Appendix H SBR Mechanical Plant Operating Cost Data

Cost and Performance Evaluation of BNR Processes

Gerald W. Foess, Paul Steinbrecher, Kenneth Williams, and George S. Garrett

he use of biological nutrient removal (BNR) processes is expected to increase in Florida because of growing concerns about the effects of nitrogen and phosphorus on the stimulation of undesirable aquatic growth in surface waters and the potential adverse health effects of nitrates in groundwater.

In the Florida Keys, degradation and eutrophication of canal and near shore waters led Monroe County to require all new and expanding wastewater treatment facilities to meet Advanced Wastewater Treatment (AWT) or Best Available Technology (BAT). However, the county lacked the information it needed to determine what discharge limitations could reasonably be imposed under these requirements, given the large number (nearly 300) of wastewater treatment plants with small flows and limited operational oversight. Experience had demonstrated that DEP AWT limits of 3 mg/L for nitrogen and 1 mg/L for phosphorus could be achieved by large plants, but there was no assurance or expectation that such stringent limits could be achieved by small plants. Additionally, no specific BAT standards existed.

A study was commissioned by Monroe County, with support and financial assistance from DEP, to determine BAT effluent limitations for treatment plants with permitted design capacities in the range of 2,000 to 100,000 gpd. The summary provided in this article includes a review and ranking of BNR technologies and proprietary equipment on the market with respect to costs, performance, and other factors. Information was derived from equipment suppliers, DEP and EPA databases, technical literature, and visits to operating facilities.

$Small-Flow \, Nutrient \, Removal \, Facilities \, in \, the \, U. \, S. \,$

Table 1 contains a nationwide list of fullscale facilities in the 2,000 to 100,000 gpd range that are designed to meet total nitrogen or phosphorus limits, as derived from DEP and EPA databases and input from 85 equipment suppliers. The most common phosphorus limit is 1.0 mg/L, ranging from 0.1 to 2.0. The most common nitrogen limit is 10 mg/L, ranging from 3 to 14. Florida has imposed the most stringent nitrogen limits on plants in this size range.

Site Visits

Nutrient removal systems in the size range of 2,000 to 100,000 gpd are almost universally furnished as pre-engineered, factory- or field-assembled package systems. Approximately 25 systems available on the market were evaluated, followed by visits to 17 operating treatment plants in Florida, New York, New Jersey, and Massachusetts. The plants represented diverse technologies and covered a spectrum of sizes within the range of interest. Information was gathered on plant performance, actual operation and maintenance costs, actual capital costs, and the level of operator staffing. The collected information was subsequently used in the evaluation of

Gerald W. Foess, Ph.D., P.E., and Paul Steinbrecher, P.E., are with CH2M HILL in Deerfield Beach. Kenneth Williams, P.E., is with CH2M HILL in Key West. George S. Garrett is with the Monroe County Marine Resources Department, Marathon.

alternative systems.

Nutrient Removal Systems Evaluated

The following biological nitrogen removal systems, which were considered representative of the diverse technologies on the market and applicable to small treatment systems, were selected and evaluated.

- $1.\ MLE\,(2-Stage)\,Continuous-Flow\,Suspended-Growth\,Process$
- 2. 4-Stage Continuous-Flow Suspended-Growth Process
- ${\it 3. \ 3-Stage \ Continuous-Flow \ Suspended-Growth \ Process}$
- 4. 4-Stage Sequencing Batch Reactor (SBR) Suspended-Growth Process

- 5. 4-Stage Intermittent-Cycle Suspended-Growth Process
- 6. MLE Process followed by Deep Bed Filtration Process
- 7. Submerged Biofilter Process
- 8. Rotating Biological Contactor (RBC) Process

In each case, the recommended method of phosphorus removal was chemical precipitation. In addition, effluent polishing filtration would be provided in each system, except System 6, which already incorporates the deep bed filtration process for nitrogen removal.

Table 2 presents a description of each system, representative equipment suppliers, and estimated achievable effluent quality. Also included for comparison is a conventional secondary treatment plant (System 9).

Two of the systems identified above (Systems 1 and 6) were determined to be potentially applicable for retrofitting nitrogen $removal \,to\,existing\,WWTPs, and\,evaluated\,separately.\,These\,were$ $identified \, as \, (1) \, System \, 1R-MLE \, (2\text{-Stage}) \, Continuous\text{-} Flow \, Sussible 1 \, Continuous \, (2\text{-Stage}) \, Continuous \, (2\text{-St$ pended-Growth Process, and (2) System 2R—Deep Bed Filtration Process.

The MLE process (System 1R) can be retrofitted to an existing plant by adding an anoxic basin upstream of the existing plant, redirecting the influent flow to this basin, and adding recirculation pumping from the existing aeration basin to the new anoxic basin. Alternatively, an anoxic zone could be created within the existing aeration basin by adding a baffle wall, but that would reduce the capacity of the plant. New chemical feed facilities for phosphorus removal could also be added.

In System 2R, a deep-bed filter would be added downstream of the existing package plant, replacing any existing filtration facilities. New pumping facilities to pump secondary effluent to the deep bed filter would be required, as well as methanol feed facilities and chemical feed facilities for phosphorus removal.

Performance Comparison

As indicated in Table 2, all of the systems are generally considered capable of meeting effluent BOD and TSS concentrations similar to large plants. Achievable effluent nitrogen concentrations range from 6 to 12 mg/L, with the 4-stage and 3-stage processes and the deep-bed filtration process (Systems 2. 3, and 6, respectively) being the most effective. Chemical phosphorus removal in all of the alternative systems is expected to achieve effluent limits of 2 mg/L without filtration and 1 mg/L with filtration.

Achievable permit limits for the MLE retrofit system (System 1R) were considered comparable to the corresponding new-plant MLE system (System 1). Achievable permit limits for the deep-bed filtration retrofit system (System 2R) were also estimated to be similar to those for the corresponding new-plant system (System 6), but with a somewhat lesser N removal capability because the retrofit system did not incorporate an MLE process.

As a result of this performance assessment, DEP provided to Monroe County the following BAT limitations (annual average basis) applicable to new and expanding facilities with permitted design capacities of less than 100,000 gpd (source: DEP correspondence to Monroe County Commissioners dated May 12, 1998):

CBOD	10 mg/L
TSS	10mg/L
N	10mg/L
P	l mg/L

Cost Comparison

Tables 3 and 4 compare costs for the nine new-plant and two retrofit alternatives, respectively, for five different treatment ca $pacities. \ The cost summary includes the estimated construction$ $cost, annual\,O\&M\,cost, uniform\,annual\,cost, and\,unit\,cost\,(\$/1.000$ gallons). Uniform annual costs were determined using an interest rate of 6 percent for a 20-year period. The unit cost was determined by dividing the uniform annual cost by the number of 1,000 gallons of wastewater treated per year, at 80 percent capacity utilization.

Construction costs for the new-plant alternatives include all required facilities for a new plant on a new site. Filtration was included for all of the systems except the base case secondary treatment system. In general, the conventional suspended-growth nutrient removal technologies have the lowest construction costs for capacities exceeding approximately 10,000 gpd. The attachedgrowth processes construction costs are competitive at the smallest system sizes of 4,000 and 10,000 gpd. A generally poor correla $tion \, exists \, between \, the \, construction \, cost \, of \, alternatives \, and \, nitrogen \,$ removal performance. - 70,000 gpd.

R2	Deep Bed Denitrification Filter Construction Cost, \$ Annual O&M Cost, \$/yr Uniform Annual Cost, \$/yr Present Worth, \$ Unit Cost, \$/1,000 gal	109,000 17,600 27,100 310,900 31.5	121,000 18,200 28,700 329,800 13.3	147,000 20,300 33,100 379,800 6.1	163,000 24,800 39,000 447,500 3.6	213,000 28,600 47,200 541,000 2.2				

For the retrofit alternatives, only the new facilities needed for nitrogen and phosphorus removal are included. Although the deep bed denitrification filter retrofit alternative provides somewhat better nitrogen removal percentage than the MLE retrofit alternative, it is approximately two to four times more costly, depending on capacity.

O&M costs were developed by individually considering operations labor, electricity, maintenance and repairs materials and labor, solids handling and disposal, administration labor, laboratory analytical requirements, and chemical costs. For the retrofit alternatives, only the increase in these costs associated with the addition of nitrogen and phosphorus removal facilities was estimated. Assumptions were as follows:

- Operations labor labor at \$36/hour (includes overhead), with minimum staffing per F.A.C. 62-699.310
- Electricity-\$0.10/kW-hr

Astronomy Commenced Commen

- Maintenance and repairs materials and labor 3 percent of capital costs/year
- Solids handling and disposal-liquid haul at \$0.17/gal
- Administrative 5 percent of the sum of the operations labor, electricity, and maintenance and repairs costs
- Laboratory commercial rates applied to required monitoring parameters in F.A.C.62-0699.310
- Chemical costs alum for P removal at \$1.80/lb; Symclosene (chlorine) at \$2.50/lb; methanol at \$0.15/lb

For the new-plant alternatives, the data show that the two attached-growth processes (Systems 7 and 8) have the lowest O&M costs, which was due to lower costs for electricity, solids handling, and laboratory analyses. These processes are also simpler to operate than suspended-growth processes. O&M costs are highest for the four-stage (System 2) and deep-bed filtration (System 6) systems because they are the most complex to operate and maintain. For the same reason, the deep-bed retrofit alternative (System 2R) has higher estimated O&M costs than the MLE retrofit system (System 1R).

On a unit cost basis, the nutrient removal systems with filtration included are approximately 20 to 40% more costly than a conventional secondary treatment system without filtration. For the two lowest new-plant capacities analyzed (4,000 and 10,000 gpd), the attached-growth processes (Systems 7 and 8) appear to have clear life-cycle and unit cost advantages over the other nutrient removal technologies. These alternatives are followed by the intermittent-cycle, MLE, and SBR systems (Systems 5, 1, and 4) in a middle cost range. The highest cost systems in this flow range are the four-stage (System 2) and denitrification filter (System 6) systems. As plant capacity increases to approximately 25,000 gpd or greater, the total cost advantage of the attached-growth systems begins to disappear. The four-stage continuous-flow process (System 2) is consistently more costly than all other technologies across all facility sizes.

For the retrofit alternatives, the annual and unit costs operating a denitrification filter are nearly twice those retrofitting and operating an MLE system.

Ranking

Weighted rankings for the seven new treatment pla alternatives and the two plant retrofit alternatives were propared using five criteria that considered both cost and no cost factors associated with the ownership, operation, as performance of small-flow nutrient removal treatment plant. The criteria evaluated were unit cost, nitrogen removal peformance, process control flexibility, ease of operation, as land requirements. For each criterion, a relative score of (less favorable) to 5 (very favorable) was assigned to each alternative. The raw scores for each criterion were the multiplied by a weighting factor to amplify the rankings of the rankings of the sevent sevice in the sevent sevice of the sevent seven

more important criteria relative to those of less important criteria. The results are summarized in Tables 5 and 6 for the new-plant an retrofit systems, respectively.

For the new-plant alternatives, the three-stage system (System 3) was ranked the most favorable based on its moderate costs process control flexibility, and ease of operation. The MLE and deep-bed filtration systems (Systems I and 6, respectively) were ranked second and third, respectively. The SBR and intermittent cycle systems (Systems 4 and 5, respectively) were ranked in a tie for fourth. The four-stage system (System 2) was ranked fifth, while the attached-growth systems (Systems 7 and 8) were ranked in a tie for sixth

Among the two retrofit alternatives, the MLE system (System IR) had the best ranking, primarily due to more favorable unit costs and ease of operation.

Strategies For Procurement of a 6.0 MGD Wastewater Treatment Facility

Harold E. Schmidt, Jr., J. Richard Voorhees, Jon D. Fox, and Peter A. Korelich

n 1980 New Smyrna Beach constructed a 4.0 MGD pure oxygen high-rate activated sludge wastewater treatment plant that discharged to the Indian River Lagoon system. To comply with House Bill 3247, the Indian River Lagoon Act, in 1991 the city upgraded the plant to provide advanced secondary treatment and a public access reclaimed water system. Additional expansions were necessitated by population growth in the service

Alternative methods of process optimization to upgrade the existing facilities included pilot testing various configurations $to \, reduce \, nitrogen \, and \, phosphorus. \, Because \,$ of site constraints and process equipment optimization to meet the effluent criteria required by the regulatory agencies, the city decided to make various improvements to the wastewater transmission system and $to construct a new 6.0 MGD \, treatment \, facil-\\$ ity. The deadline to have the new facility on line was June 30, 1999, per an imposed Consent Order.

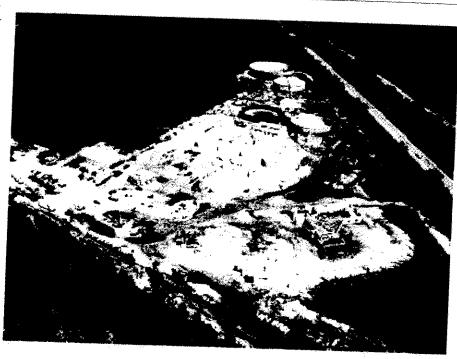

The improvements to the wastewater transmission system consisted of permitting and design of two wastewater pump stations, with pumping capacities of 3.0 and 15 MGD, and various improvements to existing stations. The city's engineering staff provided in-house design for 95,200 linear feet of 12-, 24-, and 30-inch diameter pipelines for raw wastewater, reclaimed water, and potable water transmission mains.

Development of the new facility consisted of site selection, ecological assessments, and resolution of various site zoning issues. Engineering service included permitting and design of a pretreatment structure, a fivestage biological nutrient removal wastewater treatment system, secondary clarifiers, continuous backwash deep bed filters, and high-level disinfection. The nutrient removal system consisting of fermentation, first anoxic, aeration, second anoxic, and reaeration basins.

The design was to provide advanced levels of treatment because of the effluent requirements for wet weather discharge into the Indian River Lagoon system and Class I reliability requirements. Also included was a Class B sludge stabilization facility consisting of sludge holding, sludge thickening, and lime stabilization.

The reclaimed water reuse system consisted of a 6.0-million-gallon substandard effluent storage tank, a 2.0-million-gallon reclaimed water storage tank, and high ser-

Harold E. Schmidt, Jr., P.E., is a vice president, J. Richard Voorhees, P.E., and Jon D. Fox, P.E., are associates, all with Hartman & Associates, Inc., Orlando, Peter A. Korelich, P.E., is the chief engineer for the New Smyrna Beach Utilities Commission.

vice pumping. The reclaimed water high service pumping facilities consisted of five vertical turbine pumps ranging in capaci $ties from\,450\,to\,2,000\,gpm.\,Ancillary\,facili$ ties included a new administration building, a laboratory for both wastewater and potable water, motor control centers, and other miscellaneous facilities.

The overall wastewater management program was funded using a combination of methods. It included funds from the city's mandated facility surcharges and renewal and replacement accounts), utility system $revenue\,bonds, the\,State\,Revolving\,Fund,$ and a grant from the St. Johns River Water Management District.

Objectives

The success of a wastewater management design depends on development of a thorough and coordinated set of engineering drawings and specifications, selection of equipment, choice of contractor, and $owner's commitment to proper operation. \\ A$ project still may not meet all expectations $because of hidden \, problems \, that \, enter \, into \,$ the project as contractors prepare the bids. Our goal was to develop a format that prevented poor quality or misapplied equipment from being included in the project. while maintaining a high level of competition between the equipment manufacturers and suppliers.

The method of procurement itself can become an impediment to a successful project. The conventional open format commonly used in the bidding of wastewater management systems generally encourages selection of only the lowest priced materials, methods of construction, and equipment. Problems sometimes develop and extend through construction and operation. For example, when the term "or equal" is added to a well-written specification, it may become vague to the reader. During the bidding process, the contractor will receive many quotes from many suppliers of the equipment named in the specifications and/ or interpreted as an "equal" to the specified equipment, and thus must select the lowest priced equipment or package to be selected for the project. Therefore, little consideration is given to the equipment that best $meets\,the\,requirements\,of\,the\,project.\,Most$ important, needs of the owner, who must operate and maintain the facilities, are ignored. Based on information from the U,S_{\cdot} Accounting Office, one of the most signifi-
