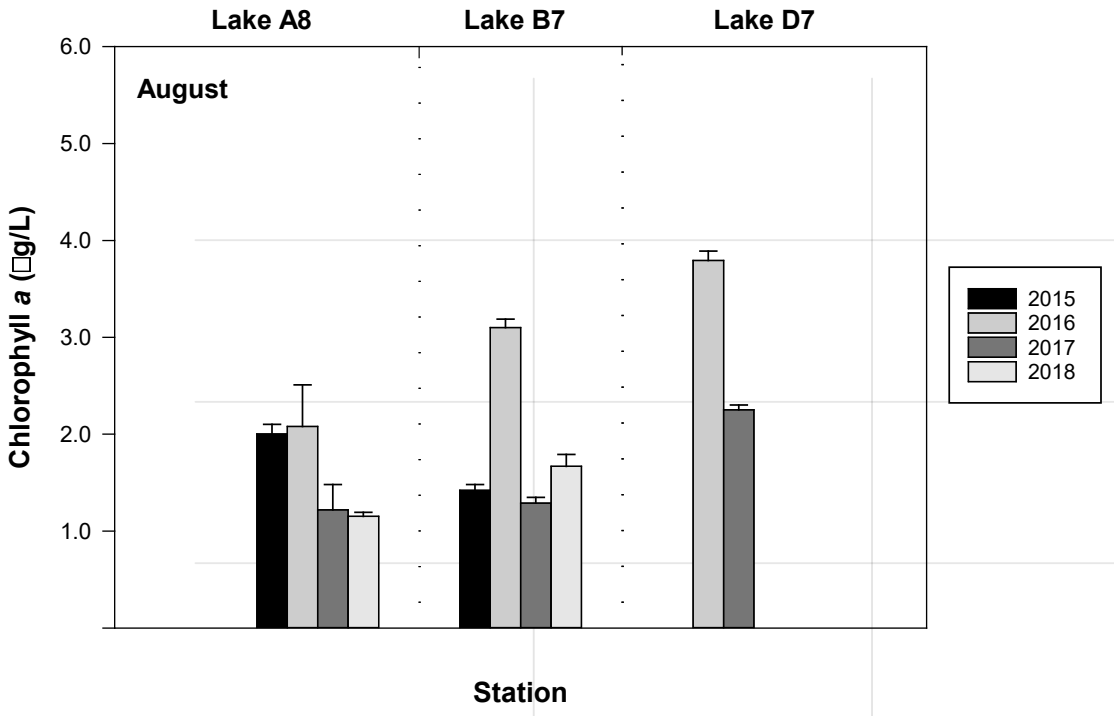
Bolded concentrations exceed the upper bound of the normal range.

Percentile = 2.5th and 97.5th percentiles; PI(λ) = 80% prediction interval on Box-Cox transformed data.

cells/L = cells per litre; mg/m^3 = milligrams per cubic metre; µg/L = micrograms per litre.

11.3.3.9 Relationship Between Phytoplankton Biomass and Chlorophyll a

The correlation between chlorophyll *a* concentration and total phytoplankton biomass calculated from phytoplankton taxonomy samples was examined to evaluate whether chlorophyll *a* can be used as an indicator of phytoplankton biomass. In order to provide the most robust dataset for the analysis with the largest range of potential biomass values, chlorophyll *a* and biomass data from July, August and September in 2016 and July and August in 2017 were included, along with data from August 2018. Data collected in 2015 and September 2017 were excluded from the regression analysis due to reliability concerns (Golder 2018c). Based on data from all years combined, there was a highly significant but weak to moderately strong linear relationship (*P*-value = <0.0001; R^2 = 0.50) between phytoplankton biomass and chlorophyll *a* concentration (Figure 7.3-16). Much of the unexplained variation between the two variables is likely explained by a disproportionate effect by certain phytoplankton groups on the proportion of chlorophyll *a* in phytoplankton wet weight (Kasprzak et al. 2008; Felip and Catalan 2000). For example, dinoflagellates generally have a disproportionately lower amount of chlorophyll *a* for their size when compared with phytoplankton of the groups Chlorophyta and cyanobacteria. Overall, a generally linear trend is apparent, which suggests that chlorophyll *a* is a suitable surrogate for taxonomic estimates of phytoplankton biomass in the future. Additional data points from future monitoring years will help to define the relationship between chlorophyll *a* and phytoplankton biomass in Meliadine Lake.



Note: Chlorophyll *a* and biomass data from September 2017 were excluded due to different filters used for field collection.
mg/m^3 = milligrams per cubic metre; µg/L = micrograms per litre.

Figure 11.3-11: Chlorophyll a vs. Phytoplankton Biomass in Meliadine Lake, 2015 to 2018

11.4 Peninsula Lakes

11.4.1 Chlorophyll *a*

Chlorophyll *a* concentrations in the peninsula in lakes A8 and B7 in 2018 were generally similar to concentrations observed in 2017. Overall, chlorophyll *a* concentrations varied by up to two-fold among years and were generally higher in Lake D7 compared to the other two lakes (Figure 11.4-1). Mean chlorophyll *a* concentration in Lake A8 was 1.2 ± 0.04 µg/L in 2018 compared to a mean of 1.2 ± 2.4 µg/L in 2017, 2.1 ± 0.4 µg/L in 2016, and 2.0 ± 0.1 µg/L in 2015. Mean chlorophyll *a* concentration in Lake B7 was 1.7 ± 0.1 µg/L in 2018 compared to a mean of 1.3 ± 0.06 µg/L in 2017, 3.1 ± 0.09 µg/L in 2016, and 1.4 ± 0.06 µg/L in 2015. Samples for chlorophyll *a* analysis were not collected from Lake D7 in 2015 or 2018.

Notes: Mean values are presented for each area. Error bars represent standard error (SE). µg/L = micrograms per litre.

Figure 11.4-1: Mean Chlorophyll *a* Concentrations in the Peninsula Lakes, 2015 to 2018

11.5 Summary

A summary of the key findings from the plankton study is provided below:

- Nutrient concentrations during plankton sampling events in Meliadine Lake were generally low, with variability observed among years and spatial variability observed in TN concentrations in August 2017 and 2018; no clear spatial trend was observed in TP concentration in any year. TN in August 2017 and 2018 was significantly higher in the Near-field area than in the reference areas; however, TP concentrations were not significantly different among areas.
- Chlorophyll *a* exhibited high annual variability and followed a clear spatial trend in 2018 with higher concentrations in the Near-field area than in the Mid-field area and the reference areas. Concentrations of chlorophyll *a* in 2018 were consistent with the highest concentrations observed during the pre-construction phase of the Mine (August 2016).
- Trophic status calculations indicated conditions were oligotrophic in all areas and years. TSI based on chlorophyll *a* concentration was highest in the Near-field area, followed by the Mid-field area, and lowest in the three reference areas.
- Higher phytoplankton abundance and biomass were observed in the Near-field area compared to other areas. Abundance, but not biomass, was higher in the Near-field area in 2018 than in previous years. Spatial trends were consistent with previous years; however, higher variability was observed among years in the reference areas with the inclusion of the 2018 data, which interfered with the evaluation of spatial trends in the phytoplankton community.
- Phytoplankton communities in Meliadine Lake were generally dominated by the Chrysophyceae (golden algae). Limited spatial variability was observed in relative abundance and biomass of major taxonomic groups. However, multivariate analysis indicated differences among areas in community composition at the species level.
- Chlorophyll *a* concentrations had a significant, weak to moderately strong linear relationship with phytoplankton biomass. Given this relationship, the current results suggest chlorophyll *a* is a potentially useful indicator of phytoplankton biomass in Meliadine Lake. The addition of data collected during future studies may help to further refine the relationship.
- Normal ranges were developed for the phytoplankton community using a combination of data obtained in 2015, 2016, 2017 and 2018. Phytoplankton abundance, phytoplankton biomass, and chloroplhyll *a* concentrations in the Near-field area were above the upper bound of the normal range in Meliadine Lake.
- Higher chlorophyll *a* concentration and phytoplankton biomass, and unique phytoplankton community structure (based on multivariate analysis) in the Near-field area indicate potential nutrient enrichment originating from the treated Mine effluent. Biomass and chlorophyll *a* in the Near-field area in 2018 were within the range of results observed during the pre-construction phase of the Mine suggesting that potential nutrient enrichment may have began prior to initiation of the construction phase of the Mine (i.e., from the exploration camp STP discharge).
- Based on the August phytoplankton dataset collected from Meliadine Lake since 2015, late-summer phytoplankton monitoring is considered a useful monitoring tool for Meliadine Lake to detect potential effects resulting from nutrient enrichment.

11.6 Recommendations

The findings of the phytoplankton targeted study suggest that monitoring phytoplankton abundance and biomass as well as chlorophyll *a* could be a useful addition to the AEMP, at least for one additional year in August during operational discharge. This component would assist in assessing nutrient enrichment effects under new discharge conditions (i.e., operational instead of construction). The relationship between phytoplankton biomass and chlorophyll *a* would also be strengthened with another year of monitoring.

12.0 OVERALL SUMMARY AND CONCLUSIONS

12.1 EEM

The revised objective of the Cycle 1 EEM study was to assess the effect of the treated mine effluent discharge from MEL-14 on BIC and fish population health in Meliadine Lake. This objective was achieved by evaluating effluent chemistry and toxicity, and by testing if statistical differences in indicators of fish health (e.g., energy storage, energy usage, and survival) and BIC (e.g., density, family-level taxonomic richness, evenness index, and BCI) between exposure and reference areas were present, and greater than CESs. In addition, the manner in which effluent mixes in the receiving environment was studied.

Effluent chemistry met MDMER effluent limits and effluent was not acutely toxic to Rainbow Trout or *Daphnia magna*. Sublethal toxicity was observed on *Lemna minor* growth and *Ceriodaphnia dubia* reproduction, but not on Fathead Minnow survival and growth or *Pseudokirchneriella subcapitata* growth. Further study would be required to extrapolate laboratory results to potential field effects. The results of the effluent plume delineation study indicated that the effluent mixes relatively quickly within the mixing zone, with the maximum effluent concentration observed at 100 m away from the diffuser as less than 2%, and at 250 m as 1%.

Concentrations of several nutrients and metals (i.e., nitrate, nitrate and nitrite, total aluminum, arsenic, lithium, magnesium, and titanium as well as dissolved aluminum, arsenic, cobalt and lithium) in lake water were two times higher in the Near-field area compared to the Reference Area 1. However, concentrations of all water quality parameters with available guidelines were below the CWQG-PAL.

Sediment quality was variable between the exposure and reference areas, which was also observed in 2015 and 2016. Sediments at Near-field area stations were mostly silt-dominated in comparison to sediments sampled at Reference Area 1, which had a higher percentage of sand. Several metals had concentrations that were more than two times higher in the Near-field area than in Reference Area 1. ISQG exceedances for arsenic, cadmium and chromium were identified in both exposure and reference areas. Near-field arsenic concentrations in sediments were also above the PEL, by less than a factor of 2. The arsenic concentration at one reference station was above the PEL, by a factor of 1.4. All other sediment metal concentrations reported in 2018 were below sediment quality guidelines. For metals above sediment quality guidelines in the Near-field area, concentrations in 2018 were lower than those reported under baseline conditions in 2015 and 2016. Higher concentrations of metals and finer sediments in the Near-Field area compared to reference areas was also observed under baseline conditions prior to the Mine effluent discharge; therefore, Near-field area concentrations are considered representative of pre-discharge conditions, and not indicative of a Mine-related effect.

Meliadine Lake benthic invertebrate communities were reflective of typical subarctic communities and were characterized by low densities and low to moderate family level richness. Communities were dominated by the midge family Chironomidae, with fingernail clams (Pisidiidae) subdominant. Snails (Gastropoda) were observed in the Near-field area at higher proportions than in other areas, and amphipods were only present outside of the Near-field area, which likely reflects differences in habitat between the Near-field area and other sampling areas, as a result of taxon-specific habitat preferences. No statistically significant differences in benthic effect and supporting endpoints were detected between Near-field area and Reference Area 1. Total density values were lower in the Near-field area compared to Reference Area 1, but both areas had similar family level richness. Comparisons between the Near-field area and Reference Area 1 showed higher diversity, evenness, and dissimilarity from the reference area median community in the Near-field area. The observed differences in these endpoints likely reflect differences in habitat, particularly differences in sediment composition, that were predent in the sampling areas prior to Mine discharge from MEL-14.

Threespine Stickleback was the only species captured in sufficient abundance from Meliadine Lake to support sample size requirements of the EEM fish population survey. A statistically significant difference between fish captured in the Near-field area and Reference Area 1 was observed for female condition; however, the effect size of 6% was less than the CES of 10%. A similar response was not observed in supporting energy storage endpoints (i.e., relative liver weight and relative egg weight). Statistical analyses were confounded by a lack of a predictive relationship between age and body weight, and Threespine Stickleback being at a variety of reproductive stages at the time of sampling. These factors contributed to low statistical power for some endpoints. Threespine Stickleback were also commonly parasitized by tapeworms, which increased variability in the dataset; however, when infected fish were included in the statistical analysis, increased variability was offset by increased sample sizes resulting in a net increase in statistical power.

In conclusion, there was no evidence of Mine-related effects on the BIC or Threespine Stickleback in the exposure area of Meliadine Lake. Future EEM study designs should continue to consider the influence of habitat variation on benthic invertebrate communities and of high incidence of parasitism on Threespine Stickleback.

12.2 AEMP

12.2.1 Updated Low Action Levels and Response Framework

The AEMP Response Framework links monitoring results to management actions, with the purpose of maintaining the assessment endpoints within acceptable ranges. It is a systematic approach for evaluating AEMP results and responding appropriately, such that potential unexpected effects are identified, and mitigation is undertaken to reduce or reverse them, thereby preventing the occurrence of a significant adverse effect (WLWB 2010). This is accomplished by continually evaluating monitoring data and implementing follow-up actions (e.g., confirmation, further study, mitigation) at pre-defined levels of change in measurement endpoints (i.e., Action Levels).

The low Action Levels are designed to provide an early-warning indication of potential adverse effects to plankton and benthos (i.e., food for fish), fish health, and maintenance of ecological function (including water and sediment quality). They are designed so that changes of sufficient magnitude to trigger a low Action Level are reported, documented, investigated, and ultimately addressed (i.e., mitigation measures or changes to the Mine operation are implemented) before Significance Thresholds would ever be reached. If a low Action Level is reached, then Medium and High Action Levels would be developed to further support adaptive management.

In response to comments made on the 2017 AEMP Annual Report, the Mine committed to updating the low Action Levels for Water Quality in anticipation of comparing the 2018 data to these Action Levels. These updates are described below.

12.2.1.1 Toxicological Impairment – End of Pipe Toxicity

The revised low Action Level for end of pipe toxicity is:

- A persistent sublethal toxic effect is observed on test organisms in end-of-pipe samples.

Persistent is defined as sublethal toxicity observed in the same test organisms in three consecutive end-of-pipe samples. A sublethal toxic effect is defined as an IC25 less than the highest test concentration.

If this low Action Level was reached, then additional investigation may include evaluating the potential extent of sublethal effects in the receiving environment, toxicity identification evaluation and/or toxicity testing at the edge of the mixing zone.

12.2.1.2 Toxicological Impairment – Aquatic Life

Toxicological impairment of aquatic life in the receiving environment will be evaluated using a combination of comparisons of concentrations between the Near-field and reference areas, comparisons to AEMP benchmarks and the normal range, and evaluation of differences temporal trends between reference and exposure areas.

The list of water quality parameters to be assessed for this type of effect is focused on parameters that can affect the suitability of water to support an aquatic ecosystem, namely those parameters that can exert toxicity. These parameters include pH, dissolved oxygen, TSS, TDS (calculated), chloride, fluoride, sulphate, total ammonia, nitrate, nitrite, and metals. A number of parameters were excluded from this list for the following reasons:

- Specific conductivity (field-measured and laboratory-measured) was excluded, because (1) it is not a measure of the concentration of substances in water, and (2) TDS is a more relevant parameter for evaluating effects related to increased dissolved ion concentrations, with extensive toxicological literature to support the assessment.
- Major ions other than those that have water quality guidelines for the protection of aquatic life (i.e., chloride, fluoride, nitrate, nitrite) were excluded, because these parameters are either included in the determination of TDS or are evaluated separately; however, if TDS triggers the low Action Level, then individual ions will be evaluated further.
- Carbonate was excluded because they are not detectable at the pH range encountered in Meliadine Lake.
- Hardness, which is integrated into the calculation of AEMP benchmarks for certain parameters (e.g., copper, lead, nickel), was excluded because it is not a parameter of toxicological concern.
- Total alkalinity and bicarbonate (which is redundant with total alkalinity) were excluded because they are not parameters of toxicological concern
- Nitrate + nitrite were excluded because these ions are evaluated separately as nitrate and nitrite.
- Nutrients that are generally not toxic to aquatic organisms (i.e., phosphorus and some forms of nitrogen) were excluded, but are evaluated under the Nutrient Enrichment hypothesis, with corresponding Action Levels.
- Most dissolved metals were excluded, because water quality guidelines for metals are typically evaluated in terms of the total concentrations, and evaluating total metals is the more conservative approach; dissolved zinc is the exception, because the new CWQG-PAL is for dissolved zinc.
- total cyanide and WAD cyanide, because the biologically important form of cyanide is free cyanide.

The water quality Low Action Level for evaluating toxicological impairment has three conditions:

- concentration in Near-field area is significantly greater compared to the reference areas, and greater than the normal range
- concentration in Near-field area exceeds 75% of the AEMP benchmark
- a divergence of trends in concentration is observed between the Near-field and reference areas

Each condition must be met for the low Action Level to be triggered.

For parameters without an AEMP benchmark, the second criterion is not applicable; for these parameters, the low Action Level trigger is evaluated based on criteria 1 and 3. In the event that a low Action Level trigger is determined for a parameter with no AEMP benchmark, one of the anticipated response actions will be to develop

a benchmark. However, because parameters with no available water quality guidelines or benchmarks are typically not of toxicological concern, a Low Action Level would only be triggered (and an AEMP benchmark developed as a follow-up action) if (1) the Near-field area concentration was greater than five times the analytical detection limit, and (2) the magnitude of difference relative to the reference area was greater than two-fold. Once the benchmark is developed, the low Action Level can be reassessed for these parameters based on all three criteria.

AEMP benchmarks were selected from site-specific surface water quality objectives (SSWQO) developed specifically for the Mine, federal water quality guidelines for the protection of aquatic life (i.e., CWQG-PAL and Federal Environmental Quality Guidelines [FEQG]), and benchmarks developed by other northern mines for tundra lakes (Table 12.2-1).

Table 12.2-1: AEMP Benchmarks for Evaluating the Potential for Toxicological Impairment of Aquatic Life

Parameter	Unit	SSWQO	CWQG-PAL	FEQG	Other Source	Selected AEMP Benchmark	Source
pH	-	-	6.5 - 9.0	-	-	6.5 to 9.0	CWQG-PAL
Dissolved oxygen	mg/L	-	6.5	-	-	6.5	CWQG-PAL
Total dissolved solids	mg/L	-	-	-	500	500	Alaska DEC 2012
Chloride	mg/L	-	120	-	-	120	CWQG-PAL
Sulphate	mg/L	-	-	-	123[(k)]	123[(k)]	BC ENV 2018
Cyanide (free)	mg/L	-	0.005	-	-	0.005	CWQG-PAL
Fluoride	mg/L	2.8	0.12	-	-	2.8	SSWQO
Nitrate	mg-N/L	-	2.93	-	-	2.93	CWQG-PAL
Nitrite	mg-N/L	-	0.06	-	-	0.06	CWQG-PAL
Total ammonia	mg-N/L	-	1.79[(a)]	-	-	1.79[(a)]	CWQG-PAL
Aluminum	µg/L	-	100[(b)]	-	-	100[(b)]	CWQG-PAL
Arsenic	µg/L	25	5	-	-	25	SSWQO
Barium	µg/L	-	-	-	1000	1000	BC ENV 2018
Boron	µg/L	-	1,500	-	-	1,500	CWQG-PAL
Cadmium	µg/L	-	0.04[(c)]	-	-	0.04[(c)]	CWQG-PAL
Chromium	µg/L	-	1.0[(d)]	-	-	1.0	CWQG-PAL
Cobalt	µg/L	-	-	0.78[(e)]	-	0.78[(e)]	FEQG
Copper	µg/L	-	2[(f)]	-	-	2[(f)]	CWQG-PAL
Iron	µg/L	1,060	300	-	-	1,060	SSWQO
Lead	µg/L	-	1[(g)]	-	-	1[(g)]	CWQG-PAL
Mercury	µg/L	-	0.026	-	-	0.026	CWQG-PAL
Molybdenum	µg/L	-	73	-	-	73	CWQG-PAL
Nickel	µg/L	-	25[(h)]	-	-	25[(h)]	CWQG-PAL
Selenium	µg/L	-	1	-	-	1	CWQG-PAL
Silver	µg/L	-	0.25	-	-	0.25	CWQG-PAL

Table 12.2-1: AEMP Benchmarks for Evaluating the Potential for Toxicological Impairment of Aquatic Life

Parameter	Unit	SSWQO	CWQG-PAL	FEQG	Other Source	Selected AEMP Benchmark	Source
Strontium	µg/L	-	-	-	30,000	30,000	Pacholski 2009
Thallium	µg/L	-	0.8	-	-	0.8	CWQG-PAL
Uranium	µg/L	-	15	-	-	15	CWQG-PAL
Vanadium	µg/L	-	-	120(i)	-	120	FEQG
Dissolved zinc	µg/L	-	5.6	-	-	5.6(j)	CWQG-PAL

(a) Total ammonia guideline is pH and temperature dependent. The guideline shown is based on median baseline pH and a water temperature of 11°C (median in 2018 Near-field area). Median/mean Near-field area pH and temperature will be used to derive the AEMP benchmark for Action Level assessment.

(b) Total aluminum guideline is pH dependent. The guideline shown is based on the median baseline pH (7.63). Median/mean Near-field area pH will be used to derive the AEMP benchmark for Action Level assessment.

(c) The cadmium guideline is hardness dependent and can be calculated using the equation: 10^(0.83*(log[hardness])-2.46). Value shown is based on a median baseline hardness (20.7 mg/L as $CaCO_3$). Median/mean Near-field area hardness will be used to derive the AEMP benchmark for Action Level Assessment.

(d) Guideline is for hexavalent chromium.

(e) The cobalt guideline is hardness dependent and can be calculated using the equation: exp{(0.414[ln(hardness)] – 1.887}. This equation is validated within a range of hardness values between 52 and 396 mg/L. The benchmark value shown in the table is based on a hardness of 52 mg/L as $CaCO_3$, because the median baseline hardness is lower than the validated range (i.e., 20.7 mg/L as $CaCO_3$). For Action Level assessment, the median/mean Near-field area hardness will be used to derive the AEMP benchmark. Source: Environment Canada. 2017. Canadian Environmental Protection Act, 1999, Federal Environmental Quality Guidelines, Cobalt. Environment Canada. May 2017.

(f) The copper guideline is hardness dependent; at hardness less than 82 mg/L as $CaCO_3$, the guideline is 2 µg/L. Median/mean Near-field area hardness will be used to derive the AEMP benchmark for Action Level assessment.

(g) The lead guideline is hardness dependent; at hardness less than or equal to 60 mg/L as $CaCO_3$, the guideline is 1 µg/L. Median/mean Near-field area hardness will be used to derive the AEMP benchmark for Action Level assessment.

(h) The nickel guideline is hardness dependent; at hardness less than or equal to 60 mg/L as $CaCO_3$, the guideline is 25 µg/L. Median/mean Near-field area hardness will be used to derive the AEMP benchmark for Action Level assessment.

(i) Source: Environment and Climate Change Canada (ECCC). 2016. Canadian Environmental Protection Act, 1999, Federal Environmental Quality Guidelines, Vanadium. Environment and Climate Change Canada. May 2016.

(j) The zinc guideline is pH, hardness and DOC dependent. The guideline shown is based on the median baseline field pH (7.63) and DOC (2.28 mg/L), and the lowest hardness in the validated range for the guideline (i.e., 23.4 mg/L as $CaCO_3$) because median baseline hardness was lower (i.e., 20.7 mg/L as $CaCO_3$). For Action Level assessment, the median/mean Near-field area hardness, pH, and DOC will be used to derive the AEMP benchmark.

(k) The sulphate guideline is hardness dependent. The guideline shown is based on the lowest hardness in the validated range for the guideline (i.e., 0 to 30 mg/L as $CaCO_3$) to match median baseline hardness in Meliadine Lake (i.e., 20.7 mg/L as $CaCO_3$). Source: BC ENV 2018.

SSWQO = Site-specific Water Quality Objective; CWQG-PAL = Canadian Water Quality Guideline for the Protection of Aquatic Life; FEQG = Federal Environmental Quality Guideline; AEMP = Aquatic Effects Monitoring Program.

12.2.1.3 Toxicological Impairment – Human Consumption

The revised low Action Level for human consumption of water is as follows, based on combination of comparisons of concentrations between the Near-field and reference areas, comparisons to AEMP benchmarks and the normal range, and evaluation of differences temporal trends between reference and exposure areas:

- concentration in Near-field area is significantly greater compared to the reference areas, and greater than the normal range
- concentration in Near-field area exceeds 75% of the AEMP benchmark of the Canadian drinking water quality guideline or aesthetic objective
- a divergence of trends in concentration is observed between the Near-field and reference areas

Each condition must be met for the low Action Level to be triggered. This evaluation is conducted for the parameters listed in Table 12.2-2, which lists available drinking water guidelines and objectives. If this low Action Level is reached, then it is expected that formal human health and/or ecological risk assessments may be needed to evaluate the safety of water for consumption.

Table 12.2-2: Drinking Water Benchmarks for Evaluating the Potential for Impairment of Water Quality for Human Consumption

Parameter[a]	Unit	Drinking Water Objectives and Guidelines[b]		Selected AEMP Benchmark
		Aesthetic Objectives	Water Quality Guidelines	
pH	-	7.0 to 11	-	7.0 to 11
Total dissolved solids	mg/L	500	-	500
Chloride	mg/L	250	-	250
Cyanide (free)	mg/L	-	0.2	0.2
Fluoride	mg/L	-	1.5	1.5
Sodium	mg/L	200	-	200
Sulphate	mg/L	500	-	500
Nitrate	mg-N/L	-	10	10
Nitrite	mg-N/L	-	1	1
Antimony	µg/L	-	6	6
Arsenic	µg/L	-	10	10
Barium	µg/L	-	1000	1000
Boron	µg/L	-	5000	5000
Cadmium	µg/L	-	5	5
Chromium	µg/L	-	50[c]	50
Copper	µg/L	1,000	-	1,000
Iron	µg/L	300	-	300
Lead	µg/L	-	10	10
Manganese	µg/L	50	-	50
Mercury	µg/L	-	1	1
Selenium	µg/L	-	50	50
Uranium	µg/L	-	20	20
Zinc	µg/L	5,000	-	5,000

(a) Water temperature has an aesthetic objective as per Health Canada (2017) but was excluded from this list.
(b) Source = Health Canada (2017) Canadian Drinking Water Quality Guidelines - Summary Table.
(c) Guideline is for hexavalent chromium.

12.2.1.4 Nutrient Enrichment – Water Quality

Nutrient enrichment in the receiving environment will be evaluated using a combination of comparisons of concentrations between the Near-field and reference areas, comparisons to AEMP benchmarks and the normal range, and evaluation of differences temporal trends between reference and exposure areas.

Water quality parameters to be assessed for this component are TP (i.e., the limiting nutrient in Meliadine Lake) and chlorophyll *a* (i.e., a direct indicator of primary productivity used in trophic status assessment).

The revised low Action Level for this component has three conditions:

- concentration in Near-field area is significantly greater compared to the reference areas, and greater than the normal range
- concentration in Near-field area exceeds 75% of the AEMP benchmark
- a divergence of trends in concentration is observed between the Near-field and reference areas

Each condition must be met for the low Action Level to be reached.

The AEMP benchmarks proposed for nutrient enrichment were selected to protect the oligotrophic status of Meliadine Lake and represent the commonly accepted upper limits of the oligotrophic ranges for TP and chlorophyll *a*. For TP, the benchmark is 0.01 mg/L based on CCME (2004) trigger ranges for evaluating trophic status in lakes. For chlorophyll *a*, the benchmark is 4.5 µg/L, based on an evaluation of chlorophyll *a* concentration in relation to trophic status by DDMI (2013), which concluded that based on scientific literature on trophic boundaries for chlorophyll *a*, 4.5 µg/L represents a reasonable and conservative upper boundary for oligotrophic status for northern lakes, although aesthetic qualities are likely to be preserved at chlorophyll *a* concentrations up to 10 µg/L.

12.2.2 Action Level Assessment for the 2018 AEMP Results in Meliadine Lake

This section provides a summary of comparisons of the 2018 AEMP results to Low Action Levels specified above and in Section 8 of the AEMP Design Plan (Golder 2016a). Results of Action Level comparisons are organized in this section according to the two impact hypotheses: toxicological impairment and nutrient enrichment.

12.2.2.1 Toxicological Impairment

The following components of the aquatic environment were evaluated in 2018 to identify toxicological impairment:

- end of pipe toxicity (Section 2.4.2.2)
- water quality in Meliadine Lake (protection of aquatic life and human consumption; Section 6.0)
- benthic invertebrate community (Section 9.0)

Based on the 2018 AEMP results, Low Action Levels for toxicological impairment were not triggered for any components. Additional discussion of each component is provided below.

End of Pipe Toxicity

Persistent sublethal toxicity was not observed in the same test organisms in three consecutive end-of-pipe samples.

Water Quality in Meliadine Lake

The three Low Action Level criteria were not met for toxicologically relevant parameters. Therefore, the Low Action Level for toxicological impairment was not triggered.

All median and mean concentrations in the Near-field area of toxicologically relevant parameters with AEMP Benchmarks were less than 75% of AEMP benchmarks. Therefore, the second condition of the low Action Level was not met for parameters with available benchmarks.

Concentrations of two parameters with no aquatic life benchmarks (total lithium and manganese) in the Near-field area were significantly greater than in the reference areas, and greater than the normal range in 2018. The Near-field area concentration of lithium (1.5 µg/L) was less than five times the analytical DL (0.5 µg/L), which is within the range of analytical uncertainty. Therefore lithium was not considered further in the Action Level assessment. Total manganese concentration in the Near-field area (6 µg/L) was greater than five times the DL (0.05 µg/L) and the magnitude of difference relative to the reference area for manganese was slightly greater than two-fold (Near-field area: 6 µg/L; pooled reference areas: 2.7 µg/L). Because of the small difference between the Near-field and reference area concentrations, and the uncertainty of whether it represents a current effect of the Mine discharge or a persisting effect from the pre-construction period (see below), it is recommended that observed difference for this parameter in 2018 be confirmed during the 2019 AEMP before consideration in the Action Level Assessment.

The Mine has only been discharging for one year, and therefore a temporal trend due to mine effluent discharge cannot be determined. As demonstrated in Appendix 6B, specific conductivity and concentrations of several major ions have been increasing the Near-field area since 2015 (i.e., beginning prior to Mine discharge). The increasing ion concentrations may be related to the input of greywater and treated sewage to Meliadine Lake west of the Near-field area from 2007 to 2017 (see Section 2.6). Because of the monotonic increase observed in the Near-field area since 2015, data post-2015 were not included in the Normal Range calculations, and therefore, it is expected the Near-field area concentrations would be higher than Normal Range for these parameters. With the diversion of STP discharge to CP1, and subsequent treatment in the EWTP prior to discharge through the CP1 diffuser, it is anticipated that, if treated sewage was the source of the increased ions in the Near-field area, then the major ions concentrations will either stabilize or decline in future years. The 2019 AEMP will investigate this possibility.

Finally, as stated above, there is only one year of Mine discharge from CP1 diffuser to the Near-field area, so divergence of trends compared to the reference areas cannot be assessed. As stated in Appendix 6B, the increase in specific conductivity and major ion concentrations in the Near-field and possibly Mid-field area over the past three years has not been observed in the reference areas. Future AEMPs will evaluate whether Near-field area concentrations continue to increase relative to reference areas.

Benthic Invertebrate Community

As indicated in Section 9.6, the Low Action Level for toxicological impairment was not triggered by the 2018 AEMP benthic invertebrate results.

No decreases were observed in 2018 beyond the normal range in the Near-field area in density, richness or densities of dominant taxa. Some divergence of trends in density, richness and dominant taxa were observed compared to the reference area; however, differences in trends observed between the Near-field area and reference areas more likely reflect differences in habitat variation (primarily particle size) as discussed further in Section 9.4.3. That is, these differences among sampling areas were likely due to pre-discharge differences in sediment composition (i.e., not Mine-related) that are accounted for by the normal ranges developed for the AEMP.

12.2.2.2 Nutrient Enrichment

The following components of the aquatic environment were evaluated in 2018 to identify nutrient enrichment:

- water quality in Meliadine Lake (nutrients from Section 6.0 and chlorophyll *a* from Section 11.0)
- benthic invertebrate community (Section 9.0)

Based on the 2018 AEMP results, Low Action Levels for nutrient enrichment were not triggered for any components. Additional discussion of each component is provided below.

Water Quality in Meliadine Lake

The three Low Action Level criteria were not met for TP and chlorophyll *a*. Therefore, the Low Action Level for nutrient enrichment was not triggered.

Median chlorophyll *a* concentration in the Near-field area was higher than the normal range and significantly higher compared to the reference areas. Median TP concentration in the Near-field area was within the normal range and significantly higher only compared to the Reference Area 2. There is evidence of a gradient in primary productivity in Meliadine Lake, with the highest chlorophyll *a* level in the Near-field area. In addition, TSI based on chlorophyll *a* concentration was highest in the Near-field area, followed by the Mid-field area, and lowest in the three reference areas. The pattern in chlorophyll *a* concentrations among sampling areas in 2018 was similar to that observed in previous years.

Mean TP (based on depth-integrated samples) and chlorophyll *a* concentrations were 0.0049 mg/L and 1.91 µg/L in the Near-field area, respectively. These mean values are below the Action Level criterion of 75% of the applicable benchmark values (i.e., TP: 0.0075 mg/L; chlorophyll *a*: 3.38 µg/L).

Phytoplankton biomass and chlorophyll *a* in the Near-field area in 2018 were within the range of results observed in previous years, suggesting that potential nutrient enrichment may have began prior to initiation of Mine construction (i.e., from the exploration camp STP discharge). As stated above, it is anticipated that if treated sewage from the exploration camp was the source of nutrients to the Near-field area, then the diversion of STP discharge to CP1 and subsequent treatment in the EWTP prior to discharge through the CP1 diffuser may either stabilize or decline nutrient concentrations and effects on phytoplankton biomass and chlorophyll *a* in future years. In addition, the Mine has only been discharging for one year, and therefore a temporal trend due to Mine effluent discharge cannot be determined. Future AEMPs will evaluate whether Near-field area nutrient and chlorophyll *a* concentrations continue to increase relative to reference areas.

Benthic Invertebrate Community

As indicated in Section 9.6, the Low Action Level for nutrient enrichment was not triggered by the 2018 AEMP benthic invertebrate results.

No increases were observed in 2018 beyond the normal range in the Near-field area in density, richness or densities of dominant taxa. Some divergence of trends in density, richness and dominant taxa were observed compared to the reference area; however, differences in trends observed between the Near-field area and Reference areas may be influenced by differences in habitat variation (primarily particle size) as discussed further in Section 9.4.3. That is, these results among sampling areas were likely due to pre-discharge differences in sediment composition (i.e., not Mine-related) that are accounted for by the normal ranges developed for the AEMP.

12.2.3 Integrated Summary

Volume 7 of the FEIS for the Meliadine Gold Project (Mine) predicted inputs of nutrients, metals, and major ions to Meliadine and Peninsula Lakes. It was predicted that these inputs would result in minor changes to water and sediment quality in Meliadine Lake, and that any corresponding effects on fish and fish habitat would be negligible (Agnico Eagle 2014). The component sections of the annual AEMP report are designed to characterize changes in measures related to contaminant and nutrient input, and related responses in phytoplankton, benthos, and fish. The purpose of the integrated summary is to synthesize the results for each component to evaluate the overall direction of change to the aquatic ecosystem. The objective of the synthesis is to:

- integrate AEMP findings from all components
- determine the strength of support for each impact hypothesis and effects on the ecosystem
- support decision making for management responses

The integrated summary is part of the overall objective of the AEMP to assess potential mine-related effects on the aquatic ecosystem and to meet regulatory requirements outlined in the Type A Water License (2AM-MEL1631) and MDMER, while also meeting commitments made during the environmental permitting process. The specific objectives of the AEMP are to:

- determine the short- and long-term effects of the Project on the aquatic receiving environment
- evaluate the accuracy of predictions made in the FEIS, including the final significance statements regarding impact to the aquatic ecosystem
- assess the efficacy of planned mitigation incorporated into the Project design
- collect data required to identify the need for potential additional mitigation of Project effects within a management response framework

The 2018 AEMP program consisted of water quality, sediment quality, benthic invertebrate community, and a phytoplankton targeted study in Meliadine Lake, and water quality monitoring in selected peninsula lakes. The 2018 fish health survey was implemented to meet EEM sampling requirements and was not intended to meet the specific requirements of the Mine's AEMP fish health component (Section 10.1). However, the 2018 fish health results are discussed as part of this integrated summary to evaluate potential mine-related effects on biological components, with the understanding that the 2018 fish program was not designed to answer the key questions from the AEMP. The next AEMP fish health and fish tissue chemistry program is scheduled for 2021.

The results of the 2018 AEMP in Meliadine Lake and the Peninsula Lakes (water quality and phytoplankton only) were evaluated in the context of the key questions proposed for each core component in the AEMP Design Plan (Golder 2016a). The key questions and a summary of the results for each component are presented in Table 12.2-3 and discussed below. The results of the effluent chemistry and toxicity testing program are also discussed in the context of the results of the AEMP components, where relevant.

Peninsula Lake Summary and Conclusions

Changes in some water quality parameters over time were observed in Lakes A8, B7, and D7. However, all parameter concentrations were less than their respective water quality guidelines, were within normal ranges, and aligned with FEIS predictions. The water quality dataset for peninsula lakes for the pre-construction and construction phase was limited, and potential factors accounting for temporal trends were not identified in

this report. A phytoplankton targeted study was also conducted in Peninsula Lakes in 2018 with collection of chlorophyll *a* data. No findings of significance were identified as part of the 2018 phytoplankton study of the Peninsula Lakes.

Meliadine Lake Summary

Potential mine-related changes in water quality in Meliadine Lake were observed in the Near-field area in 2018 for specific conductivity, TDS, hardness, several major ions, and a number of total metals; concentrations exceeded the upper bound of their respective normal range and increased in the Near-field and relative to reference areas over time. Water Licence exceedances in the effluent were observed for TDS and total aluminum. However, the exceedance of total aluminum WL limit occurred only in one sample, with other effluent samples noticeably lower in concentration, suggesting that the measured value may be anomalous. In addition, although total aluminum concentrations were higher in the Near-field area, there was no indication of declining concentrations with distance from the diffuser. Concentrations of a few metals in bottom sediments exceeded the upper bound of their respective normal range, but exceedances were marginal and sediment metal concentrations in the Near-field area did not increase relative to the reference areas over time. Concentrations of sediment quality parameters were less than their respective guidelines, with the exception of sediment arsenic, copper, and chromium. However, arsenic, copper, and chromium concentrations in Near-field sediments were within the upper bound of their respective normal ranges. Overall, water and sediment quality in 2018 was generally consistent with FEIS predictions.

The 2018 AEMP results indicated that the benthic community was not measurably affected by potential Mine-related changes in water or sediment quality in Meliadine Lake. Lower density and BCI values were observed in the Near-field area (relative to pooled reference areas), but values were within the normal range. Therefore, differences among these areas may be attributed to pre-discharge differences in sediment composition and natural spatial variation. Effects on fish health were not observed in 2018. There was a statistically significant difference female condition in the Near-field area relative to Reference Area 1. However, the magnitude of difference on female condition did not exceed the 10% critical effect size and a similar difference was not observed in supporting energy storage endpoints. The comprehensive AEMP fish health program was not conducted in 2018 and so an evaluation of fish tissue was not conducted.

Low Action Levels for toxicological impairment or nutrient enrichment were not triggered by the 2018 AEMP results.

Meliadine Lake Conclusions

The results of the water quality monitoring program suggest a Mine-related effect on water quality in the Near-field and Mid-field areas. Baseline (pre-2015) and pre-construction and construction phase (2015 to 2017) water quality data were evaluated as part of the normal range screening (Appendix 6B). The assessment indicated a change in major ion concentrations in the Near-field area, and a potential change in the Mid-field area in the 2015 to 2017 data, relative to pre-2015 data collected periodically between 1995 and 2013 in Meliadine Lake.
This evaluation, in combination with the qualitative temporal analysis conducted as part of the 2018 AEMP water quality program (Section 6.4.5), suggest a potential pre-construction effect on water quality, as well as a potential effect on water quality for selected parameters during treated mine effluent discharge in 2018. However, the changes in water quality in Meliadine Lake were within the conditions predicted by FEIS. Mine-related effects on sediment quality were not observed in 2018.

Observed changes in key water quality parameters in 2018 did not translate into effects in the biological components in 2018, with respect to major ions and total metals. However, the nutrient enrichment effect observed in prior AEMP monitoring years continued to be observed in some biological components in 2018. A phytoplankton targeted study was conducted as part of the 2018 AEMP monitoring program; this program is not a formal component under the AEMP Design Plan (Golder 2016a). Higher chlorophyll *a* concentrations and phytoplankton biomass, and unique phytoplankton community structure were observed in the Near-field area (relative to Mid-field and reference areas), indicating potential nutrient enrichment originating from the exploration camp STP discharge. Chlorophyll *a* and phytoplankton biomass were within the ranges observed during the pre-construction phase of the Mine, suggesting that nutrient enrichment may have begun prior to the discharge of treated mine effluent from MEL-14.

Mine-related effects on the benthic invertebrate community were not observed in 2018. However in 2016, mean density fell outside of the upper bound of the normal range in the Near-field area, potentially due to the influence of exploration camp STP discharge. Total phosphorus loadings approximately doubled in treated sewage effluent in 2016 (corresponding to an increase in Mine population), and held steady in 2017, prior to declining in 2018 (Section 2.6.2). TP loadings did not correspond to observed spatial or temporal TP water quality trends in the Near-field area but median TP concentrations were slightly elevated in 2016 and 2017, relative to 2015 and 2018. A statistically significant difference in female condition factor was observed during the fish health program, which also aligns with potential nutrient enrichment in the Near-field area, however, the magnitude of the difference was within the CES.

Overall, nutrient enrichment in Meliadine Lake may have begun in 2016 with expansion of the Mine population and increased STP nutrient loading into the lake. Effects observed in phytoplankton, benthos and fish biological components are consistent with mild nutrient enrichment. Although effects in benthos were not observed in 2018, effects on phytoplankton were evident in the Near-field area despite a reduction in sewage TP loadings; TP loadings in 2018 were lower relative to 2016/2017 loadings and relative to baseline (i.e., 2013 and 2015). Additionally in 2018, a stimulatory effect on freshwater algae growth (*Pseudokirchneriella subcapitata*) was observed during sublethal toxicity testing with effluent; this further supports the potential for nutrient enrichment in Meliadine Lake as a result of Mine effluent discharge. Lastly, increased major ion and some total metal concentrations in lake water in the Near-field area were observed, and are indicative of a Mine-related effect.

Similar to nutrient enrichment, major ion concentrations and increases in selected total metal concentrations were observed in the Near-field area during pre-construction and continued to increase during the construction phase. It is likely that the exploration camp STP discharge contributed to increases in these parameters. However, concentrations are within the range of FEIS predictions and have not translated into increased concentrations in the sediment, or effects on biological components. Future AEMP monitoring programs will continue to monitor for spatial and temporal trends.

Table 12.2-3: A Summary of the 2018 AEMP Results by Component in the Context of the Key Questions

Component	Key Question	Summary
Peninsula Lakes		
Water Quality	Are concentrations of key parameters in peninsula lakes consistent with FEIS predictions and less than AEMP benchmarks?	• Concentrations of key parameters were below AEMP benchmarks • Water quality in Peninsula Lakes was outside the normal range for selected total metals • Water quality in the Peninsula Lakes was generally consistent with FEIS predictions
	Are concentrations in peninsula lakes increasing over time relative to baseline or reference conditions?	• Increasing concentrations over time for selected parameters were identified in Lakes A8, B7, and D7
Meliadine Lake		
Water Quality	Are concentrations of key parameters in effluent less than Water Licence Limits?	• Key parameter concentrations were below Water Licence Limits, except for total dissolved solids (one sample) and total aluminum (one sample) • Effluent was not acutely toxic to Rainbow Trout
	Are concentrations of key parameters in Meliadine Lake consistent with FEIS predictions and less than AEMP Action Levels?	• Water quality in the Near-field area was generally consistent with FEIS predictions • Concentrations of key parameters in the Near-field area did not trigger the Low Action Level
	Are concentrations in the exposure area increasing over time relative to the reference areas?	• Increasing concentrations over time in the Near-field area in 2018 and relative to temporal variation in reference areas were identified for specific conductivity, hardness, TDS, major ions, organics, and selected total metals. • Observed changes suggest a potential mine-related effect on water quality in the Near-field and Mid-field areas but conditions are within the range predicted by FEIS.
Sediment Quality	Are concentrations of sediment quality parameters in Meliadine Lake greater than benchmarks?	• Concentrations of arsenic, copper, and chromium exceeded Interim Sediment Quality Guidelines • Normal range exceedances occurred in the Near-field area for aluminum, beryllium, cadmium, nickel, silver, thallium, and zinc, and in the Mid-field area for copper.
	Are concentrations in the exposure area increasing over time relative to the reference areas?	• Increasing concentrations over time in the Near-field area in 2018 were identified for select metals but these metals either did not or only slightly exceeded their normal ranges.
Benthic Invertebrate Community	Is the benthic invertebrate community affected by potential Mine-related changes in water and sediment quality in Meliadine Lake?	• Benthic invertebrate communities in the Near-field area had significantly lower density and BCI values (relative to Reference area 3 median) compared to pooled reference areas. However, all mean 2018 AEMP variables for both exposure and reference areas sampled in Meliadine Lake were within their respective normal ranges in the Near-field area • Mine-related effects on the benthic invertebrate community were not observed in 2018

Table 12.2-3: A Summary of the 2018 AEMP Results by Component in the Context of the Key Questions

Component	Key Question	Summary
Fish Health	Is fish health affected by changes in water and sediment quality in Meliadine Lake?[(a)]	• An effect was observed in female condition, which was 6% greater in the Near-field area than Reference area 1. The magnitude of effect was below the 10% critical effect size, and a similar difference was not observed in supporting energy storage endpoints
Fish Tissue Chemistry	Are tissue metal concentrations in fish from Meliadine Lake increasing due to mining activities?	Not assessed as part of the 2018 AEMP and not required under the 2018 EEM program.
	Are tissue metal concentrations in fish from Meliadine Lake increasing relative to reference areas or baseline?	

(a) Fish health was not included as a component of the 2018 AEMP program but is included in the integrated summary to evaluate potential mine-related effects on the biological components.

AEMP = Aquatic Effects Monitoring Program; EEM = Environmental Effects Monitoring; BCI = Bray-Curtis Index; TDS = total dissolved solids; FEIS = Final Environmental Impact Statement.

12.3 Future Monitoring Timelines

12.3.1 EEM

The Cycle 2 EEM Interpretative Report is required to be submitted to the Minister of Environment no later than 36 months after the day on which the previous interpretative report was required to be submitted. As the previous interpretative report was due on June 21, 2019, the next interpretative report is due on or before June 21, 2022. The timelines for the next EEM cycle are provided in Table 12.3-1.

Table 12.3-1: Timelines for the Cycle 2 EEM Study

Item	Timeline Description	Tentative Execution/ Submission Date
Cycle 2 EEM Study Design	At least six months prior to the biological monitoring field program	February 2021
Field Program	At least six months after submission of Study Design	August 2021
Cycle 2 EEM Interpretative Report	Not later than 36 months after the day on which the previous interpretative report was required to be submitted	June 21, 2022

12.3.2 AEMP

The AEMP is an annual program required by the Water Licence, and therefore, the AEMP will be conducted in 2019. As per the AEMP Design Plan, the water quality components in Meliadine Lake and the Peninsula Lakes are conducted annually. Water quality sampling will be conducted in the Near-field and Mid-field areas once in the under-ice season and monthly in the open-water season during mine effluent discharge; monthly in the open-water season in Reference Area 1 during mine effluent discharge; and once in Reference Areas 2 and 3 in the open-water season. Biological monitoring studies of BIC (with supporting sediment quality), fish health, and fish tissue chemistry will be conducted concurrently with the next EEM cycle, which is planned for August 2021.

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

GLOSSARY

Term	Definition
Abundance	The number or quantity of cells or organisms in a particular area or volume of sample.
Alkalinity	A measure of the acid-neutralizing capacity carbonates, bicarbonates and hydroxides present in water. Alkalinity is typically reported in units of mg/L calcium carbonate ($CaCO_3$).
Aquatic Effects Monitoring Program	A monitoring program designed to evaluate the effect of mining activities and mitigation on the aquatic environment.
Benthic Invertebrates	Aquatic animals without backbones (e.g., insects, worms, snails, clams, crustaceans) that live on/in the bottom substrate of a waterbody.
Biomass	The mass of all the cells or organisms in a particular area or volume of sample.
Bray-Curtis index	An index used to summarize the overall difference in community structure between reference and exposure areas.
Canadian Water Quality Guidelines for the Protection of Aquatic Life	Guidelines established by the Canadian Council of Ministers of the Environment to protect aquatic life (i.e., fish, aquatic plants, and benthic invertebrates) in Canadian surface waters.
Chlorophyll *a*	A photosynthetic pigment found in plants, responsible for the conversion of inorganic carbon and water into organic carbon. The concentration of chlorophyll *a* is often used as an indicator of algal biomass.
Community	The groups of organisms living together in the same area, usually interacting or depending on each other for existence.
Community composition	The species present and their relative proportions in an assemblage of organisms.
Condition	A measure of the energetic status of fish.
Dominance	The predominance of one or more species in a community.
Drinking Water Quality Guidelines	Health Canada guidelines used to evaluate the suitability of water for human consumption.
Effluent	The out-flow water or wastewater from a water processing system or device, or the final water which is discharged from a treatment plant. For purposes of this document, effluent is the water that is discharged from the water treatment plant to Meliadine Lake.
Ekman grab	A sampling device used to collect a discrete sample of bottom sediment.
Environmental effects monitoring	A science-based performance measurement tool used to evaluate the adequacy of effluent regulation in protecting fish, fish habitats and the usability of fisheries resources
Euphotic zone	The extent of the water column that is exposed to sufficient sunlight for photosynthesis to occur (typically to a depth in the water column where 1% of the irradiance is measured, or two times the Secchi depth).
Exposure area	An area that receives direct discharge from mining activities.
Fecundity	The number of eggs ripening between current and next spawing period in a female (Bagenal and Tesch, 1978).
Homogeneity of variance	Statistical term for the assumption that the variance within each of the groupings/populations is equal.
Inhibition concentration at 25%	The concentration that results in a 25% reduction of a non-lethal endpoint, such as reproduction or growth, in a given time period.
in situ	Refers to measurements or data recorded in the field, at the sampling site.
Interim Sediment Quality Guidelines	In reference to the Canadian sediment quality guidelines (CCME 2001), the concentration above which adverse effects may occur, and below which they are not expected to occur.

Term	Definition
Kemmerer	A plastic or Teflon water sampling device that is opened, lowered into the water to the desired sample collection depth; a weighted messenger device is used to close the Kemmerer and sample water from the desired depth.
Mean	Arithmetic average value.
Metalloid	A class of chemical elements intermediate in properties between metals and non-metals; e.g., arsenic and boron.
Median lethal concentration	The concentration that results in death of 50% of the test population
Metals	A class of chemical elements that are good conductors of electricity and heat and have the capacity to form positive ions in solution; e.g., aluminum, copper, iron, and zinc.
Normal Range	An estimate of natural variability.
Nutrients	Substances (elements or compounds) such as nitrogen or phosphorus, which are necessary for the growth and development of plants and animals.
Nutrient Enrichment	The type of effect resulting from an increase in the nutrients to an ecosystem, which may impact primary productivity.
Oligotrophic	Trophic state classification for lakes characterized by low concentration of nutrients and low organic productivity. OligotrophicTrophic state classification for lakes characterized by low concentration of nutrients and low organic productivity.
Otolith	A calcified structure that can be used to estimate fish age.
P–value	Statistical value used to determine the significance of a relationship or difference, e.g., $P < 0.1$.
Parameter	A particular physical, chemical, or biological property that is being measured.
pH	The negative logarithm of the concentration of the hydronium ion (H^+). The pH is a measure of the acidity or alkalinity of an aqueous solution, expressed on a scale from 0 to 14, where 7 is neutral, values below 7 are acidic, and values over 7 are alkaline.
Phytoplankton	Small, free-floating algae that are suspended in the water column.
Probable Effects Level (PEL)	Canadian sediment quality guideline for the protection of freshwater quality life (CCME 2001), representing the concentration above which adverse effects may but will not always occur.
R^2	A coefficient of determination, a statistical measure of how well a regression line approximates the real data points.
Reference area	An area that is reasonably similar in terms of monitored components and features to the exposure area, though not necessarily identical, but has no potential to be affected by the mine.
Richness	The number of different taxonomic groups present in a given area or sample volume.
Secchi Depth	A parameter used to determine the clarity of surface waters. The measurement is made with a Secchi disk, a black and white disk that is lowered into the water and the depth is recorded at which it is no longer visible. Higher Secchi depth readings indicate clearer water that allows sunlight to penetrate to a greater depth. Lower readings indicate turbid water that can reduce the penetration of sunlight. Limited light penetration can be a factor in diminished aquatic plant growth beneath the surface, thus reducing the biological re-aeration at greater depths.
Sediment	Solid material that is transported by, suspended in, or deposited from water. It originates mostly from disintegrated rocks; it also includes chemical and biochemical precipitates and decomposed organic material.
Standard deviation (SD)	A measure of the variability or spread of the measurements about the mean. It is calculated as the positive square root of the variance.
Simpson's Diversity Index	A measure of the number of taxonomic groups or species present within an area of habitat or in a sample, as well as the abundance of each of those groups. Index values range from 0 to 1; the greater the diversity, the greater the index value.

Term	Definition
Standard error (SE)	The standard deviation (positive square-root of the variation) of the errors associated with a series of measurements.
Simpson's Evenness Index	A measure of how evenly the total invertebrate density is distributed among the taxa in an area or sample. Index values range from 0 to 1; higher numbers indicate a greater equality among all taxa present in a sample and low values represent low evenness (i.e., a high degree of dominance by one or a few organisms).
